CT: Chemotherapy HT: Hormonotherapy

There was 40.4% discordance between pre- and post-test recurrence risk groups. In addition, intrinsic subtypes were 34.6%
discordant, which is largely driven by the reclassification of pre-test luminal A tumors into Prosigna luminal B group.

**Conclusions:** Although conventional risk assessment methods are relatively inexpensive with shorter turnaround times, their accuracy for risk assessment and value for risk reduction are suboptimal. According to our results, Prosigna assay was found as a relevant tool for clinical decision-making process. In cases where there is a discrepancy between the clinical assessment results and the Prosigna assay, tumor boards may guide treatment recommendations. Long term follow-up of these patients will elucidate the potential benefits of using multigene molecular tests as biomarkers for EBC treatment.
Mutational characterization of HER2-positive breast cancer

Background: Studies of mutational analysis have been widely reported in various global series of breast cancer. However, in the era of different phenotypes of breast cancer, these analyses should be more specific in order to find differences in each phenotype that could predict response to treatment. Particularly HER2 positive is a special subtype with different connotations that make the analysis of its genotype very interesting.

Methods: Cohorts of 47 consecutive samples of HER2 positive breast cancer, treated in our institution were analyzed. It was conducted a mutational study with NGS technique of the most common genes involved in breast cancer.

Results: 10 patients were metastatic at diagnostic, 17 with negative estrogen receptor expression, the median value of Ki67 was 45 (20-95) and the median initial tumor size was 33.5 mm (18-111). Immunohistochemical expression of HER2 was +3 in 31 tumors and +2 in 15 with a median ratio by FISH of 3,2 (1,18-8,3). We also analyzed the expression of HER by PCR of mRNA in 35 samples with a median expression of 2,49 (0,26-33,15). 38 patients underwent surgical excision of the tumor with a pathologic complete response observed in 19.

We found a total of 38 significant mutations and the genes with more frequent mutations were MCPH1 (100%), HNF1 (98%), p53 (96%), somatic BRCA1 (62%), TSC1 (30%), PIK3CA (23%), ATM (21%), ALK (15%) and somatic BRCA2 (13%). Although the aim of the study was to find the most frequent mutations in this subtype, we have also analyzed possible correlations of those with pathological response or with more common variables, finding no significance in any of them.

Conclusions: In our series, we found a high percentage of mutations in MCPH1, HNF1 and p53 genes with almost 100% of mutations in p53 that are also limited in a very specific area. Also interesting is the 62% of mutations found in BRCA1 and 13% in BRCA2 that could allow more specific treatments in this subgroup. Although the study did not have the power to assess the predictive factor of these mutations, it is very suggestive that in the 7 patients with BRCA mutations, 6 achieved a complete pathological response.
MYC dysregulates mitotic spindle function in triple-negative breast cancer creating a dependency on TPX2

Andrei Goga¹, Julia Rohrberg¹, Alexandra Corella¹, Moufida Taileb¹, Seda Kilinc¹, Marie-Lena Jokisch¹, Roman Camarda¹, Alicia Zhou¹, Sanjeev Balakrishnan¹, Aaron N Chang² and Hannah Klein-Connolly¹. ¹University of California, San Francisco, San Francisco and ²University of California, San Diego, San Diego.

Tumors that overexpress the MYC oncogene, including most receptor triple-negative breast cancers, frequently demonstrate aneuploidy, numerical chromosome alterations associated with highly aggressive cancers. Aneuploidy is also associated with rapid tumor evolution and poor patient outcome. We identify that MYC overexpression induces reversible defects in microtubule nucleation and mitotic spindle assembly, in TNBCs and other epithelial cells, promoting chromosome segregation defects, micronuclei and chromosomal instability (CIN). High TPX2 expression is permissive for mitotic spindle assembly and chromosome segregation in cells with MYC overexpression; whereas TPX2 depletion blocks mitotic progression, induces cell death and prevents tumor growth. Attenuating MYC expression reverses mitotic defects, even in established breast tumor cell lines, implicating an ongoing role for high MYC in the persistence of CIN in cancers. Our studies implicate the MYC oncogene as a regulator of spindle assembly and identify a new MYC-TPX2 synthetic-lethal interaction in TNBC that could represent a future therapeutic strategy in MYC-overexpressing cancers. Moreover, our studies suggest that blocking MYC activity can attenuate the emergence of CIN and tumor evolution.
CRISPR-Cas9 mediated \textit{BRCA1} mutation in primary cells: Mutation efficiency and effects

Mi Ran Choi\textsuperscript{1}, Shivangi Yadav\textsuperscript{1}, Ali Shidfar\textsuperscript{1}, Seema A Khan\textsuperscript{1} and Susan E Clare\textsuperscript{1}. \textsuperscript{1}Feinberg School of Medicine, Northwestern University, Chicago, IL.

**Background:** Germline mutations in Breast Cancer Associated (\textit{BRCA}) 1 or 2 genes confer an increased risk of the development of breast and ovarian cancer. Germline mutation is followed by somatic loss of heterozygosity (LOH) resulting in biallelic inactivation. \textit{BRCA1} is involved in multiple homeostatic functions including control of chromatin organization, gene transcription, protein stability and cell division. Recent studies have demonstrated heterogeneity in LOH within and between premalignant and malignant breast tissues of \textit{BRCA1} mutation carriers. We hypothesize that LOH does not have a unitary effect on phenotype but differs by the function that is abrogated.

**Methods:** To test our hypothesis, we adopted CRISPR-Cas9 gene editing technology. The guide RNAs for targeting the exon sequence in the RING finger, nuclear export signal (NES), nuclear localization signal (NLS) and \textit{BRCA1} C Terminus (BRCT) domain/motif of \textit{BRCA1} were designed and synthesized. MCF10A cells were transfected with a complex of guide RNA and Cas9 protein (RNP) to cause in/del mutation. The mutation was analyzed by both T7E1 assay, and an innovative and more precise method developed in our lab that utilizes linked nucleic acids (LNA) and qPCR. Proliferation and apoptosis assays were performed using the transfected cells. Organoids prepared from \textit{BRCA1} mutation carriers also were transfected with RNPs and the mutation burden determined.

**Results:** Since single cell clones of the transfected MCF10A cells could not be selected and expanded, a pool of transfected cells was used for the analyses. T7E1 assay and qPCR analysis using LNAs demonstrated the presence of the mutations. A standard curve was created to enable the calculation of the mutation burden. IncuCyte analysis revealed increased proliferation and apoptosis, induced by irradiation, in cells with the mutation in Exon 10, where the extent of increase varied from 11% to 48% depending on the degree of mutation. In contrast, cells with the mutation in Exon 5 displayed diminished proliferation with no change in apoptosis. That mutations in exon10 and 5 have distinct biological effects when compared to the mutations in other exons is intriguing, and modification of binding proteins will be investigated. Organoids generated from \textit{BRCA1} mutation carriers (primary and nonmalignant cells) were able to be successfully transfected using the NEON electroporation system. Mutations were introduced by the CRISPR-Cas9 system and their extent quantified by our LNA-mediated qPCR method.

**Conclusions:** CRISPR-Cas9-mediated gene editing of \textit{BRCA1} in MCF10A resulted in a change in the proliferation rate and the extent of apoptosis that is dependent on the location of the de novo mutation within the gene. The development of a novel method, LNA-mediated qPCR, provides quantitative information regarding the mutations that may be used to correlate mutation burden with biological functional change. Successful establishment of this \textit{BRCA1} tumorigenesis model has provided us with a method to test other putative tumor suppressors.
RelB facilitates cell migration and invasion in breast cancer via MMP1 upregulation

Mei Wang¹ and Jinhai Tang¹. ¹The First Affiliated Hospital with Nanjing Medical University, Nanjing, China.

Background: RelB is a subunit of the nuclear factor-κB (NF-κB) signaling family and appears aberrant expression in breast cancer. The aim of the present study was to further investigate the role of RelB in breast cancer and whether RelB might be a therapeutic target.

Methods: 120 cases of breast cancer patients were collected from the Jiangsu Province Hospital during 2015-2017. Immunohistochemistry (IHC) was performed to detect RelB expression in breast cancer tissues and para-cancer tissues. The relationship between RelB expression and clinical pathologic parameters were investigated. Detection the expression of RelB in 4 kinds of human breast cancer cell lines (MCF-7, T47D, MDA-MB-231, BT-549) by Western blot and RT-qPCR. Knockout of RelB in TNBC cell lines (BT-549 and MDA-MB-231) was using the CRISPR/Cas9 genome editing system. CCK-8 and flow cytometry were performed to observe the proliferation, cycle and apoptosis of MDA-MB-231 and BT-549 after knockout of RelB. Transwell and wound healing experiments were performed to observe cell invasion and migration ability. RT-PCR and Western blotting were performed to detect the expression of mRNA and protein of EMT marker and MMP1 respectively. The luciferase reporter gene was performed to detect whether RelB binding with MMP1 promoter region. In vivo efficacy was tested using the xenograft model and lung metastasis model.

Results: RelB was highly expressed in triple-negative breast cancer (TNBC) tissues compared with that in adjacent tissues. RelB levels were remarkably associated with the pTNM stage (p=0.01981) and ER expression (p=0.4689). RelB expressions in TNBC cell lines were higher than that of hormone receptor positive MCF-7 cells. In vitro studies showed that RelB deletion promoted apoptosis and suppressed breast cancer cell survival, migration and invasion by decreasing snail, vimentin and MMP1. RelB deletion inhibited cell cycle progression and G1/S transition by upregulating p21 and p27 expression. In vivo studies showed that 231-RelB-KO cells completely impaired tumor formation in xenograft models and lung metastasis model in nude mice.

Conclusion: RelB is aberrant constitutively expressed in clinical specimens and cell lines of breast cancer, especially in TNBC. RelB regulates malignant phenotypes of breast cancer, including cell survival, migration and invasion, as well as apoptosis and the cell cycle. Moreover, RelB can induce MMP1, which facilitates the invasion of tumor. Collectively, our findings highlight that RelB might serve as a therapeutic target for triple negative breast cancer.
Possible role of p53/Mieap-regulated mitochondrial quality control as a tumor suppressor in human breast cancer

Manabu Futamura¹, Siqin Gaowa¹, Hirofumi Arakawa² and Kazuhiro Yoshida¹. ¹Graduate School of Medicine, Gifu University, Gifu, Japan and ²National Cancer Center Research Institute, Tokyo, Japan.

[Background] In sporadic breast cancers, the most important gene is \( p53 \), given that it is a tumor suppressor gene and mutated in greater than 50% of human cancers. According to previous reports, \( p53 \) is also mutated in approximately 20–40% of breast cancers. Recent data from the cancer genome atlas (TCGA) revealed that 37% of breast cancer specimens had alterations in \( p53 \)-particularly, 72% in (human epidermal growth factor) HER2-rich and 80% of basal-like breast cancer cases—indicating that it is a critical driver of tumor development even in breast cancer. \( p53 \) is clinically very important not only because of its high mutation rate but also because mutation is associated with more aggressive disease and worse overall survival.

Mitochondria-eating protein (Mieap) is a \( p53 \)-target gene that plays an important role in mitochondrial quality control. Mieap has been reported to have a critical role in tumorsuppression of colorectal cancer. Here, we investigated the role of Mieap as a tumorsuppressor in breast cancer. [Marerial and methods] We overexpressed Mieap using the constructed adenovirus in breast cancer cell lines such as MCF-7, SK-BR-3, and MDA-MB-231 cells. The percentages of cells in different cell cycle phases (subG1, G1, S, and G2/M) were determined using FACS analysis and also caspase activities (Caspase, 3/7, 9) were measured. Cleaved PARP, which is a marker of cells undergoing apoptosis, was detected by western blot. For in vivo experiments, we examined the expression of Mieap using surgical specimens (invasive ductal carcinomas (IDCs): 75, ductal carcinoma in situ (DCIS): 27, fibroadenomas (FAs): 18) by immunohistochemistry. Next, we performed methylation-specific PCR (MSP) for Mieap, NIX, and BNIP3 promoters and p53-mutation search using 46 samples that were cryopreserved, among 75 IDC cases used for immunohistochemistry. These studies were approved by the central ethics committee of Gifu University. [Results] The enforced-expression of exogenous Mieap in breast cancer cells induced caspase-dependent apoptosis, with activation of both caspase-3/7 and caspase-9. Immunohistochemistry revealed endogenous Mieap in the cytoplasm in 24/75 (32%) invasive ductal carcinomas (IDCs), 15/27 (55.6%) cases of ductal carcinoma in situ (DCIS), and 16/18 (88.9%) fibroadenomas (FAs) (IDC vs DCIS: 27, fibroadenomas (FAs): 18) by immunohistochemistry. Next, we performed methylation-specific PCR (MSP) for Mieap, NIX, and BNIP3 promoters and p53-mutation search using 46 samples that were cryopreserved, among 75 IDC cases used for immunohistochemistry. These studies were approved by the central ethics committee of Gifu University. [Results] The enforced-expression of exogenous Mieap in breast cancer cells induced caspase-dependent apoptosis, with activation of both caspase-3/7 and caspase-9. Immunohistochemistry revealed endogenous Mieap in the cytoplasm in 24/75 (32%) invasive ductal carcinomas (IDCs), 15/27 (55.6%) cases of ductal carcinoma in situ (DCIS), and 16/18 (88.9%) fibroadenomas (FAs) (IDC vs DCIS: p = 0.0389, DCIS vs FA; p = 0.0234, IDC vs FA; p < 0.0001). In IDCs, the Mieap promoter was methylated in 6/46 (13%) cases whereas p53 was mutated in 6/46 (13%) cases. Therefore, the p53/Mieap-regulated mitochondrial quality control pathway was inactivated in 12/46 IDCs (26.1%). Interestingly, all of the tumors derived from the 12 patients with the Mieap-promoter methylation or p53 mutation pathologically exhibited more aggressive and malignant phenotype of breast cancers, resulting in significantly shorter disease-free survival (DFS) (p = 0.021). [Conclusion] These results indicate that p53/Mieap-regulated mitochondrial quality control has a critical role in tumor suppression of breast cancer, possibly in part, through mitochondrial apoptotic pathway.
CXCL1 chemokine stimulates migration and invasion in ER-negative breast cancer through activation of the ERK/MMP-2/9 signaling axis

Shengchun Liu¹, Chengcheng Yang¹, Shipeng Guo¹ and Rui Chen¹. ¹The First Affiliated Hospital of Chongqing Medical University, Chongqing, China.

Chemokine (C-X-C motif) ligand 1 (CXCL1), a member of the CXC chemokine family, has been reported to be a critical factor in inflammatory diseases and tumor progression. However, its functions and molecular mechanism in estrogen receptor α (ER) negative breast cancer (BC) has little been known. In this study, we discovered that CXCL1 is overexpression in ER-negative breast cancer tissues and cell lines compared with ER-positive patient tissues and cell lines. Treatment with recombinant human CXCL1 protein promotes ER-negative BC cell migration and invasion in dose-dependent manner and stimulates the activation of p-ERK1/2, but not p-STAT3 or p-AKT. Whereas, knockdown of CXCL1 in BC cells attenuates these effects. Moreover, CXCL1 induces the expression of MMP2/9 via ERK1/2 pathway. The blockage of ERK by its antagonists (U0126) can abolish the effect of CXCL1 on MMP2/9 expression. Furthermore, immunohistochemical (IHC) analysis reveals a strong positive correlation between CXCL1 and p-ERK1/2 expressions in BC tissues. In conclusion, our study illustrates that CXCL1 is highly expressed in ER-negative BC and stimulates cell migration and invasion through ERK/MMP2/9 pathway, which may serve as a potential therapeutic target in ER-negative breast cancer.
The role of MLK4 amplification in progression of triple negative breast cancer

Monika K Prelowska, Dawid Mehlich, Michal Lazniewski, Klaudia Kaminska, Adam S Gorczynski, Aleksandra Korwat, Olga Sokolowska, Jakub Golab, Wojciech Biernat, Dariusz Plewczynski, John Brognard, Dominika Nowis, and Anna A Marusiak.

Centre of New Technologies, University of Warsaw, Warsaw, Poland; Medical University of Warsaw, Warsaw, Poland; Postgraduate School of Molecular Medicine, Medical University of Warsaw, Warsaw, Poland; Medical University of Gdansk, Gdansk, Poland; Medical University of Warsaw, Centre for Preclinical Research and Technology, Medical University of Warsaw, Warsaw, Poland; Faculty of Mathematics and Information Science, Warsaw University of Technology, Warsaw, Poland and National Cancer Institute, Frederick, Maryland.

Mixed Lineage Kinase 4 (MLK4) is a serine/threonine kinase that plays a role in a variety of cellular processes, including migration, apoptosis and proliferation. It belongs to the family of MAP3 kinases, which regulate the activity of specific MAPKs (mitogen-activated protein kinases). MLK4 is the least described member of the family and it was proved to act as a functional MAP3 kinase that activates the JNK, ERK and NFκB pathways. The rationale of this project is based on the recent data showing gene amplification and mRNA upregulation of MLK4 in invasive breast carcinoma at the frequency of 23%. Here, we performed a series of experiments aiming to characterize the role of MLK4 in breast cancer development and progression. We started from identification of breast cancer cell lines that express high endogenous level of MLK4. Since clinical data indicated that MLK4 expression was higher in triple-negative breast cancer (TNBC), comparing to other breast cancer subtypes, we decided to further study the role of MLK4 in TNBC. We have generated cell lines with doxycycline-inducible knock-down of MLK4, HCC1806 and HCC1599, and we found that MLK4 depletion resulted in reduced cell proliferation. We also observed that the knock-down of MLK4 in these conditions caused the reduction in size of the spheroids. Moreover, we noticed that when MLK4 is depleted in HCC1806 cells, the migration and invasion was significantly impaired. Lastly, our results of immunohistochemistry in samples from breast cancer patients showed that higher levels of MLK4 in TNBC samples significantly correlated with the occurrence of lymph node metastasis. Currently, we are investigating molecular pathways such as JNK, MEK/ERK and NF-κB, that might be affected by knock-down of MLK4. Collectively, our findings indicate that high levels of MLK4 promote aggressive phenotype of breast cancer cells, by increasing their migratory and invasive potential.
Single-cell profiling identifies hypoxic carcinoma cells as source of an immunosuppressive VEGFA metagene

Thomas Karn, Carsten Denkert, Bruno V Sinn, Karsten Weber, Valentina Nekljudova, Achim Rody, Tobias Meissner, Christos Hatzis, Ahmed El-Balat, Sven Becker, Christine Solbach, Michael Untch, Andreas Schneeweiss, Gunter von Minckwitz, Sibylle Loibl, Lajos Pusztai, and Uwe Holtrich. 1Goethe University, Frankfurt, Germany; 2Charite University, Berlin, Germany; 3German Breast Group, Neu-Iseinsburg, Germany; 4University Hospital Schleswig-Holstein, Lübeck, Germany; 5Avera Cancer Institute, Sioux Falls, SD; 6Yale Cancer Center, New Haven, CT; 7Helios Kliniken, Berlin-Buch, Germany and 8Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany.

Background:
We have previously shown that expression of the IL8/VEGFA-metagene eliminates the good prognostic effect of TILs in TNBC (PMID 21978456, 28750120). We also showed that the VEGFA metagene predicted response to neoadjuvant bevacizumab in the GeparQuinto trial (Karn 2017 SABCS #851166). The main cellular sources of the transcripts that comprise the VEGFA metagene are unknown since mRNA profiling of bulk biopsies contains signals from different cell types.

Methods:
Individual genes that comprise the VEGFA metagene were measured in bulk tissue- and single cell-RNA-Seq from breast cancer subtypes and normal cells on different platforms (Affymetrix n=4915, Agilent n=597, Illumina n=2433, RNA-Seq n=1215, Exome Capture RNA-Seq n=226, HTG-Seq n=243, sc-RNA-Seq n=24710). For blinded, orthogonal validation we performed immunohistochemistry. Effect of neoadjuvant chemotherapy with or without bevacizumab was studied by RNA-Seq and IHC on samples from GeparQuinto trial. SWOG S0800 (GSE114403), PROMIX (GSE87455), and GeparSixto trials were used for validation. TCGA was mined for mutations and somatic CNA. RNA-Seq from GeparNuevo was used for correlation with checkpoint inhibitor treatment.

Results:
We identified a stable core of six genes (VEGFA, ANGPTL4, ADM, NDRG1, DDIT4, CSTB) in different cohorts. Strong expression of this signature was mainly restricted to TNBC subtype and associated with poor prognosis within this subgroup. Single cell RNA-Seq of breast epithelial cells from 4 reduction mammoplasties and 4 TNBC revealed that these genes are coexpressed in individual epithelial cells and not associated with endothelial cells. In line with their presumed functions in cellular stress and hypoxia, immunohistochemistry revealed strong para-necrotic expression in TNBC. Moreover, high gene expression in TNBC was associated with mutations in DNA damage control pathways, somatic copy number alterations, and lower TILs. While chemotherapy led to downregulation, bevacizumab increased expression. In multivariate analysis, high pretreatment values predict pCR to both bevacizumab and chemotherapy (OR 2.40, P=0.006), which may be explained by sensitivity of tumors which are already under cellular stress. On the other hand, expression of the VEGFA metagene seems to create an immunosuppressive environment that counteracts the positive prognostic effect of TILs. In pre-treatment biopsies from the GeparNuevo checkpoint inhibitor trial we found a negative correlation of VEGFA metagene expression with the amount of the recently identified tissue-resident memory T cell subset (CD8<sub>TRM</sub>, PMID 29942092; P=0.002), while the subsequent increase of CD8<sub>TRM</sub> during treatment was larger in tumors with high VEGFA (P=0.019).

Conclusions:
Perinecrotic carcinoma cells under stress from hypoxia and or chromosomal instability are the source of the VEGFA metagene signature. Its predictive value in TNBC suggests estimating and reporting the amount of necrosis in the pathology report may be helpful in predicting response to preoperative chemotherapy, and could be used as stratification factor in clinical trials. The signature indicates an immunosuppressive environment and should be further studied in the context of immune therapies in combinations with anti-angiogenic treatment.
Identifying breast cancer molecular phenotypes to predict response in a modern treatment landscape: Lessons from ~1000 patients across 10 arms of the I-SPY 2 TRIAL

Denise M Wolf¹, Christina Yau¹, Julia Wulfkuhle², Emmanuel Petricoin², Michael Campbell¹, Lamorna Brown-Swigart¹, Gillian Hirst¹, Smita Asare³, Zelos Zhu¹, Evelyn P Lee¹, Amy Delson¹, Paula Pohlmann⁹, I-SPY 2 TRIAL Consortium³, Nola Hylton¹, Minetta C Liu⁸, Fraser Symmans⁴, Angela DeMichele⁵, Douglas Yee⁶, Don Berry⁷, Laura Esserman¹ and Laura van ‘t Veer¹.
¹University of California, San Francisco; ²George Mason University, Fairfax; ³QuantumLeap Healthcare Collaborative, San Francisco; ⁴University of Texas, MD Anderson, Houston; ⁵University of Pennsylvania, Philadelphia; ⁶University of Minnesota, Minneapolis; ⁷Berry Consultants, LLC, Austin; ⁸Mayo Clinic, Rochester and ⁹Georgetown University, Washington, DC.

Background: The explosion in new treatment options targeting immune checkpoints, HER signaling, DNA repair deficiency, AKT, and other pathways calls for updated breast cancer subtypes beyond HR and HER2 status to predict which patients will respond to which treatments. Here we leverage the I-SPY 2 TRIAL biomarker program over the past 8 years across 10 treatment arms to elucidate a minimal set of biomarkers that may improve response prediction in a modern treatment context, and to investigate which new patient phenotypes are identified by these response-predictive biomarkers.

Methods: 986 patients were considered in this analysis. Treatments included paclitaxel alone (or with trastuzumab (H) in HER2+) or combined with investigational agents: veliparib/carboplatin (VC); neratinib; MK2206; ganitumab; ganetespib; AMG386; TDM1/pertuzumab (P); H/P; and pembrolizumab (Pembro). 24 prospectively defined, mechanism-of-action and pathway-based expression and phospho-protein signatures/biomarkers assayed from pre-treatment biopsies were previously found to be predictive in a particular agent/arm in pre-specified analysis. Here we evaluate these biomarkers in all patients. We assessed association between each biomarker and response in the population as a whole and within each arm and HR/HER2 subtype using a logistic model. To identify optimal dichotomizing thresholds for select biomarkers, 2-fold cross-validation was repeated 500 times. Our analysis is exploratory and does not adjust for multiplicities.

Results: Our initial set of 24 predictive biomarkers reflects DNA repair deficiency (n=2), immune activation (n=7), ER signaling (n=2), HER2 signaling (n=4), proliferation (n=2), phospho-activation of AKT/mTOR (n=2), and ANG/TIE2 (n=1) pathways, among others. Biomarkers reflecting similar biology are correlated and cluster together. We make use of this correlation structure to reduce the dimensionality of the biomarker set to five predictive signals: proliferation, DNA repair deficiency (DRD), immune-engaged (Immune+), luminal/ER (lum), and HER2-activated. These biomarkers, when dichotomized, identify patient groups with differential predicted sensitivities to I-SPY 2 agents and are present at different proportions within receptor subtypes. For instance, in the HER2- subset, Immune+/DRD+ patients are predicted sensitive to both VC and Pembro, and account for 39% of TN, but only 12% of HR+HER2-. On the other end of the spectrum, only 17% of TN are Immune-/DRD-, compared to the majority (56%) of HR+HER2-. There are also subsets of patients positive for only one marker. For the HER2+ subset, 67% are HER2-activated+, and 25% lum+; of these HER2-activated+ patients are more likely to be Immune+ (44%), vs 23% in lum+.
HER2-activated+/Immune+ patients have higher predicted sensitivity to HER2-targeted agents than lum+ or Immune- patients. In all, these molecular phenotypes predict sensitivity to one or more I-SPY 2 investigational agents for 75% of the ~ 1000 patients.

Conclusion: Molecular phenotypes reflecting proliferation, immune engagement, HER2-activation, luminal/ER-signaling, and DNA repair deficiency may provide a roadmap to guide treatment prioritization for emerging therapeutics.
Different pCR rates according PAM50 defined subtypes in HER2 positive early breast cancer treated with neoadjuvant pertuzumab and trastuzumab

Tamara Díaz-Redondo1, Rocio Lavado-Valenzuela2, Nuria Ribelles1, Tomas Pascual3, Fernando Galvez4, Alejandro Falcón5, María C Alamo6, Carmen Morales7, Marta Amerigo8, Aleix Prat3 and Emilio Alba1. 1Unidad de Gestión Clínica Intercentro de Oncología, Hospitales Universitarios Regional y Virgen de la Victoria de Málaga, Malaga, Andalucía, Spain; 2Instituto de Investigación Biomédica de Málaga (IBIMA), Hospitales Universitarios Regional y Virgen de la Victoria de Málaga, Malaga, Andalucía, Spain; 3Hospital Clinic de Barcelona, Translational Genomics and Targeted Therapeutics in Solid Tumours Lab (IDIBAPS), Barcelona, Spain; 4Hospital Ciudad d Jaen, Jaén, Andalucía, Spain; 5Hospital Universitario Virgen del Rocío, Sevilla, Andalucía, Spain; 6Hospital Universitario Virgen Macarena, Sevilla, Andalucía, Spain; 7Hospital Reina Sofía, Cordoba, Andalucía, Spain and 8Hospital Juan Ramón Jiménez, Huelv, Andalucía, Spain.

BACKGROUND
We aim to compare the benefit of adding pertuzumab (P) to the standard neoadjuvant treatment with trastuzumab (T) in patients (pt) with early immunohistochemically (IHC) defined HER2+ breast cancer (BC) in the different intrinsic molecular subtypes defined by PAM50 gene expression analysis.

METHODS
Two hundred forty-four pt. with IHC HER2 positive BC, stage I-IIIC, diagnosed in 8 Spanish hospitals were consecutively treated with neoadjuvant chemotherapy (NAC) plus antitargeted HER2 therapy. Cohort A (n=128) received NAC+T and Cohort B (n=116) received NAC+T+P. All the patients were classified into intrinsic molecular subtypes based on the PAM50® signature made in the diagnostic biopsies. Rate of pathologic complete response in breast and axilla (pCR) in the different PAM50 subtypes was compared by ChiSquared and Fisher test. A multivariate logistic regression model was used to analyze the potential effects of the covariates over the pCR rates.

RESULTS
Characteristics of the patients and intrinsic molecular subtypes are shown in

Clinicopathologic and treatment characteristics of patients

The overall pCR rate was significantly higher in cohort B vs A (61% vs 39%, p=0.0009). The pCR rate in the HER2E was 50% for T and 75% for T+P (p=0.003) and 11% for T and 42% for T+P (p=0.004) in Luminal subtype. In the multivariate analysis, the improvement pCR rates was highly associated with type of treatment (cohort) (p=0.0015, OR:2.44) and were not related to clinicopathologic covariates (tumor stage, hystological grade, HR) (p>0.05). These results were confirmed for the HER2enriched subtype (p=0.00398, OR:2.94) and even more strongly for Luminals (p=0.0026, OR:13.41).

CONCLUSIONS:
1. The highest pCR was reached by the PAM50HER2E patients treated with T+P.
2. In Luminal subtype the improvement of pCR is strongly associated with the used of P and this association is independent of clinical covariates.
The fully validated NSABP/NRG 8-gene signature which predicted the degree of benefit in the adjuvant setting (B-31 and NCCTG N9831) associates with pCR in the neoadjuvant setting in NSABP clinical trial FB-7

Katherine L Pogue-Geile1, Ying Wang1, Ashok Srinivasan1, Patrick G Gavin1, Rim S Kim1, Nan Song1, Huichen Feng1, Corey Lipchik1, Joseph P Costantino1,2, Norman Wolmark1, Peter C Lucas1,3, Soonmyung Paik4 and Samuel A Jacobs1. 1NSABP/NRG Oncology, Pittsburgh, PA; 2The University of Pittsburgh, Pittsburgh, PA; 3University of Pittsburgh School of Medicine, Pittsburgh, PA and 4Yonsei University College of Medicine, Seoul, Republic of Korea.

**Background:** We previously described a predictive signature for trastuzumab benefit which was validated in the adjuvant setting in an independent cohort within NSABP B-31 (the 8-gene signature) (Pogue-Geile et al JNCI, 2013) and in Alliance/NCCTG N9831 (SABCS 2017). The 8-gene signature subtyped B-31 patients into three trastuzumab benefit groups: high HR=0.27, intermediate HR=0.56 and no benefit HR=1.56 based on disease free survival. The 8 gene signature was also predictive of trastuzumab benefit in N9831. HRs were 0.47, P<0.001, 0.6, P=0.02, and 1.54, P=0.375 in the predicted-high, -intermediate and -no benefit groups, respectively based on recurrence free survival (SABCS 2017). The interaction P-value was significant at 0.019 in adjusted Cox models. The RFS at 10 years for trastuzumab-treated pts was 83%, 83% and 72% in the high, intermediate and no benefit groups, respectively. Now we have tested the association of the 8-gene signature groups with pCR in FB-7 which was a 3 arm neoadjuvant study testing the pCR rate of HER2+ breast cancer patients treated with paclitaxel in combination with trastuzumab (T) or neratinib (N) or the combination (T + N).

**Methods:** RNA-Seq data from FB-7 pretreatment biopsies was used to predict the trastuzumab benefit groups (high, intermediate, and no) for each patient's tumor using the 8 gene signature using methods and cut-offs as previously described (Pogue-Geile et al 2013). The pCR rates (percentages) were tested for treatment interaction with a chi-square test.

**Results:** The pCR rates were 75%, 53%, and 22%, in the high (N=12), intermediate (N=32) and no benefit groups (N=9), respectively, when analyzed without regard to treatment arm. The pCR rates for the no benefit group and the high benefit groups were significantly different (p=0.030) and there was a significant treatment interaction with the 8-gene benefit group (intp=0.0081). The predicted low and intermediate groups were combined to test whether the 8 gene signature could identify a group of patients whose pCR rates might improve by adding N to T, and referred to it as the low benefit group. This was necessary due to the small numbers of patients in each group. The pCR rate in the low benefit group was higher in patients treated with T+N (9/15, 60%) than in the T arm (6/11, 45%) but these differences were not significant.

**Conclusions:** This is the first test of the 8-gene signature in the neoadjuvant setting and interpretations of these data should be interpreted cautiously due to the small numbers. However, if these results were validated in another neoadjuvant trial then the 8 gene signature could provide a rationale for selecting patients who would be appropriate for the addition of neratinib or other TKIs to trastuzumab and chemotherapy.

BRCA1/2 alterations are present at significant rates across breast cancer subtypes and are associated with a high genome-wide loss of heterozygosity signature

Ethan S Sokol¹, Garrett M Frampton¹, Jeff Ross¹, Siraj Ali¹, Jon Chung¹ and Steffi Oesterreich². ¹Foundation Medicine, Cambridge, MA and ²University of Pittsburgh, Pittsburgh, PA.

Background
The recent approval of PARP inhibitor, olaparib, in HER2-negative breast cancer expands the therapeutic options for patients with germline BRCA1/2 alterations. The role of somatic BRCA alteration as a predictive biomarker in breast cancer is currently unclear. NCCN guidelines call for germline testing in all young patients (<46 yrs) and patients with triple negative breast cancer (TNBC) (< 61 yrs) with a personal history of breast cancer. Here we examined the landscape of BRCA mutations to assess whether additional populations may have potential benefit from PARP inhibitors.

Methods
Hybrid-capture based comprehensive genomic profiling of 395 cancer-related genes using the FoundationOne assay (Foundation Medicine, MA) was performed on 12,508 breast carcinomas. Somatic/germline/zygosity status for BRCA1/2 variants was analyzed as described in Sun, 2018 (PMID: 29415044). High genome-wide loss-of-heterozygosity (gLOH) was classified as ≥16% LOH. Subgroups were analyzed on histological (Invasive Ductal Carcinoma (IDC), Invasive Lobular Carcinoma (ILC)) and molecular subtypes [ER-positive (ER+), HER2-amplified (HER2+), TNBC], patient age [≤45, 46-60, 61+], and gender.

Results
Consistent with previous reports, the frequency of BRCA1/2 alterations was highest in young patients (<46; 15%), TNBC (10%), and male breast cancer (14%); BRCA1/2 alterations were also identified in HER2+, ILC, and ER+ tumors (5.3%, 6.5%, 8.3%). Overall, BRCA1 was more frequently mutated in TNBC and young patients (67%), whereas BRCA2 was more frequently mutated in ER+, HER2+, ILC, and male breast cancer (63%, 57%, 79%, 100%).

The fraction of somatic BRCA mutations (sBRCA) was 38%, with the lowest fraction of sBRCA in TNBC and young patients (30%, 30% overall, 36%, 42% for BRCA1) and highest in HER2+, ILC, and older patients (46%, 52%, 51%); the absolute frequency of sBRCA is approximately 3.5%. In tumors with ESR1 mutations, we detected concurrent BRCA mutation in 6.4% (85/1319), with 48% predicted somatic.

Almost all tumors with BRCA mutations had biallelic inactivation, with LOH of the second allele irrespective of predicted germline status (90% of gBRCA and 86% of sBRCA under LOH). gLOH score was used as a phenotypic measure of homologous recombination deficiency (HRD): patients harboring biallelic BRCA alterations had elevated rates of gLOH with 89% of gBRCA and 84% of sBRCA tumors harboring a high gLOH score, vs 47% with heterozygous BRCA, 34% with no BRCA alteration, and 80% for patients with BRCA deletion.

Conclusions
Thirty-eight percent of deleterious BRCA alterations in breast are predicted somatic, including 36% of BRCA1 alterations in TNBC. Germline testing would miss these alterations even though they are frequently under LOH and are associated with high gLOH, a biomarker with predictive value in ovarian cancer. While patients with ER+ and HER2+ tumors have low rates of gBRCA alterations, the overall BRCA mutation rate, including somatic alterations, is appreciable at 8.3% and 5.3%. Our findings demonstrate that sBRCA alterations are associated with a comparable HRD phenotype to gBRCA alterations and suggests that PARP inhibitors may have potential value for a wider range of breast cancer patients.
Expression-based immune signatures as predictors of neoadjuvant targeted-/chemo-therapy response: Experience from the I-SPY 2 TRIAL of ~1000 patients across 10 therapies

Christina Yau¹, Denise M Wolf¹, Michael Campbell¹, Peter Savas², Suling Lin², Lamorna Brown-Swigart¹, Gillian Hirst¹, Smita Asare³, Zelos Zhu¹, I-SPY 2 TRIAL Consortium³, Sherene Loi², Angela DeMichele⁴, Douglas Yee⁵, Don Berry⁶, Laura Esserman¹ and Laura van ‘t Veer⁷. ¹University of California, San Francisco; ²University of Melbourne, Melbourne, Australia; ³QuantumLeap Healthcare Collaborative, San Francisco; ⁴University of Pennsylvania, Philadelphia; ⁵University of Minnesota, Minneapolis and ⁶Berry Consultants, LLC, Austin.

Background: Expression-based signatures have been shown to predict neoadjuvant therapy response; but further studies are needed to deconvolve the contribution of different immune cell types. The I-SPY 2 TRIAL is a standing neoadjuvant platform trial which evaluates experimental agents/combinations when added to standard chemotherapy. In this study, we compared published T/B cell-related signatures at 3 different levels of resolution as predictors of response in the I-SPY 2 TRIAL: (1) a combined T/B-cell co-expression module, correlated with general lymphocytic infiltrate, (2) individual T-cell and a B-cell specific signatures derived from purified immune cells and refined using tumor expression, and (3) 9 T cell subpopulation-specific signatures, including a CD8+ T resident memory phenotype (TRM) and a CD8+ T effector memory subset (TEM), generated from microdroplet-based single cell (sc) RNA sequencing of over 6000 tumor associated CD3+ T cells.

Methods: Expression data from 989 I-SPY 2 patients randomized to one of 9 possible experimental arms or the standard chemotherapy control were available for analysis. Pre-treatment biopsies were assayed using Agilent gene expression arrays. All I-SPY 2 biomarker analyses follow a pre-specified analysis plan. We used logistic modeling to assess each signature as a predictor of pCR within each arm (likelihood ratio test p<0.05). This analysis is also performed adjusting for HR/HER2 status, and within receptor subsets. Our sample size for each arm is small; and our statistics are descriptive rather than inferential. Our analysis is exploratory and does not adjust for multiplicities of other biomarkers outside this study.

Results: In the population as a whole, immune signatures predict response across multiple classes of agents (8/10 arms), including the checkpoint inhibitor Pembrolizumab (Pembro). However, the cell-type and subpopulation-specific signatures most predictive of response vary by subtype and agent. For instance, the T/B-cell co-expression module associates with response to Pembro and the Angiopoetin-1/-2 inhibitor AMG-386 in both HR-HER2- and HR+ERHHER2- subtypes. However, in the HR-HER2- subtype, the T-cell signature and the sc-derived CD8-TRM signature are most predictive; whereas in the HR+HER2- subtype, it is the B-cell, CD8-TRM and a novel CD4 signature that are most strongly associated with response. In the HER2+ subtype, the T/B-cell module and B-cell signature is associated with response to the AKT-inhibitor MK2206. Interestingly, among the sc-derived signatures, it is the CD8-TEM and multiple CD4 population-specific signatures, rather than CD8-TRM, that associate with response.

Conclusion: Our exploratory study suggests that immune signatures are associated with response to multiple I-SPY 2 experimental agents and implicates different immune cell types as response-predictive within breast cancer subtypes. Single cell sequencing derived population specific signatures may help further de-convolute how different immune cell types contribute to therapy responsiveness.
A 3-gene DNA methylation signature fails to predict response to bevacizumab in metastatic breast cancer patients treated within the TANIA phase III trial

Simon P Gampenrieder¹, Risch Angela², Gabriel Rinnerthaler¹, Hubert Hackl³, Markus Steiner¹, Walter Pulverer⁴, Andreas Weinhaeusel⁴, Eva Klinglmayr², Tanja Karl³, Suzana Ilic⁴, Clemens Hufnagl⁵, Cornelia Hauser-Kronberger⁵, Alexander Egle¹ and Richard Greil¹. ¹Hemostaseology, Rheumatology and Infectious Diseases, Oncologic Center, Paracelsus Medical University Salzburg, Salzburg, Austria; ²University of Salzburg, Salzburg, Austria; ³Biocenter, Medical University of Innsbruck, Innsbruck, Austria; ⁴Center for Health & Bioresources, Business Unit for Molecular Diagnostics, AIT – Austrian Institute of Technology GmbH, Vienna, Austria and ⁵Paracelsus Medical University Salzburg, Salzburg, Austria.

Background: Biomarkers predicting response to bevacizumab containing therapy in metastatic breast cancer (MBC) are of urgent need. In a retrospective single-institution analysis we have previously shown that a 3-gene methylation signature (MLH1, POLK and TMBIM6) could discriminate between responders and non-responders to a bevacizumab-based therapy in two independent cohorts of patients with MBC with an AUC of 0.94 and 0.86, respectively (Gampenrieder SP et al. Theranostics. 2018. 8(8):2278-2288). Here, we present the validation of these findings within the prospective phase III trial TANIA (Vrdoljak E et al. Ann Oncol. 2016. 27(11):2046-52) randomizing 494 patients with HER2-negative MBC to chemotherapy plus bevacizumab or chemotherapy alone for two consecutive treatment lines (second- and third-line). All patients had already received bevacizumab-containing therapy in the first-line setting.

Patients and methods: DNA isolated from archival FFPE tumor samples was available from 200 patients consenting to optional translational research within the TANIA trial. Out of these, 176 samples were collected prior to first-line bevacizumab therapy and were analyzed retrospectively. Sufficient DNA for methylation analysis was available from 124 patients: 64 treated with chemotherapy plus bevacizumab and 60 treated with chemotherapy alone. All samples were isolated from the primary tumor. Quantitative methylation analysis was performed by pyrosequencing on the PyroMark Q24 Advanced System (Qiagen). PFS and OS analyses were performed in both study arms comparing “predicted responders” (PRED_R) versus “predicted non-responders” (PRED_NR) based either on median dichotomization or according to the cutoffs for individual CpG and the combined 3-CpG methylation logistic regression model.

Results: Out of the 124 evaluable patients, 32 (25.8%) were classified as PRED_R and 92 as RED_NR by the 3-gene methylation signature. PRED_R did not have a significantly different second-line PFS (HR 0.95, 95%CI 0.57-1.57; P = 0.84) or OS (HR 0.91, 95%CI 0.51-1.60; P = 0.73) when treated in the bevacizumab-containing study arm compared to PRED_NR. In addition, PRED_R did not show a longer PFS when treated with bevacizumab compared to PRED_R treated with chemotherapy alone (HR 0.95, 95%CI 0.59-1.54; P = 0.83). Furthermore, there was no difference in third-line PFS and the combination of second- and third-line PFS between PRED_R and PRED-NR in the bevacizumab arm. In the control arm, PRED_NR showed a statistically significant shorter PFS compared to PRED_R (HR 0.50, 95%CI 0.22-0.77; P = 0.006), but not OS (HR 0.95, 95%CI 0.51-1.77; P = 0.86).

Conclusion: Our 3-gene methylation signature was not confirmed as predictive biomarker for bevacizumab efficacy in metastatic breast cancer.

(This research project was partially supported by ROCHE Austria GmbH)
Markers of response to CDK4 & 6 inhibition from neoMONARCH: A phase II neoadjuvant study of abemaciclib in postmenopausal women with hormone receptor positive, HER2 negative breast cancer

Sara Hurvitz¹, Miguel Martin², Sameera Wijayawardana³, Manisha Brahmachary³, Philip J Ebert³, Suzanne Young³, Valerie Jansen³ and Dennis Slamon¹. ¹University of California, Los Angeles; ²Hospital General Universitario Gregorio Marañón, Madrid, Spain and ³Eli Lilly and Company, Indianapolis.

**Background:** Combination treatments of endocrine therapy (ET) with CDK4 & 6 inhibitors have improved outcomes in patients with HR+ advanced breast cancer, both as initial therapy and after progression on ET. Abemaciclib is a selective inhibitor of CDK4 & 6 approved on a continuous dosing schedule for the treatment of HR+, HER2- MBC patients (pts), alone or in combination with ET. However, biomarkers that predict benefit from this class of agents remain elusive. We previously reported in the phase II neoadjuvant neoMONARCH study (NCT02441946), after 2 weeks of treatment, abemaciclib, alone or in combination with anastrozole (ANZ), led to a significantly higher rate of complete cell cycle arrest (CCCA, defined as Ki67 ≤2.7%) compared to ANZ alone in early stage HR+, HER2- breast cancer (Martin et al. SABCS 2017). As an exploratory aim of this trial, we evaluated the gene expression analyses in order to determine markers of sensitivity and resistance to therapy.

**Methods:** Serial biopsies were collected at 3 time points: Baseline (BL) - prior to treatment, Early – after 2 weeks of therapy with abemaciclib, ANZ, or abemaciclib+ANZ, and Late – after 2 weeks of initial therapy followed by 14 weeks of abemaciclib+ANZ. RNA was extracted from FFPE tumor biopsies at each timepoint and subjected to a Cell Cycle Associated Gene (CCAG) expression panel using the Modaplex® platform and whole transcriptome RNA sequencing. Ki67 was measured at each time point by immunohistochemistry (IHC). Tumors were categorized by the post-treatment Ki67 expression as either sensitive (Ki67 ≤2.7) or resistant (Ki67 ≥7.4), based upon the IMPACT and POETIC studies. Additionally, tumors intrinsically resistant/sensitive to therapy were also identified.

**Results:** ANZ-treated tumors that did not achieve CCCA at 2 weeks (N= 8) displayed higher expression of the cell cycle associated genes **FOXM1**, **E2F1**, **TOPO2A**, and **RRM2**. The addition of abemaciclib to ANZ decreased gene expression in a majority of the tumors (N=5, 62.5%). Tumors intrinsically resistant to treatment with abemaciclib+ANZ displayed persistently elevated levels of cell cycle associated genes compared to sensitive tumors. Finally, gene expression signature of Rb loss-of-function (Rbsig) and RB1 gene expression levels were associated with sensitivity to abemaciclib.

**Conclusion:** On-treatment Ki67 indicated treatment sensitivity and correlated with cell cycle associated gene expression in sensitive and resistant tumors. These exploratory analyses suggest that gene expression analyses may identify genomic markers for abemaciclib and ET treatment sensitivity and may help inform in which tumors to use abemaciclib.
Relationship between tumor infiltrating lymphocytes (TILs) and response to pembrolizumab (Pembro)+chemotherapy (Chemo) as neoadjuvant treatment (NAT) for triple-negative breast cancer (TNBC): phase Ib KEYNOTE-173 trial

Sherene Loi, Peter Schmid, Javier Cortés, Yeon Hee Park, Eva Muñoz-Couselo, Sung-Bae Kim, Joohyuk Sohn, Seock-Ah Im, Esther Holgado, Theodoros Foukakis, Sherko Kuemmel, Rebecca Dent, Anran Wang, Gursel Aktan, Vassiliki Karantza and Roberto Salgado.

Peter MacCallum Cancer Centre, University of Melbourne, Melbourne, Victoria, Australia; Centre for Experimental Medicine, Barts Cancer Institute, London, United Kingdom; Vall d’Hebron Institute of Oncology (VHIO), Madrid, Spain; Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; Yonsei University College of Medicine, Seoul, Republic of Korea; Seoul National University College of Medicine, Seoul, Republic of Korea; Ramon y Cajal University Hospital, Madrid, Spain; Karolinska University Hospital, Stockholm, Sweden; Klinikum Essen-Mitte, Essen, Germany; National Cancer Centre, Singapore, Singapore and Merck & Co., Inc., Kenilworth, NJ.

Background: Increasing quantities of stromal TILs (sTILs) are associated with higher pathologic complete response (pCR) rates with conventional chemo in early-stage TNBC. We evaluated the association between sTILs and PD-L1 expression with response to pembro+chemo as NAT for TNBC in the KEYNOTE-173 trial (NCT02622074).

Methods: sTILs were quantified using light microscopy of H&E-stained slides from pretreatment and on-treatment (during first 3 weeks of pembro monotherapy) tumor biopsies by a pathologist blind to response data. Pretreatment PD-L1 expression was assessed using the PD-L1 IHC 22C3 pharmDx assay and reported as combined positive score (CPS). Endpoints were pCR rate by ypT0 ypN0 and ypT0/Tis ypN0 and objective response rate (ORR; RECIST v1.1) after the first 4 cycles of NAT (taxane+carboplatin+pembro) by MRI. sTILs and PD-L1 CPS were evaluated as continuous variables. Association between sTILs and PD-L1 CPS with response was assessed using logistic regression and area under the receiver operating curve (AUROC) analyses, with a 1-sided alpha level of 0.10. Correlation between PD-L1 and sTILs was assessed by Spearman's rank correlation coefficient. Multivariate analysis included sTILs (pretreatment and on-treatment) and PD-L1 CPS. Likelihood ratio tests were used to evaluate the added value of factors in predicting pCR rate.

Results: Of 60 total pts, 34 had tumors evaluated for pretreatment sTILs, 52 for PD-L1 CPS, and 33 for both sTILs and CPS. On-treatment sTILs were evaluated in 31 pts. Overall pCR rates were 56.7% and 60% by ypT0 ypN0 and ypT0/Tis ypN0, respectively; ORR was 78.3%. In pts evaluated for sTILs and CPS (individually), pCR rates and ORR were comparable with overall pCR rates and ORR. There was a significant correlation between pretreatment sTILs and PD-L1 CPS (ρ=0.65, P<0.001). Higher pretreatment sTILs were significantly associated with response: ypT0 ypN0 ρ=0.011, ypT0/Tis ypN0 ρ=0.006; ORR ρ=0.061. On-treatment sTILs were also significantly associated with response: ypT0 ypN0 ρ=0.061, ypT0/Tis ypN0 ρ=0.041; ORR ρ=0.031. Pretreatment PD-L1 CPS was significantly associated with response: ypT0 ypN0 ρ=0.073, ypT0/Tis ypN0 ρ=0.030; and ORR ρ=0.021. AUROC of pretreatment sTIL association with pCR was numerically higher than with on-treatment sTILs and PD-L1 CPS (0.69 vs 0.61 vs 0.56 for ypT0 ypN0 and 0.72 vs 0.67 vs 0.62 for ypT0/Tis ypN0). Responders had higher median pretreatment sTIL levels vs nonresponders: 45% [10, 75] vs 10% [5, 20] for pCR rate by ypT0 ypN0 and 52.5% [10, 73.8] vs 10% [5, 20] for pCR rate by ypT0/Tis ypN0; 25% [5, 70] vs 10% [6.3, 27.5] for ORR. In multivariate analysis, only pretreatment sTILs were significant for both pCR endpoints (ypT0 ypN0 ρ=0.031; ypT0/Tis ypN0 ρ=0.034). Likelihood ratio tests demonstrated that for both pCR endpoints, PD-L1 CPS (ρ=0.683 ρ=0.422) and on-treatment sTILs (ρ=0.984 ρ=0.568) did not add significantly more value to pretreatment sTILs when predicting pCR.

Conclusions: Higher quantities of pretreatment sTILs and PD-L1 CPS and on-treatment sTILs were significantly associated with higher pCR rates and ORR in primary TNBC treated with pembro and NAT.
DYRK2 is a novel therapeutic target in ER negative breast cancer

Joanne Edwards¹, Gregg Baillie¹, Jean Quinn¹, Rita Monreno², Sourav Banerjee³, Nicholas Tomkinson⁴, Simon MacKay⁴ and Laureano De La Vega². ¹University of Glasgow, Glasgow, United Kingdom; ²University of Dundee, Dundee, United Kingdom; ³University of California San Diego, La Jolla, CA and ⁴University of Strathclyde, Glasgow, United Kingdom.

Background
Dual specificity tyrosine-phosphorylation-regulated kinase 2 (DYRK2) belongs to a family of CMGC kinases that function as modulators of different downstream pathways that allow cells to cope with hypoxia, DNA damage and various stress signals. Additionally, DYRK2 has been implicated in various human cancers with both pro- and anti-tumour roles, which are probably cancer type- and cell type-dependent. Furthermore, studies show that DYRK2 is involved in epithelial-mesenchymal transition, hence suggesting a role in tumour metastasis. The current study investigates the prognostic role of DYRK2 in breast cancer and investigates its potential as a novel therapeutic target.

Methods
Immunohistochemistry was employed to investigate if nuclear expression of DYRK2 was associated with clinical outcome measures in a cohort of 715 patients. Expression was determined using the weighted histoscore method. Antibody specificity was confirmed in paraffin embedded cell pellets +/- DYRK2 silencing. Cell counts in parental and CRISPR-mediated DYRK2 knocked-out MDA-MB-468 and MDA-MB-231 cells (ER, PR, HER2, AR negative) were measured using Alamar Blue; NSG™mice (n=8) were injected subcutaneously with MDA-MDB-231 with or without DYRK2 depletion to assess tumour growth in vivo.

Results
In a cohort of 715 patients, median follow-up was 160 months with 155 breast cancer deaths and 135 deaths due to other causes. The majority of patients were over 50 years of age (71%), had ductal carcinoma (88%), tumours <20mm in size (56%) and node negative disease (57%). 489 patients had ER positive disease, 226 had ER negative disease and of these 148 had TN (triple-negative) disease. DYRK2 expression was observed in the cell cytoplasm and nucleus and ranged from 3 to 200 weighted histoscore units (WHS) and ROC analysis was used to determine cut-offs, tumours with a cytoplasmic and nuclear WHS <145 were classified as low expression and tumours with a cytoplasmic and nuclear WHS >145 were classified as high expression. In the full cohort (p=0.087) and ER negative (p=0.066) cohort DYRK2 was not associated with cancer specific survival. However in TN disease high DYRK2 expression was associated with cancer specific survival (p=0.012, mean survival 145 months versus 107 months). This was potentiated in patients with ER, PR, HER2, AR negative disease (p=0.005, mean survival 166 months versus 100 months) and independent in multivariate analysis with age, histological tumour type, tumour size tumour grad, nodal status, ki67 index, chemotherapy, radiotherapy and recurrence (p=0.13, HR 3.920). Following this observation, patients with ER, AR negative disease were investigated and again high DYRK2 expression was associated with cancer specific survival (p=0.0003, mean survival 163 months versus 86 months) and was independent when combined in multivariate analysis (p=0.001, HR 4.154). To investigate if DYRK2 was a potential target in TN breast cancer, the effect of silencing DYRK2 was investigated. CRISPR-mediated DYRK2 depletion impeded cell proliferation in TN cell-lines and markedly reduced tumour burden in mouse MDA-MDB-231 xenografts (p<0.0001).

Conclusions
Our studies indicate that DYRK2 is indeed a potential therapeutic target for patients with TN breast cancer or ER, AR negative breast cancer.
Clinical implications of 63-gene signature associated with response to PARP inhibition in triple-negative and luminal B breast cancer

Michèle Beniey¹,²,³, François Marois², Takrima Haque² and Saima Hassan¹,²,³. ¹Division of Surgical Oncology, Montreal, QC, Canada; ²Centre de Recherche du Centre Hospitalier de l’Université de Montréal, Montreal, QC, Canada and ³Université de Montréal, Montreal, QC, Canada.

Background: Two recent randomized phase 3 trials have demonstrated that treatment with PARP inhibitors results in an improvement in progression-free survival (PFS) in metastatic, BRCA-mutant, HER2-negative breast cancer patients. We have previously identified a pathway-enriched 63-gene expression signature predictive of response to olaparib in seven patient-derived xenograft breast tumors, with a high overall accuracy of 86%. We found that the prevalence of our gene signature was 45% in a cohort of triple-negative breast cancer (TNBC) patients. We wanted to better understand if there were correlations between our 63-gene signature and other known prognostic markers and to determine the prognostic significance of our mutational gene signature in different PAM50 breast cancer subtypes.

Methods: We used a publicly available dataset from the NCI GDC Data Portal of TNBC patients (n = 82) to undertake clinico-pathological correlations with our 63-gene expression signature. We correlated the presence or absence of the signature with age, tumor size, lymph node status, and stage using chi² analysis, in addition to overall survival (OS) and PFS with STATA SE. We also correlated our gene signature with known TNBC subtypes from TNBCtype. Using the METABRIC cohort (n = 2509), we looked at the mutational frequency of our gene set in cBioPortal in different breast cancer subtypes and determined the prognostic value in each subtype.

Results: We did not find any statistically significant correlations between the 63-gene expression signature and age, tumor size, lymph node status, or stage amongst the 82 TNBC patients. All TNBC subtypes including 2 basal-like, immunomodulatory, low androgen receptor, 2 mesenchymal-based, and unspecified were identified in both gene-signature predicted sensitive and resistant groups, but there were no statistically significant differences between groups. The median follow-up of the TNBC cohort was 24 months, and no statistically significant associations were identified with OS or PFS. In the METABRIC cohort, the mutational frequency of any of the 63 genes for the following subgroups was identified: basal (n = 209), 85.2%; HER2+ (n = 224), 68.8%; claudin-low (n = 218), 48.2%; luminal B (n=475), 25.1%; and luminal A (n=700), 12.7%. The median follow-up of the METABRIC cohort was 127 months. We found that patients with a mutation in any of the 63 genes demonstrated a poorer overall survival, 122.8 months, in comparison to patients without any mutation, 164.6 months (P = 0.0002). In particular, luminal B patients with a mutation in any of these genes demonstrated a poorer overall survival, 90.0 months, in comparison to patients without a mutation, 132.1 months (P = 0.009). No statistically significant difference in overall survival was observed for patients with or without any mutation amongst the luminal A subtype (P = 0.26).

Conclusion: We found that patients with a mutation from our 63-gene set demonstrated a worse prognosis in comparison to patients without a mutation amongst the luminal B subtype. This is suggestive that there may be a role for our 63-gene signature to select patients amongst the luminal B subtype who may benefit from PARP inhibition.
ERBB2 copy number analysis of invasive breast carcinoma using digital droplet PCR and targeted next-generation sequencing: A focus on 'non-classical' HER2 FISH groups using the 2018 ASCO/CAP HER2 testing guideline

Soo-Ryum Yang1, Yosr Bouhlal2, Francisco M De La Vega1,2, Morgan Ballard1, Robert B West1, Richard K Sibley1, Calvin J Kuo1, Anna Vilborg2 and Kimberly H Allison1. 1Stanford University School of Medicine, Stanford, CA and 2TOMA Biosciences, Foster City, CA.

Background: Non-classical HER2 FISH results were recently reclassified in the 2018 HER2 guidelines update, and concurrent IHC testing was recommended as part of additional workup to determine the final HER2 status in these groups. In this study, we explored the genomic landscape of HER2 FISH groups using digital droplet PCR (ddPCR) and targeted next-generation sequencing (NGS) on invasive breast carcinomas.

Methods: Fifty-one clinical samples with HER2 FISH and IHC results were included in our analysis and classified into FISH groups based on the updated 2018 ASCO/CAP HER2 testing guideline: (i) Group 1A with ratio ≥2 and signals/cell ≥6, (ii) Group 1B with ratio ≥2 and signals/cell ≥4 and <6, (iii) Group 2 with ratio ≥2 and signals/cell <4, (iv) Group 3 with ratio <2 and signals/cell ≥6, (v) Group 4 with ratio <2 and signals/cell ≥4 and <6, and (vi) Group 5 with ratio <2 and signals/cell <4. Formalin-fixed paraffin-embedded samples were analyzed using two ddPCR assays each targeting an exon in the ERBB2 tyrosine kinase domain (exon 19 and 21, respectively) and a 130-gene NGS-based assay. For ddPCR, ERBB2 amplification status was determined from ddPCR ratios by using a recently published algorithm (Otsuji et al. 2017). For targeted NGS, ERBB2 amplification was called when copy number gains were detected in the majority of exons in ERBB2 (>50% of exons).

Results: Mean ddPCR ratios varied amongst the different FISH groups (P < 0.0001). As expected, patients with Group 1A had the highest mean ddPCR ratios compared to those with other FISH findings (P < 0.0001). Furthermore, there was a correlation between ERBB2 ddPCR ratios and HER2 FISH ratios (ρe19 = 0.4435, P = 0.001 and ρe21 = 0.4644, P = 0.0006). Using ddPCR, ERBB2 amplifications were detected in all classically amplified Group 1A cases (5/5) and in none of the classically non-amplified Group 5 cases (0/12). Interestingly, ddPCR assays called ERBB2 amplification in four cases with non-classical results: one in Group 2 (1/6), two in Group 3 (2/6), and one in Group 4 (1/17), including two cases in Groups 3 and 4 which also showed concomitant HER2 overexpression by IHC (3+). Similarly, targeted NGS revealed ERBB2 amplification in all Group 1A cases (5/5) and in none of the classically non-amplified Group 5 cases (0/12). Furthermore, NGS detected amplification in three non-classical cases: one in Group 1B (1/5), one in Group 3 (1/6), and one in Group 4 (1/17), including one case in Group 1B which was not called amplified by ddPCR. Notably, the three cases with amplification by NGS were the only three cases in the non-classical groups with HER2 overexpression by IHC. Overall, there was a strong concordance between ERBB2 amplification status by ddPCR/NGS and HER2 overexpression by IHC (κe19 = 0.79, κe21 = 0.92, κNGS = 1.0).

Conclusion: ERBB2 amplification using ddPCR and NGS is correlated with HER2 overexpression in both classical and non-classical FISH groups, thus providing genomic evidence to support the recent recommendation for concurrent IHC testing in cases with unusual FISH results. Our findings also highlight a potential role of ddPCR and targeted NGS in the workup of challenging HER2 cases.
Dual targeting of androgen receptor and IKK alpha is a potential therapeutic strategy for triple negative breast cancer

Antonia K Roseweir¹, Phungern Khongthong¹, Katie Dickson¹, Lindsay Bennett¹ and Joanne Edwards¹. ¹University of Glasgow, Glasgow, United Kingdom.

**Background**
There are limited treatments for triple negative breast cancer (TNBC) patients and an unmet need for targeted approaches in these patients. In the last 4-5 years, the prevalence of high androgen receptor (AR) expression in TNBCs has been noted in up to 50% of tumors suggesting it has clinical relevance. The non-canonical NF-kB pathway is also upregulated in this patient group and it has been reported that that there is crosstalk between these pathways. Therefore the aim of this study was to examine the expression of IKKα and AR in breast cancer tissue samples, to assess if combining these markers increased prognostic power.

**Methods**
Immunohistochemistry was performed on tissue microarray of 410 patients to assess proteins level of IKK alpha and AR. Protein expression levels were assessed using the weighted histoscore (WHS) method. The median was employed as the cut off for IKK alpha and 1% as cut off for AR. Expression was analyzed for associations with cancer-specific survival (CSS) and recurrence-free survival (RFS).

**Results**
In a cohort of 370 breast cancers nether AR nor IKK alpha alone or combined were associated with CSS or RFS. Stratifying patients by ER status did not impact CSS or RFS. However, in TNBC patients (n=82) high expression of AR was associated with shorter CSS (HR 2.55 95 CI 1.61-5.59, p=0.013). To assess if combining AR and IKK alpha increased prognostic power, AR and IKK alpha were combined into a single score: 0= low expression of both or high expression of one and 1= high expression of both. In the full cohort or when stratified by ER status the score was not associated with CSS or RFS, however in TNBC the combined score potentiated the effect observed with AR alone, (HR 1.68 95 CI 1.20-2.33, p=0.001). Patient CSS was stratified from 11.5 years to 4.6 years and was independently associated with CSS when compared with common clinicopathological factors (HR 1.56 95CI 1.11-2.21, p=0.011). In addition, the combined score was associated with decrease radiotherapy use (p=0.032), increased recurrence rate (p=0.014), decreased cytotoxic T cells (p=0.007), B cells (p=0.043) and macrophages (p=0.037).

**Conclusions**
A combined AR and IKK alpha score is an independent prognostic classification for patients with TNBC. Patients with high expression of both AR and IKK alpha a significantly reduced survival and were immune cell cold. This study suggests that this patient group will not benefit from immunotherapy but dual targeting with anti-androgens and IKK alpha selective inhibitors could offer a novel therapeutic strategy for this patient group.
LIV-1 expression in primary breast cancers in the I-SPY 2 TRIAL

Christina Yau1, Lamorna Brown-Swigart1, Smita Asare2, I-SPY 2 TRIAL Consortium2, Laura Esserman1, Laura van’t Veer1, Heather Beckwith3, Andres Forero4 and Hope Rugo1. 1University of California, San Francisco, San Francisco, CA; 2QuantumLeap Healthcare Collaborative, San Francisco, CA; 3University of Minnesota, Minneapolis, MN and 4University of Alabama, Birmingham, AL.

Background: LIV-1 is an estrogen-inducible gene that has been implicated in epidermal-to-mesenchymal transition (EMT) in preclinical models of progression and metastasis. Its expression is associated with node-positivity in breast cancer; and has been detected in a variety of cancer types, including estrogen receptor positive breast cancers. SGN-LIV1A is a novel antibody drug conjugate targeting LIV-1 that is currently being evaluated in the I-SPY 2 TRIAL. In this pilot study, we evaluated LIV-1 levels by IHC within HR/HER2/MammaPrint (MP) defined subtypes among patients screening for the I-SPY 2 TRIAL and its correlation to microarray assessed LIV-1 expression levels.

Method: In a pilot study, LIV-1 IHC staining was performed by Quest Diagnostics on the pre-treatment samples of 38 patients screening for the I-SPY 2 TRIAL. Pre-treatment expression data generated on a custom Agilent 44K platform was also available. We summarized the LIV-1 H-Scores and percent (%)-positivity across the population and within HR/HER2/MP subtypes; and we assessed the Pearson correlation between LIV-1 H-Score and LIV-1 gene expression levels. In addition, we compared the pre-treatment LIV-1 expression levels within HR/HER2/MP subtypes across I-SPY 2 TRIAL patients from completed arms and their relevant controls (n=989) using ANOVA and post-hoc Tukey tests. Our statistics are descriptive rather than inferential; and does not take into account multiplicities of other biomarkers outside of this study.

Results: Of the 38 patients evaluated, 37 have LIV-1 %-positivity > 0; and 18 (47%) have 100% LIV1 positivity. The median LIV-1 H-Score is 200; and 89% of patients (34/38) have moderate/high LIV-1 staining (with H-Score≥100). Of the 34 patients who proceeded onto the trial (and have known HR/HER2/MP status), 9 are triple negative, 19 are HR+HER2-, and 6 are HER2+. Due to our small sample size, we did not further subset the triple negative and HER2+ cases; but within the HR+HER2- patients, 10 are MP1 compared to 9 who are MP2 class. LIV1 H-Score appears highest within the HR+HER2-MP1 cases (median: 290), followed by the HER2+ (median: 216), then the HR+HER2-/MP2 (median: 155), and the TN (median: 120) subtype. LIV1 H-score is significantly correlated with LIV-1 mRNA expression levels (Rp=0.79, p<0.0001). Consistent with these observations, LIV-1 pre-treatment expression levels are significantly higher in the HR+HER2-MP1 group relative to all other HR/HER2/MP defined subtypes (Tukey HSD p < 0.0001) across the I-SPY 2 TRIAL population. The HR+HER2+MP1 group also have high LIV-1 expression levels.

Conclusion: Our result suggest that although LIV-1 expression differs by subtype, it is expressed at a moderate/high level in the majority of patients. The good correlation between IHC and array-based LIV-1 expression levels enables us to leverage the entire existing I-SPY 2 dataset and confirm the high rates of LIV-1 expression across the I-SPY 2 population. Further studies to evaluate LIV-1 expression as a biomarker of response to LIV-1 targeting therapies for the neoadjuvant treatment of breast cancer are warranted and ongoing in I-SPY 2.
Evaluating contribution of hyperactive c-Met and ErbB signaling to tumor progression in mouse breast tumor xenografts: An in vivo study of c-Met and ErbB targeted therapies

Lance G Laing¹, David J Burns¹, Salmaan Khan¹, Ian A MacNeil¹, Benjamin E Rich¹, Samanatha M Kharbush¹, Sajjaad M Soltani¹ and Brian F Sullivan¹. ¹Celcuity Inc., Minneapolis, MN.

Background: Hyperactive c-Met signaling, including cross-talk between c-Met and ErbB family receptors, is suspected of contributing to tumor progression in a variety of cancer types. Clinical trials evaluating c-Met inhibitors alone and in combination with other targeted therapies, have produced mostly negative results in patients with amplified c-Met. This suggests other biological factors, such as c-Met and ErbB signaling activity, may be important to measure when identifying patients eligible for c-Met therapies. To measure the c-Met and ErbB signaling activity of a patient's live tumor cells, a new assay using an impedance biosensor, the CELx multi-pathway signaling function (CELx MP) test, was developed. The CELx MP test measures a patient's ex vivo live tumor cell response in real-time to specific ErbB and c-Met agonists to diagnose breast cancer tumors with hyperactive HER1, HER2, HER3, HER4, and c-MET signaling activity. In this study, to further elucidate the role of c-Met signaling and its potential involvement with ErbB signaling as a cancer driver, we studied in vivo response to a c-Met inhibitor (tepotinib), an EGFR inhibitor (erlotinib), a pan-HER inhibitor (neratinib), and a combination of these therapies using breast tumor xenograft models.

Methods: HCC1954, a HER2+ cell line with hyperactive c-Met and EGFR signaling and normal HER3 and HER2-driven signaling, according to the CELx MP test, was studied. Sixty 4-5-week-old female NSG mice were injected with two million cells. Mice were randomly assigned to either a control group that received Captisol or one of five treatment groups that received either neratinib, tepotinib, erlotinib, erlotinib and tepotinib, or neratinib and tepotinib for 17 days.

Results: The most effective treatment was the combination of neratinib plus tepotinib, where the average tumor size reduction relative to the control group was 71% (p=0.0003). The average tumor size in the neratinib plus tepotinib treated group was 37% smaller (p=0.049) than the neratinib treated group, and 67% smaller (p=0.0026) than the tepotinib treated group. In the erlotinib plus tepotinib treatment group, the average tumor size was 51% smaller than the control group tumors, but the difference was not statistically significant (p=0.11). No significant difference in tumor size was found between the control group and the erlotinib or tepotinib treated groups.

Conclusions: The results demonstrate that hyperactive and coincident c-Met and EGFR signaling contributes to the progression of certain breast cancers. This breast cancer sub-type is more responsive to treatment with a c-Met inhibitor plus a pan-HER inhibitor than a c-Met inhibitor plus an EGFR inhibitor or any of the single agents studied. This suggests that when hyperactive c-Met signaling and a hyperactive ErbB family member is present in a patient's tumor, each of the ErbB pathways as well as the c-Met pathway must be inhibited to treat the tumor most effectively. These findings provide strong evidence that HER2-negative breast cancer patients with coincident hyperactive c-MET and ErbB signaling may respond to treatment with a combination of pan-HER and c-Met inhibitors.
Predicting pathological complete response by the combination of microRNAs in patients with HER2-positive primary breast cancer who received neoadjuvant combination therapy of trastuzumab, lapatinib and paclitaxel: Results from JBCRG-16 (NeoLath) study

Akihiko Shimomura¹, Norikazu Masuda², Junpei Kawauchi³, Satoko Takizawa³, Makiko Ichikawa³, Juntaro Matasuzaki⁴, Katsumasa Kuroi⁵, Hisato Harano⁶, Naohito Yamamoto⁷, Kenichi Inoue⁸, Nobuyasu Suguromi⁹, Kenjiro Aogi⁴, Shinji Ohno¹¹, Kenji Tamura¹, Takahiro Ochiya¹ and Masakazu Toi¹¹. ¹National Cancer Center Hospital, Tokyo, Japan; ²NHO Osaka National Hospital, Osaka, Japan; ³Tray Industries, Inc., Kamakura, Japan; ⁴National Cancer Center Research Institute, Tokyo, Japan; ⁵Tokyo Metropolitan Komagome Hospital, Toyko, Japan; ⁶Tsukuba University Hospital, Tsukuba, Japan; ⁷Chiba Cancer Center, Chiba, Japan; ⁸Saitama Cancer Center, Saitama, Japan; ⁹Kanagawa Cancer Center, Kanagawa, Japan; ¹⁰NHO Shikoku Cancer Center, Matsuyama, Japan; ¹¹Cancer Institute Hospital, Tokyo, Japan and ¹²Kyoto University Hospital, Kyoto, Japan.

[Background] JBCRG-16 (NeoLath) study is a five-arm study to evaluate the efficacy and safety of lapatinib and trastuzumab (6 weeks) followed by lapatinib and trastuzumab plus weekly paclitaxel (12 weeks) with/without prolongation of anti-HER2 therapy prior to chemotherapy (18 vs. 6 weeks), and with/without endocrine therapy in patients with HER2+ and/or estrogen receptor (ER)+ disease. The primary endpoint was pathological complete response (pCR) rate and pCR rate was 47.9% (Masuda N, et al. Breast Cancer, 2018). It is recently reported that microRNAs (miRNAs) are stably present in serum and potentially useful in the diagnosis and evaluation of treatment of cancer. We performed exploratory analysis of detecting pCR by comprehensive analysis of serum miRNAs.

[Materials and Methods] Serum samples were obtained from study participants who received neoadjuvant systemic therapy with trastuzumab, lapatinib and paclitaxel. Before profiling of miRNAs, the overall serum samples were randomly divided into two sets, namely the training set and the testing set with pCR or non-pCR. Pathological complete response (pCR) was defined as the absence of residual invasive cancer of the resected breast specimen and all sampled regional lymph nodes. Total RNA was extracted from a 300 µl serum sample using 3D-Gene® RNA extraction reagent from a liquid sample kit. A comprehensive quantitative expression analysis of miRNA was performed using the by DNA chip 3D-Gene®, which was designed to detect 2565 miRNA sequences registered in miRBase release 21 (http://www.mirbase.org/). The expression level of miRNAs were normalized by internal control (miR-2861, miR-149-3p and miR-4463). Clinicopathological data was retrieved from trial data.

[Results] A total of 112 samples were obtained. Seventy were used in the training set and others were used in the testing set. Median age was 54 years (range 26-70). Sixty-five (58%) patients were pre-menopausal. ER was positive in 59 patients (52.7%). Fourteen (12.5%) were T1c, 78 (69.6%) were T2 and 20 (17.9%) were T3. Fifty-seven (50.9%) patients were node-positive. Fiftynine (52.7%) patients achieved pCR. The formula with the combination of three miRNAs (miR-A, miR-B, miR-C) was found to be able to predict pCR. This set had a sensitivity of 62.5%, specificity of 86.7% and accuracy of 71.8% in the testing cohort. Area under curve of receiver operating characteristic curve was 0.753.

[Conclusion] The combination of three miRNAs has potential to predict pCR in patients who received neoadjuvant combination therapy of trastuzumab, lapatinib and paclitaxel in HER2-positive primary breast cancer. The further analysis of changing expression of miRNAs during neoadjuvant therapy is underway and further results will be presented in the symposium.
mRNA expression of HER2 by PCR as a strong predictor of pathologic response to neoadjuvant antiHER2 therapy

Ariadna Gasol Cudós, Serafin Morales Murillo, Joel Veas Rodríguez, Ana Velasco Sánchez, Anna Serrate López, Jordi Melé Olivé and Carles Canosa Morales. 1 Hospital Universitari Arnau de Vilanova de Lleida, Lleida, Spain.

Background: Pathologic response to neoadjuvant therapy is the most important prognostic factor so new agents should aim to improve it. HER2 expression in breast cancer provides prognostic and predictive information of response to antiHER2 therapy. The quantification of HER2 expression by mRNA is one of the most potent markers of cellular dependence to HER2 pathway.

Methods: From a series of 160 patients with early or locally advanced HER2 positive breast cancer who received neoadjuvant treatment with chemotherapy and antiHER2 drugs, mRNA expression of HER2 was analyzed in 69 specimens and it was correlated to pathologic complete response (pCR).

Results: Median age was of 52.5 years (29-86), tumor size of 33mm (10-111), 39 (53%) patients had nodal involvement. Median ki67 expression was of 45% (17-80), 28 (38%) tumors were estrogen receptor (ER) positive and 46 (62%) negative. We also analyze the expression of tumor-infiltrating-lymphocytes (TILs) by immunohistochemistry in 43 samples because their expression is also a strong predictive of pathologic response. A total of 31/69 patients (45%) achieved a pCR with a median of mRNA expression of 7,55 (3,8 – 11) in comparison with 2.03 (1,2 -2,8) in patients without pCR (p: 0,002). In the univariable analysis, variables correlated to pCR were estrogen receptor=0 (OR 0,186 IC 95% 0,063-0,549, p: 0,002), mRNA (OR 5,689 IC 95% 1,854-17,452, p: 0,002) and TILs (OR 15,167 IC 95% 3,223-71,38, p: 0,001) and in the multivariable analysis, TILs and mRNA expression were found to be independent predictive factors for pCR. The quantification of HER2 by mRNA obtained an impressive response specially in ER negative patients with a rate of pCR of 100% in samples of mRNA expression upper of 3,6 and ER negative. However, patients with mRNA expression lower than 3,6 with a pCR rate of 32%, could reach to an 80% rate if they had high TILs expression.

Conclusions: Quantification of HER2 expression by mRNA is a strong predictive factor of pCR (OR 5,689); achieving a 100% pCR in ER negative tumors. TILs are also a predictive factor for pCR (OR 15,167) and its combination with mRNA expression could improve pCR rates; thus, patients with mRNA expression lower than 3,6, if they had a higher TILs expression could reach to an 80% pCR.
Elucidating the role of functional signal transduction pathway activity in sensitivity and response of triple negative breast cancer to PI3K inhibition

Zhanfang Guo¹, Wim Verhaegh², Jeremy Hoog¹, Sandeep Rajput¹, Dianne van Strijp², Anja van de Stolpe², Shunqiang Li¹ and Cynthia Ma¹. ¹Washington University School of Medicine, St. Louis, MO and ²Philips Research, Eindhoven, Netherlands.

Introduction
The PI3K signaling pathway is frequently active in triple negative breast cancer (TNBC), but response to PI3K inhibition is still poorly understood. To gain insights in therapy response and resistance, it is important not only to assess genetic alterations of these tumors, but also their phenotypic characteristics. Furthermore, not only is the functional status of the PI3K pathway important to know, but also other signal transduction pathways that may drive tumor growth, as they may explain primary or acquired therapy resistance.

Material & Method
We analyzed 17 patient derived xenograft (PDX) models of TNBC with varying response to buparlisib treatment. Long-term response (~30 days) was assessed by comparing growth rates between buparlisib and vehicle treated PDXs. For characterization, mRNA expression analysis was performed on tumor material post 3 days of vehicle or buparlisib treatment of each PDX model. Functional pathway activity was determined using computational Bayesian networks that look at mRNA levels of pathway target genes resulting from activation (Verhaegh et al, Cancer Res 2014), amongst others for the FOXO-PI3K (van Ooijen et al, Am J Pathol, in press), ER, AR, Hedgehog, TGFbeta and Wnt pathways. These computational networks were calibrated on samples with known pathway activity, and biologically validated on various healthy and diseased cell and tissue types.

Results
On an initial set of 6 PDX models, pathway activity clearly varied between different TNBC PDXs, and between vehicle and buparlisib treatment. ER pathway activity was low in all samples, as expected in TNBC. Two PDX models with the most growth reduction by buparlisib showed high PI3K activity, of which one based on low FOXO activity and the other on oxidative stress. The former, best responding PDX showed a clear reduction in PI3K activity (restoring FOXO activity), when comparing 3 days buparlisib to vehicle treatment. Of the two PDX models with least growth reduction, one had low PI3K activity, while the other one, carrying a PIK3CA mutation, did show high PI3K activity (low FOXO), but this remained after treatment. Other differences in pathway activity that were found, included slightly elevated AR and Wnt activity in one PDX with good response, and somewhat higher TGFbeta activity in four PDXs (good, medium and poor response). Analysis of the remaining 11 PDXs is ongoing, including other signal transduction pathways, to investigate the variation in pathway activity across the entire panel and to shed more light on the differences in tumor biology between the PDX models.

Conclusion
Our computational Bayesian networks measured differences in functional activity of signal transduction pathways across a collection of TNBC PDX models, which may be expected due to the large variation between TNBC tumors. Functional PI3K activity was related to growth inhibition by buparlisib treatment, and reduction of PI3K pathway activity was observed upon treatment in responding PDX models. Other pathways also showed variation across PDXs. Further clinical evaluation of our signal transduction pathway activity measurement is ongoing. RT-qPCR based analysis is available, optimized for FFPE tissue and small samples.
Significance of baseline neutrophil-to-lymphocyte ratio for progression-free survival of patients with HER2-positive locally advanced and metastatic breast cancer treated with trastuzumab emtansine

Michiko Imamura\(^1\), Takashi Morimoto\(^2\), Chiyomi Egawa\(^3\), Yoshimasa Miyagawa\(^1\) and Yasuo Miyoshi\(^1\). \(^1\)Hyogo College of Medicine, Nishinomiya, Japan; \(^2\)Yao Municipal Hospital, Yao, Japan and \(^3\)Kansai Hosai Hospital, Nishinomiya, Japan.

**Purpose** The prognosis of human epidermal growth factor receptor 2 (HER2)-positive locally advanced or metastatic breast cancers (MBCs) has dramatically improved due to the introduction of trastuzumab, pertuzumab, and trastuzumab emtansine (T-DM1). The efficacy of T-DM1 is prolonged for some patients; however, the predictive factors remain unknown. There is a report that T-DM1 induced antitumor immunity in patients treated with neoadjuvant therapy, with tumor infiltrating lymphocytes (TILs) increasing after the administration of T-DM1. Based on these observations, the benefits of T-DM1 for prognosis may be mediated by an immune reaction against breast cancers, at least in part. As an indicator of cancer immunity, in addition to TILs, the neutrophil-to-lymphocyte ratio (NLR) has been established in early breast cancers. In the present study, we investigated the usefulness of the NLR for treatment efficacy of T-DM1 in HER2-positive MBCs. **Methods** Fifty-three advanced or metastatic breast cancers treated with T-DM1 were retrospectively recruited from three institutes. The NLR in the peripheral blood was measured at baseline (just before the start of T-DM1) and after one cycle (just before the start of cycle 2). The cutoff value of the NLR was set at 2.56 (median value) and progression-free survival (PFS) and overall survival (OS) according to NLR levels were evaluated. **Results** The PFS of patients with NLR-low at baseline (NLR<2.56; \(n=26\); median, not reached) was significantly better than that of patients with NLR-high (NLR\(\geq\)2.56; \(n=27\); median, 4.13 months; hazard ratio [HR], 0.226; 95% confidence interval [CI], 0.112-0.493; \(p=0.0001\)). There was a significant association between improved OS and a low NLR (HR, 0.384; 95% CI, 0.170-0.910; \(p=0.0296\)). In the subgroup analysis, patients with NLR-low consistently had improved PFS compared to those with NLR-high irrespective of the number of prior chemotherapy regimens, prior trastuzumab use, visceral metastasis, estrogen receptor status, and HER2 immunohistochemical staining score. According to univariable analysis of each clinical and biological factor for PFS, the NLR-low group was solely and significantly associated with favorable PFS compared with the NLR-high group (HR, 0.226; 95% CI, 0.112-0.493; \(p=0.0001\)). The NLR at baseline was significantly increased after one cycle treatment (\(p=0.0005\)). Interestingly, the PFS of patients whose NLR was high at baseline but changed to low after one cycle (\(n=12\); median PFS, 6.47 months) was better than that of patients with a consistently high NLR (\(n=14\); median PFS, 3.27 months). **Conclusion and Discussion** A low baseline NLR was found to be significantly associated with improved PFS for patients treated with T-DM1. Interestingly, lymphocyte count was significantly increased in patients in the NLR-low group but not in the NLR-high group after one cycle treatment. Although detailed mechanisms remain unknown, the treatment efficacy of T-DM1 may be partly mediated by immunoreaction on the basis of present data. A low baseline NLR appears to be beneficial for treatment with T-DM1 in HER2-positive breast cancers.
Sub-group of HER2- breast cancer patients with hyperactive and co-involved c-Met and ErbB pathways identified: Functional signal profiling test identifies patient group that may benefit from c-Met and pan-HER combination therapy

Lance G Laing¹, David J Burns¹, Salmaan Khan¹, Ian A MacNeil¹, Benjamin E Rich¹, Samantha M Kharbush¹, Sajjaad M Soltani¹ and Brian F Sullivan¹. ¹Celcuity Inc., Minneapolis, MN.

**Background:** Biological factors other than c-Met status, such as c-Met and ErbB signaling activity, may be important to measure when identifying patients eligible for c-Met therapies. A new assay using an impedance biosensor was developed to measure c-Met and ErbB signaling activity of live tumor cells. The CELx Multi-Pathway Signaling Function (CELx MP) Test measures an individual patient's *ex vivo* live tumor cell response in real-time to specific ErbB and c-Met agonists and antagonists to diagnose breast tumors with hyperactive HER1, HER2, HER3, and c-MET signaling. This study set out to: 1) determine the prevalence of hyperactive c-Met and ErbB family signaling amongst HER2- breast cancer patients; and 2) characterize potential cross-talk between c-Met and ErbB pathways.

**Methods:** For the prevalence study, fresh breast tumor specimens were obtained from 74 HER2- breast cancer patients. The amount of HER1, HER2, HER3, and c-Met for each specimen was determined using FACS. Real-time live cell response to specific ErbB and c-Met agonists (NRG1b, EGF, or HGF) alone and in combination, with or without ErbB and c-Met antagonists (2C4, a HER2 mAb dimerization inhibitor, tepotinib, a c-Met TKI, or neratinib, a pan-HER TKI) was measured using an xCELLigence RTCA impedance biosensor. From these responses, HER1, HER3, and c-Met signaling initiated by their respective agonists was quantified. The net amount of HER2 participation in EGF and NRG signaling was also quantified. Signaling activity above a previously determined cutpoint was used to identify abnormal levels of HER1, HER2, HER3 and c-Met signaling activity. For the cross-talk study, three primary HER2- breast cancer specimens with hyperactive c-Met and ErbB signaling were obtained. Response to HGF, EGF, and NRG1 alone, with or without tepotinib, was measured for these specimens using an impedance biosensor.

**Results:** The FACS analysis found all 74 tumor samples had normally expressed amounts of HER1, HER2, HER3, and c-Met. Of these samples, 20 of 74 (27.0%; 95% CI=18%-38%) had hyperactive c-Met signaling coincident with hyperactive signaling from at least one ErbB pathway. In each patient sample, neratinib combined with tepotinib inhibited virtually all signaling activity initiated with a combination EGF, NRG1 and HGF. In the cross-talk analysis of the three tumor samples, signaling response to EGF or NRG1 when combined with a c-Met antagonist was 9%-98% higher than signaling response measured with EGF or NRG1 alone.

**Conclusions:** This test found a significant sub-set of HER2- breast cancer patients with coincidental hyperactive c-Met and ErbB signaling tumors that respond *ex vivo* to a combination of pan-HER and c-Met TKI's. The unexpected increase in EGF and NRG1 signaling in the presence of a c-Met antagonist provides strong evidence that c-Met and ErbB signaling is co-involved and may explain why a c-Met TKI is not an effective antagonistic when c-Met is hyperactive for this patient sub-set. A clinical trial to evaluate treatment response of this patient sub-set to combined c-Met and pan-HER inhibitors is warranted.
MARCKS phosphorylation contributes to the aggressive behavior in inflammatory breast cancer

Maroua MaM Manai1,5,6,7, Jeanne JTP Thomassin-Piana2, Pascal PF Finetti1, Amor AG Gammoudi6, Mohamed MM Manai7, Khaled KR Rahal6, Daniel DB Birnbaum1, Hamouda HB Boussen5,7 and François FB Bertucci1,3,4. 1Centre de Recherche en Cancérologie de Marseille; INSERM UMR1068; IFR137, Aix Marseille Université, Marseille, Bouche du Rhône, France; 2Institut Paoli-Calmettes, Marseille, France. 3UFR de Médecine, Aix Marseille Université, Marseille, Bouche du Rhône, France; 4UFR de Médecine, Aix Marseille Université, Marseille, Bouche du Rhône, France; 5Laboratoire de Biochimie et Biologie Moléculaire, Faculté des Sciences de Tunis, Université de Tunis El Manar, Tunis, Tunisia; 6Institut Salah Azaiez, Tunis, Tunisia and 7Service d’Oncologie Médicale, Hôpital l’Ariana, Ariana, Tunisia.

Background: Inflammatory breast cancer (IBC) is the most aggressive form of locally-advanced breast cancer. Despite multimodality treatment, the 5-year survival remains around 50%. Identification of new therapeutic targets is crucial. We previously reported MARCKS mRNA and protein overexpression in IBC in the largest transcriptomics and immunohistochemistry (IHC) study reported to date (1,2). Here, we evaluated phospho-MARCKS (p-MARCKS) protein expression in IBC and non-IBC clinical samples.

Patients and methods: Using IHC analysis, we retrospectively evaluated the p-MARCKS protein expression in a series of 502 tumors (133 IBC and 369 non-IBC), from Tunisian and French patients. All samples were pre-therapeutic tumor samples. We searched for correlations between p-MARCKS expression and clinopathological features. Results: Using 1% of stained tumor cells as positivity cut-off, we demonstrated that p-MARCKS expression was more frequently positive in IBC than in non-IBC (p=2.8E-11). The percentage of p-MARCKS-positive cases was 47% in IBC versus 14% in non-IBC, and was not different between the Tunisian and French IBC samples (48 versus 46%, p=1). Correlations were found between p-MARCKS expression and young age of patients in IBC vs nIBC (1.73E-06) and high grade (p=4.62E-02). In multivariate analysis integrating all significant variables, phospho-MARCKS protein expression remained associated with the IBC phenotype (p=4.7E-05).

Conclusion: Phospho-MARCKS overexpression might in part explain the poor prognosis of IBC. As an oncogene associated with unfavorable prognostic factors, phospho-MARCKS might represent a new potential therapeutic target in IBC.

Key word: Phospho-MARCKS, expression, immunohistochemistry, inflammatory breast cancer, unfavorable prognosis features.
BluePrint molecular subtyping versus HER2 assessment by immunohistochemistry and FISH in the real-world diagnostic setting

Tina Treece\textsuperscript{1}, William Audeh\textsuperscript{1}, Fernando Navarro\textsuperscript{1} and Jennifer Wei\textsuperscript{1}. \textsuperscript{1}Agendia, Inc., Irvine, CA.

**Background:** Both the Aphinity and ExteNET trials for anti-HER2 targeted agents were challenged in showing significant benefit of added HER2-targeted treatment. The findings suggested biological heterogeneity in HER2+ cancers, not entirely identified by IHC/FISH, requiring more nuanced biomarkers to clearly identify patient subsets who may derive benefit from new HER2-targeted agents. We have previously shown that BluePrint (80-gene) molecular subtyping reclassifies nearly half of HER2+/ER+ patients to Luminal-type with differential neoadjuvant treatment response (Whitworth, Ann Surg Oncol 2014; Whitworth, ASCO 2018). Here, we evaluated the reclassification rate in the real-world diagnostic setting. **Methods:** Physicians regularly provide pathology reports to Agendia, Inc for samples which are processed for MammaPrint (70-gene signature) and BluePrint molecular assays as part of routine diagnostic care. For this analysis, 4986 sequentially available pathology reports (submitted between October 2016 to October 2017) were reviewed; HER2 and ER IHC results were captured. The molecular subtype was compared to IHC/FISH status. **Results:** HER2 IHC/FISH results were available for 1568 samples. Of those, 85% (1330/1568) were HER2-nonamplified, 10% (153/1568) were HER2-equivocal, and 5% (85/1568) were HER2-amplified by IHC/FISH.

**HER2 IHC/FISH vs BluePrint Subtype**

Of the HER2-nonamplified tumors, BluePrint reclassified 0.1% (2/1330) as HER2-type. Of the HER2-equivocal tumors, none were HER2-type by BluePrint; 91% (139/153) were Luminal-type and 9% (14/153) were Basal-type. Of the HER2-amplified tumors, 15% (13/85) were dominant HER2-type, 79% (67/85) were dominant Luminal-type, and 6% (5/85) were Basal-type.

**Conclusions:** In this set of tumors identified as HER2-amplified by IHC/FISH, BluePrint reclassified 85% of tumors to non-HER2 molecular subtypes, mostly Luminal-type for ER-positive tumors and Basal-type for ER-negative tumors. Moreover, BluePrint gave clarity where IHC/FISH could not, classifying all HER2-equivocal tumors to non-HER2 subtypes. Additional therapeutic options should be explored for HER2+/ER+ BluePrint Luminal-type patients who have observed much lower pCR rates versus BluePrint HER2-type patients (12% vs. 51%, respectively; Lee, AACR 2018).
Changes in the expression of HER2 and other genes in HER2-positive metastatic breast cancer induced by treatment with ado-trastuzumab emtansine and/or pertuzumab/trastuzumab

Kumiko Kida1, Jangsoon Lee1, Huey Liu1, Bora Lim1, Rashmi K Murthy1, Aysegul A Sahin1, Debu Tripathy1 and Naoto T Ueno1.
1The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Although tremendous progress has been achieved with targeted therapy for HER2-positive (HER2+) metastatic breast cancer, most advanced tumors eventually develop resistance. Improving our understanding of mechanisms of resistance to anti-HER2 therapy is needed to develop new therapeutic approaches. The purpose of this study was to identify the mechanisms of resistance to treatment with ado-trastuzumab emtansine (T-DM1) and/or taxane/pertuzumab/trastuzumab (TPH).

Methods: In our preclinical analysis, HER2+ cell lines resistant to treatment with T-DM1 (n=5), and pertuzumab/trastuzumab (n=3) were generated. HER2 expression in the original and resistant cell lines was compared using Western blot, and HER2 gene amplification was compared in them using fluorescence in situ hybridization (FISH) and a Droplet Digital Polymerase Chain Reaction HER2 copy-number-validation assay. In our clinical analysis, nine patients with HER2+ metastatic breast cancer who had progressed on T-DM1 and/or TPH were enrolled. Patients underwent biopsies following treatment with T-DM1 and/or TPH. Targeted next-generation sequencing was performed using the FoundationOne® assay (Foundation Medicine, Inc.) to identify gene alterations. Also, the HER2 expression before and after the therapy was compared using immunohistochemistry and/or FISH.

Results: In preclinical analysis, HER2 expression/amplification by Western blot and gene copy-number analysis was significantly decreased in T-DM1–resistant cell lines (four of five cell lines; \( P < 0.01 \)) but not in pertuzumab/trastuzumab-resistant cell lines (none of three cell lines). In clinical analysis, the patients' median age was 54 years (range, 45-77 years), and five patients (56%) were ER+. Five patients (56%) received first-line anti-HER2 therapy, and four patients (44%) received two lines of anti-HER2 therapy prior to enrollment. We observed loss of HER2 expression in four of nine patients (44%) after undergoing anti-HER2 therapy. After receiving TPH, one of eight patients (13%) lost HER2 positivity according to FISH. In contrast, after T-DM1, three of four tested patients (75%) lost HER2 amplification by FISH. As for next-generation sequencing, we analyzed seven samples: three after treatment with TPH and four after treatment with T-DM1. In four of these samples (57%), we observed loss of HER2 amplification: one after treatment with TPH and three after treatment with T-DM1. TP53 mutations were seen in all patients. Additionally, we observed TOP2A and MCL1 amplification in two patients with ERBB2 amplification and AKT1 amplification in one patient with ERBB2 amplification loss.

Conclusions: We show for the first time that T-DM1–resistant breast cancer cells lose HER2 expression and amplification. Additionally, we observed loss of HER2 expression in patient samples following treatment with HER2 targeted therapy. Further study of resistant tumor samples is required to understand the impact of HER2 loss on outcomes. For the time being, repeating biopsy analysis of a metastatic site after treatment with T-DM1 to determine the HER2 expression status is reasonable, and it may increase the efficacy of future anti-HER2 therapy.
Predicting pathological complete response (pCR) to neoadjuvant trastuzumab in patients with breast cancer using HER2 mass spectrometry

Elisa Gasparini¹, Alessandra Bisagni², Roberto Di Cicilia¹, Elisabetta Kuhn², Giuseppe Falco³, Guglielmo Ferrari³, Moira Foroni², Ione Tamagnini², Cristina Bassano², Moira Ragazzi², Giorgio Gardini², Fabiola Cecchi⁴, Todd Hembrough⁴ and Giancarlo Bisagni¹.
¹Azienda USL Reggio Emilia – IRCCS, Reggio Emilia, Italy; ²Pathology Unit, Azienda USL Reggio Emilia – IRCCS, Reggio Emilia, Italy; ³Breast Surgery, Azienda USL Reggio Emilia – IRCCS, Reggio Emilia, Italy and ⁴NantOmics, Rockville.

**Background:** Around 40% of HER2-positive (HER2+) breast cancer patients who receive trastuzumab-based neoadjuvant therapy (TNT) achieve pCR (the FDA-recommended outcome measure in this setting). The ability to predict which patients will respond to TNT could support decisions regarding selection neoadjuvant agents or combinations. We previously quantified tumor expression of HER2 with mass spectrometry in archived biopsies of breast cancer patients who received adjuvant trastuzumab; HER2 levels > 2200 amol/ug of tumor protein were associated with superior disease-free and overall survival. We hypothesized that this HER2 protein cutoff would predict pCR in a HER2+ neoadjuvant population treated with TNT.

**Methods:** Formalin-fixed, paraffin-embedded tumor biopsies from patients with breast cancer were microdissected and solubilized for proteomic profiling with multiplexed mass spectrometry. Patients were dichotomized using the pre-specified HER2 cutoff of 2200 amol/ug. Relationships between pre-treatment HER2 expression and pCR following TNT were assessed with Fisher’s exact test. Results: Of 65 evaluable patients, 18 achieved pCR (overall pCR rate 28%). In patients with HER2 expression above the 2200 cutoff (n = 30), the pCR rate was approximately 3 times higher than that of lower HER2 expressors (n = 35) (43% vs. 14%; [odds ratio = 4.47; [95% CI: 1.23-18.94], p = 0.013). Among the lower HER2 expressors, 86% did not achieve pCR. HER3 protein was co-expressed in 29 of 65 patient tumors including 50% of non-pCR samples.

**Conclusions:** In patients diagnosed as HER2+ using standard methods, a quantitative HER2 cutoff identified a subset of low HER2 expressors in which 86% did not achieve pCR on TNT. Quantitative proteomic testing may be more useful than standard HER2 assessment methods in predicting response to TNT. Multiplexed proteomic analysis of HER2 and HER3 co-expression could potentially inform treatment decisions regarding dual therapy with pertuzumab.
Clinicopathologic factors associated with pCR to neoadjuvant anti-HER2-directed chemotherapy

Jane L Meisel¹, Aili Suo², Caitlin E Taylor², Chao Zhang² and Xiaoxian Li². ¹Winship Cancer Institute at Emory University, Atlanta, GA and ²Emory University, Atlanta, GA.

**Background:** While the use of neoadjuvant therapy has become the standard of care in certain locally advanced breast cancers, questions remain regarding the optimal chemotherapeutic regimen as well as biologic and patient-specific predictors of pathologic complete response. In this study, we examined patient and tumor-specific characteristics associated with increased prediction of pathologic complete response (pCR) to neoadjuvant anti-HER2-directed chemotherapy.

**Methods:** 204 patients who received neoadjuvant anti-HER2-directed chemotherapy at our institution from 2006-2016 were included in this retrospective study. Univariate analyses were performed to analyze the relationships of multiple clinical and pathologic features to pCR rate. Multivariate analysis was also performed to evaluate the relative impact of specific pathologic characteristics on pCR rate.

**Results:** Among 204 patients with HER2 overexpressing breast cancers treated with neoadjuvant chemotherapy, 52.7% achieved pCR. Pathologic complete response was positively associated with high tumor grade (61.0% grade 3 in pCR group vs 39.0% in non-pCR group, P=0.23) and high Ki67 index (mean Ki67 59.1 in pCR group vs 47.4 in non-pCR; P= 0.015). It was also associated with HER2 IHC 3+ (57.1% in pCR group vs 42.9% in non-pCR, p=0.029), HER2 copy number (mean copy number 16.8 in pCR group vs 12.4 in non-PCR, p=0.004), and HER2/CEP 17 ratio (mean ratio 6.42 in pCR group vs 5.17 in non-pCR; P= 0.046). Rates of HER2 FISH positivity were equal in the pCR and non-pCR groups (50.8% vs 49.2%, p=0.062). Multivariate analysis demonstrated that higher Ki67 index and higher HER2/CEP17 ratio are significant predictors of pCR after adjusting for other covariates (odds ratio for Ki67 1.03 (1.06-1.49), p=0.002; for HER2/CEP17 ratio OR 1.26 (1.06-1.49), p=0.009).

**Conclusions:** In HER2 positive breast cancers, a higher Ki67 index as well as higher HER2/CEP17 ratios are associated with an increased pCR rate and may be useful as predictors of response prior to neoadjuvant therapy. Our results also demonstrate HER2 IHC to be a stronger predictor than HER2 FISH of response to upfront therapy. Larger studies would be useful as this association, if confirmed, may have relevance to clinical practice.
Predicting benefit from HER2-targeted therapies in patients with ER+/HER2+ breast cancer

Arran K Turnbull¹, Victoria Webber¹, Daniel McStay¹, Laura Arthur¹, Carlos Martinez-Perez¹, Anu Fernando¹, Lorna Renshaw¹, Jane Keys¹, Robert Clarke², Andrew H Sims¹ and J Michael Dixon¹. ¹Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom and ²Clarke Labs, Breast Cancer Research Laboratories, Georgetown University, Washington DC.

**Background:** ER+/HER2+ accounts for up to 10% of all breast cancers (BCs) and most are treated with endocrine therapy (ET) after surgery to reduce the recurrence risk. We developed and validated an immunohistochemistry (IHC) based test (EA2Clin) that incorporates baseline IL6ST, clinical variables and on-treatment measurement of MCM4. Responders (Rs) and non-responders (NRs) to ET are identified and it accurately estimates recurrence-free survival (RFS) and BC-specific overall survival (BCSS). The aim was to determine if EA2Clin could accurately predict ER+/HER2+ patients likely to benefit from ET and to determine if it can identify those for whom HER2-targeted therapies are required.

**Methods:** 3 cohorts were studied:

A: 32 post-menopausal women (PMW) with large ER+/HER2+ BC treated with neoadjuvant (3-6 months) then adjuvant letrozole. 5 also received adjuvant chemotherapy plus Herceptin. Neoadjuvant clinical response was assessed by changes in tumour volume. Tumour core biopsies were taken at 0, 14 days and 3 months. Gene expression analysis using Illumina HT12 whole-genome beadarrays was performed on a subset (n=17) where fresh tissue was available.

B: 13 PMW with ER+/HER2+ BC who were treated by surgery without neoadjuvant therapy. RNA was extracted from excision tissues and analysed using whole-genome Affymetrix U133A microarrays.

C: 15 PMW with ER+/HER2+ BC treated with 2-weeks of pre-operative letrozole (n=7) or anastrozole (n=8). All received adjuvant letrozole. Tissues were collected at pre-treatment and at surgery. None received Herceptin or chemotherapy. All patients were followed-up after surgery (median follow-up = 6.4 years).

**Results:** In cohort A, half (16/32) of the patients responded to ET with tumour volume reductions of >70% with neoadjuvant treatment. Innate resistance was apparent in 3 patients with continued tumour growth on ET, whereas 13 patients developed resistance after a period of response. EA2Clin predicted neoadjuvant response with a 92% accuracy. There was increased expression of phospho-AKT and phospho-ERK in NRs, not seen in Rs. Half (8/16) of the NR cancers expressed phospho-ER; but was not seen in any responsive cancer. Gene expression analysis in 17 patients showed increased MAPK and PI3K pathway activity in the 9 NR compared with the 8 R tumours. These results were recapitulated in cohort B where MAPK and PI3K activity were associated with low levels of IL6ST.

In the 16/32 patients who responded well to neoadjuvant ET the actuarial recurrence rate was 0% at 5 and 10 years. The rate of recurrence in the NR was 30% at both 5 and 10 years. Of the 5 patients who received chemotherapy plus Herceptin, none recurred despite a poor response to neoadjuvant letrozole (median length to last follow-up was 6.1 years). Initial data suggest that in cohort B EA2Clin identifies a group of ER+/HER2+ cancers that can be managed by ET alone.

**Conclusions:**

- The EA2Clin test identifies ER+/HER2+ BCs who respond well to ET alone and those with a poor clinical response who have higher risk of recurrence.
- NR to ET have increased expression of PI3K and MAPK pathways, consistent with active HER2 signalling.
- There is potential role for EA2Clin in selecting ER+/HER2+ patients that require and benefit from HER2-targeted therapies.
Profiling of metastatic carcinomas to the breast for the biomarkers of immuno-oncology therapy

Zoran Gatalica¹, Wijendra Senarathne¹, Semir Vranic² and Barbara A Pockaj³. ¹Caris Life Sciences, Phoenix, AZ; ²College of Medicine, Qatar University, Doha, Qatar and ³Mayo Clinic, Phoenix, AZ.

Introduction: Breast metastases from non-mammary carcinomas are very rare and the molecular characteristics of these metastases have not been studied. Due to the uniqueness of this type of metastases, we evaluated whether there was any molecular or immunologic similarities among the patients with metastases to the breast.

Patients and Methods: Fifty-one patients with metastatic carcinomas to the breast (49 female and 2 male) were identified in the files of Caris Life Sciences (Phoenix, AZ). Average age at presentation was 57 years (range, 20-90 years). Immunohistochemistry for PD-L1 was performed using SP142 (Ventana) or 22c3 (DAKO) antibodies; 592 genes sequencing (n=47), DNA microsatellite instability (MSI) (n=6) and total mutational burden (TMB) (n=14) were obtained from a next generation sequencing platform (Illumina).

Results: Three most common primary sites were lung (19, 37%), ovary (15, 29%) and fallopian tubes/peritoneum (7, 14%). Ten metastases (20%) demonstrated neuroendocrine differentiation. When 1% cutoff was applied, tumor cells PD-L1 expression was detected in 10 cases (20%), and immune cells expression of PD-L1 in 19 patients (37%). Three cases (6%) had PD-L1 staining in both cancer and infiltrating immune cells. 50% of the cases exhibited mutations in TP53 gene, while other mutated genes followed the pathways typically seen in their primary sites (e.g. VHL in renal carcinomas, BRCA1 in fallopian tube carcinoma). Total mutational burden was high (≥10 mutations/Mb) in five out of 14 successfully analyzed cases (36%) and no case (0%) exhibited high microsatellite instability. Interestingly, estrogen receptor status was positive in 13/49 patients (26.5%) including 12 adenocarcinomas originating from ovary, Fallopian tube or peritoneum and one duodenal neuroendocrine. No tumor was HER2 positive.

Conclusions: Metastases to the breast proved to be heterogeneous but there were molecular, endocrine and immunologic findings that yielded information that could be used to make therapeutic decisions which including the use of new immunotherapeutic strategies.
The impact of HER2-directed targeted therapy on HER2-positive DCIS of the breast

Gary D Lewis¹,², Waqar Haque², Andrew Farach², Sandra S Hatch¹, Edward B Butler², Mary R Schwartz², Elizabeth Bonefas³ and Bin S Teh³. ¹University of Texas Medical Branch-Galveston, Missouri City, TX; ²Houston Methodist Hospital, Houston, TX and ³Breast Health Houston, Houston, TX.

Purpose/Objectives: In invasive breast cancer, HER2 is a well-established negative prognostic factor. However, its significance on the prognosis of ductal carcinoma in situ (DCIS) of the breast is unclear. As a result, the impact of adding HER2-directed therapy to HER2-positive DCIS is unknown and is currently the subject of ongoing clinical trials. In this study, we aim to determine the impact of HER2 status on DCIS patient outcomes as well as the possible impact of HER2-directed targeted therapy on survival outcomes for HER2-positive DCIS patients.

Materials/Methods: The National Cancer Data Base (NCDB) was used to retrieve patients with biopsy-proven DCIS diagnosed from 2004-2015. Only patients with known estrogen receptor (ER) status, progesterone receptor (PR) status, and HER2 status were included in the analysis. Patients were divided into two groups based on the adjuvant therapy they received: systemic therapy (assumed to be HER2-directed targeted therapy) or no systemic therapy. Statistics included multivariable logistic regression to determine factors predictive of receiving systemic therapy, Kaplan-Meier analysis to evaluate overall survival (OS), and Cox proportional hazards modeling to determine variables associated with OS.

Results: Altogether, 1927 patients met inclusion criteria; 430 (22.3%) received HER2-directed targeted therapy, while 1497 (77.7%) did not. Patients who received HER2-directed targeted therapy were likely more likely to be ER-negative. Patients who received HER2-directed targeted therapy had a higher 5-year OS compared to patients that did not (97.7% vs. 95.8%, p = 0.043). This survival benefit remained on multivariate analysis. Factors associated with worse OS on multivariate analysis included Charlson-Deyo Comorbidity Score ≥ 2 and no receipt of hormonal therapy.

Conclusions: In the largest study to date evaluating HER2-positive DCIS patients, the receipt of HER2-directed targeted therapy was associated with an improvement in OS. The results of currently ongoing clinical trials are needed to confirm this finding.
tRNA-derived fragments as novel predictive biomarkers for trastuzumab-resistant breast cancer

Chunxiao Sun¹, Wei Li¹, Hao Wu¹, Xiang Huang¹, Jun Li¹, Ziyi Fu¹,²,³, Jinhai Tang¹ and Yongmei Yin¹. ¹The First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China; ²Nanjing Maternal and Child Health Medical Institute, Obstetrics and Gynecology Hospital Affiliated to Nanjing Medical University, Nanjing, Jiangsu, China and ³Northwestern University, Chicago, IL.

Background: Resistance to trastuzumab remains a common challenge to HER-2 positive breast cancer. Up until now, the underlying mechanism of trastuzumab resistance is still unclear. tRNA-derived small non-coding RNAs, a new class of small non-coding RNA (sncRNAs), have been observed to play an important role in cancer progression. However, the relationship between tRNA-derived fragments and trastuzumab resistance is still unknown.

Methods: We detected the levels of tRNA-derived fragments expression in normal breast epithelial cell lines, trastuzumab-sensitive and -resistant breast cancer cell lines using high-throughput sequencing. qRT-PCR was conducted to validate the differentially expressed fragments in sera from trastuzumab-sensitive and -resistant patients. A receiver operating characteristic (ROC) curve analysis was performed to evaluate the power of specific tRNA-derived fragments. Progression-free survival (PFS) was analyzed using Cox-regression.

Results: Our sequence results showed that tRNA-derived fragments were differentially expressed in the HBL-100, SKBR3, and JIMT-1 cell lines. tRF-30-JZOYJE22RR33 and tRF-27-ZDXPHO53KSN were found significantly upregulated in trastuzumab-resistant patients compared to sensitive individuals, and the ROC analysis showed that tRF-30-JZOYJE22RR33 and tRF-27-ZDXPHO53KSN were correlated with trastuzumab resistance. In a multivariate analysis, higher levels of tRF-30-JZOYJE22RR33 and tRF-27-ZDXPHO53KSN expression were associated with significantly shorter PFS in patients with metastatic HER-2 positive breast cancer.

Conclusion: Our results suggest that tRF-30-JZOYJE22RR33 and tRF-27-ZDXPHO53KSN play important roles in trastuzumab resistance. Patients with high levels of tRF-30-JZOYJE22RR33 and tRF-27-ZDXPHO53KSN expression benefitted less from trastuzumab-based therapy than those that express lower-levels of these molecules. tRF-30-JZOYJE22RR33 and tRF-27-ZDXPHO53KSN may be potential biomarkers and intervention targets in the clinical treatment of trastuzumab-resistant breast cancer.
Interaction between molecular subtype and stromal immune infiltration dynamics in breast cancer patients treated with neoadjuvant chemotherapy

Anne-Sophie Hamy¹,², Hélène Bonsang-Kitzis¹,², Diane De Croze³, Enora Laas², Lauren Darrigues², Lucian Topciu², Emmanuelle Menet³, Anne Vincent-Salomon², Florence Lerebours³, Jean-Yves Pierga²,⁴, Etienne Brain³, Jean-Guillaume Feron³, Gabriel Benchimol², Giang-Thanh Lam²,⁵, Marick Laé² and Fabien Reyal¹,²,⁴. ¹Residual Tumor & Response to Treatment Laboratory, RT2Lab, PSL Research University, INSERM, U932 Immunity and Cancer, Institut Curie, Paris, France; ²PSL Research University, Institut Curie, Paris, France; ³Hôpital René Huguenin, Saint-Cloud, France; ⁴Université Paris Descartes, Paris, France and ⁵Geneva University Hospitals, Geneva, Switzerland.

Purpose: High levels of tumor-infiltrating lymphocytes (TILs) before neoadjuvant chemotherapy (NAC) are associated with higher pathological complete response (pCR) rates, and better survival in TNBC and HER2-positive breast cancers (BCs). We investigated the value of changes in TIL levels and final TIL levels after treatment, by evaluating lymphocyte infiltration before and after NAC in a real-life BC cohort.

Patients and methods: We assessed stromal TIL levels in 716 pre- and post-treatment matched paired specimens, according to the guidelines of the international TIL working group.

Results: Pre-NAC TIL levels were higher in tumors for which pCR was achieved than in cases of residual disease (33.9% versus 20.3%, p=0.001), in luminal tumors and TNBCs, but not in HER2-positive BCs, (pInteraction =0.001). The association between pre-NAC TIL levels and pCR was non-linear in TNBCs (p=0.005). Mean TIL levels decreased during NAC (pre-NAC TILs: 24.1% versus post-NAC TILs: 13.0%, p<0.001). This decrease was strongly associated with high pCR rates, and TIL level variation was strongly inversely correlated with pre-NAC TIL levels (r=-0.80, p<0.001). Pre-NAC TILs and disease-free survival (DFS) were associated in a non-linear manner (p<0.001). High post-NAC TIL levels were associated with aggressive tumor characteristics and with impaired DFS in HER2-positive BCs (HR=1.04, CI [1.02-1.06], p=0.001), but not in luminal tumors or TNBCs (pInteraction =0.04).

Conclusion: The associations of pre, post-NAC TIL levels with response to treatment and DFS differ between BC subtypes and may deviate from linearity. The characterization of immune subpopulations may improve our understanding of the complex interactions between pre- or post-NAC setting, BC subtype, response to treatment and prognosis.
Breast cancer-specific mortality (BCSM) in patients (pts) with node-negative (N0) and node-positive (N+) breast cancer (BC) guided by the 21-gene assay: A SEER-genomic population-based study

Gabriel N Hortobagyi1, Steven Shak2, George W Sledge, Jr.3, Eric P Winer4, Kathy S Albain5, Eleftherios P Mamounas6, Debbie M Jakubowski7, Valentina I Petkov7 and Norman Wolmark8. 1University of Texas MD Anderson Cancer Center, Houston, TX; 2Genomic Health, Inc., Redwood City, CA; 3Stanford University, Stanford, CA; 4Dana-Farber Cancer Institute, Boston, MA; 5Loyola University Chicago Cardinal Bernardin Cancer Center, Maywood, IL; 6Orlando Health UF Health Cancer Center, Orlando, FL; 7National Cancer Institute, Bethesda, MD and 8NSABP Foundation, Pittsburgh, PA.

Introduction: The 21-gene Breast Recurrence Score® (RS) in the randomized NSABP B-20, SWOG S8814, and TAILORx studies predicted chemotherapy (CT) benefit for pts with N0 and N+ disease. Endocrine therapy was not inferior to chemoendocrine therapy in 6,711 randomized TAILORx pts with RS 11-25 and N0 disease. We characterized BCSM for the TAILORx-defined RS groups (0-10, 11-15, 16-20, 21-25, and 26-100) in the large population-based SEER study of pts treated based on RS results. Methods: RS results were provided electronically to SEER registries per their linkage methods (Petkov npj Breast Cancer 2016). Eligible pts were diagnosed Jan 2004 - Dec 2014 with N0 and N+(N1mic, 1-3 positive nodes[N1]), HR+, HER2-negative BC, and had no prior malignancy or multiple tumors, with follow-up information through Dec 2015. BCSM estimates by reported CT use yes vs. no/unknown were computed, and must be interpreted cautiously given lack of randomization.

Results: There were 80,605 pts with RS results; 70,087 with N0 disease, 4,336 with N1mic, and 6,182 with N1. Median follow-up was 49 months, with 20,151 pts followed >76 months. 1,020 pts had experienced breast cancer death. There was a significant positive association between higher RS results and increased BCSM (p<0.001) without and with adjustment for nodal status, age, tumor size, and grade. Reported CT use increased with increasing RS result (Table). 9-y BCSM was <4% without CT for pts with RS 0-25 and N0 disease and for pts with RS 0-20 and N1 disease. For RS 26-100, 9-y BCSM was lower with CT use than without (Table). Similar results were seen in the 4,336 pts with N1mic disease. Pts treated with CT for every RS group, as expected, tended to have higher risk features (age, tumor size and grade), and multivariable models and adjustment by propensity scores will be presented to allow for more definitive conclusions.

Conclusion: In both N0 and N+ disease (up to 3 positive nodes), low RS results identify more than 70% of BC patients with excellent long-term outcomes and no apparent CT benefit, and high RS results (26-100) identifies an important minority of
patients where CT reduces BCSM. Real-world evidence from SEER reconfirms that the 21-gene assay is prognostic and strongly suggests it is predictive of CT benefit, irrespective of nodal status.
Validation of CIN4 in the DBCG 89D clinical cohort

Melanie Spears¹,², Maj-Britt Jensen³, Nicola Lyttle¹, Linda Liao¹, Anne-Vibeke Laenholm⁴, Bent Ejitlertsen³ and John MS Bartlett¹,². ¹Ontario Institute for Cancer Research, Toronto, Canada; ²University of Toronto, Toronto, Canada; ³Danish Breast Cancer Cooperative Group, Copenhagen, Denmark and ⁴Slagelse Hospital, Slagelse, Denmark.

Background: Chromosome instability (CIN) in solid tumours is associated with poor prognosis and results in numerical and structural chromosomal aberrations. Our group previously have developed the CIN signatures and have demonstrated the CIN signatures as prognostic biomarkers in breast cancer cohorts. Furthermore, our work in the BR9601 and MA.5 clinical cohorts CIN4 provided level IIB evidence that CIN4 was predictive of anthracycline sensitivity. An analysis of the DBCG 89D clinical trial was now performed to validate the role of CIN gene expression signatures as a marker of anthracycline sensitivity.

Methods: RNA was extracted from patients in DBCG 89D clinical trial analysed through NanoString technology. The prognostic and predictive values of the signatures on distant relapse-free survival (DRFS) were explored using Cox proportional hazard models. Multivariate models included menopausal status, tumour size, nodal status, ER and Her2 status, histological type and grade, and treatment regimen.

Results: All of the 594 samples available from the DBCG 89D we successfully analysed. CIN25 and CIN70 gene expression signatures did not associate with any of the clinicopathological characteristics tested. In addition, CIN25 and CIN70 were not prognostic or predictive of distant relapse free or breast cancer specific survival in this clinical cohort. Low CIN4 score was associated with ER negativity (p=0.02), HER2 normal expression (p<0.05).

Conclusion: In this study we demonstrated that CIN4 was associated with aggressive disease. We were however in DBCG 89D unable to validate the predictive value of CIN4 concerning anthracycline sensitivity.
A model to predict high-risk Oncotype DX scores as defined by the TailorX trial: A report from the National Cancer Data Base

Catherine Pesce¹, Kristine Kuchta¹, Edward Wang¹, Katharine Yao¹ and Mahmoud El-Tamer². ¹NorthShore University HealthSystem, Evanston, IL and ²Memorial Sloan-Kettering Cancer Center, New York, NY.

Background: Results from the TailorX clinical trial demonstrated a survival benefit of chemotherapy in those with high-risk (>25) Oncotype DX scores as well as in some patients ≤50yo with intermediate (16-25) scores. The objective of this study was to develop a model that could predict a high-risk Oncotype DX score based on tumor features alone.

Methods: From 2010-2015, 84,549 breast cancer patients with Oncotype DX scores were selected from the National Cancer Data Base. Seven pathologic variables including age, estrogen and progesterone receptor status, histologic subtype, lymphovascular invasion (LVI), grade, and tumor size were used to predict high-risk (>25) Oncotype DX scores using logistic regression. A similar analysis was performed on women ≤50yo to predict low (<15) and intermediate (16-25) scores. Nomograms were created for models using bootstrap estimation method of the model coefficients. Cutoffs with at least 80% positive predictive value (PPV) were chosen to classify patients into high or low-risk Oncotype DX score groups. Accuracy of these predictions were developed in a training set and validated in a testing set.

Results: For patients >50yo, 6,658 (15.1%) of patients had high-risk Oncotype DX scores. The model yielded a moderately strong C-index of 0.80 for Oncotype DX score of >25. For women ≤50yo, 2,044 (13.5%) were high-risk, 5,760 (38.1%) were intermediate-risk and 7,316 (48.4%) were low-risk. The C-index for women ≤50yo was 0.81 for prediction of Oncotype DX score of >25. C-indexes for intermediate and low risk scores were not strong enough to use for prediction (0.54 and 0.67). Estrogen receptor status, progesterone receptor status and grade were the strongest independent predictors of high-risk Oncotype DX scores in women >50yo and ≤50yo. Age was not a good predictor of high-risk scores in women >50yo. When our nomogram was used in the training set, the PPV of a high-risk Oncotype score was 80% with a negative predictive value (NPV) of 87%, sensitivity of 19% and specificity of 99%. In the testing set, PPV was 81%, with a NPV of 87%, sensitivity of 19% and specificity of 99%.

Conclusion: A model incorporating tumor factors can predict a high-risk Oncotype DX score as defined by the recent TailorX trial in all age groups. The model is of limited value in predicting intermediate-risk Oncotype DX scores in women of age ≤50. In resource-constrained healthcare systems, such a model can help identify high risk patients who would benefit from adjuvant chemotherapy without incurring the cost of an Oncotype DX test.
Predictive gene signatures of adjuvant capecitabine benefit in triple negative breast cancer in the FinXX trial

Saranya Chumsri¹, Karama Asleh², Heather Ann Brauer³, Afshin Mashadi-Hossein⁴, L Susanna Lauttia⁴, Henrik Lindman⁵, Torsten O Nielsen², Heikki Joensuu⁴ and E Aubrey Thompson¹. ¹Mayo Clinic, Jacksonville, FL; ²The University of British Columbia, Vancouver, BC, Canada; ³NanoString, Seattle, WA; ⁴University of Helsinki, Helsinki, Finland and ⁵Uppsala University Hospital, Uppsala, Sweden.

Background: Recent studies have demonstrated a benefit of adjuvant capecitabine in early stage breast cancer, particularly in patients with residual disease after neoadjuvant chemotherapy. Subset analyses suggest that patients with triple negative breast cancer (TNBC) may be more likely to benefit with capecitabine in this setting. However, more precise biomarkers to predict which patients are most likely to benefit from capecitabine are needed.

Methods: The NanoString Breast Cancer 360™ (BC360) panel was used to quantify mRNA expression in FFPE tissue samples from patients with TNBC in the FinXX trial. Gene signature scores were analyzed using prespecified algorithms developed by NanoString. 30 additional custom genes related to capecitabine metabolism and function were added. Patients in FinXX trial were randomized to receive either 3 cycles of docetaxel followed by 3 cycles of cyclophosphamide, epirubicin, and fluorouracil (T+CEF) or 3 cycles of docetaxel plus capecitabine followed by 3 cycles of cyclophosphamide, epirubicin, and capecitabine (TX+CEX). Cox proportional hazard ratio (HR) was used to determine the association of each gene signature with recurrence free survival (RFS).

Results: A total of 111 samples from patients with TNBC in the FinXX trial were available for gene expression analysis. 57 patients were treated with T+CEF and 54 patients were treated with TX+CEX. The median age was 52 years and median follow up was 10.2 years. Consistent with the previous analysis of the FinXX trial, patients with TNBC had nonsignificant but favorable RFS with capecitabine (HR 0.60, 95% CI 0.27-1.3, p 0.2). Among 39 individual genes and metagene signatures generated with the BC360 panel, there were 4 gene signatures significantly associated with improved RFS favoring an addition of capecitabine with TX+CEX compared to T+CEF. These were the cytotoxic cell signature (HR 0.37, 95%CI 0.15-0.92, p 0.03), endothelial signature (HR 0.18, 95%CI 0.04-0.83, p 0.03), mast cell signature (HR 0.43, 95%CI 0.21-0.88, p 0.02), and PDL2 gene (HR 0.29, 95%CI 0.09-0.99, p 0.05). PAM50 intrinsic subtype was not predictive of capecitabine benefit within this TNBC subset. Moreover, we identified additional individual 12 genes that were significantly associated with capecitabine benefit (p-FDR<0.05). Among these genes, high expression of CES1, which encodes an enzyme that activates capecitabine, was significantly associated with improved RFS when treated with capecitabine (HR 0.71, 95%CI 0.32-1.61 with p-interaction=0.04).

Conclusion: Our analyses demonstrated potential predictive individual genes and metagene signatures that may be used to identify TNBC patients who are more likely to benefit from adjuvant capecitabine. Interestingly, several gene signatures related to immune response and genes related to capecitabine activation were associated with improved outcome in TNBC patients treated with capecitabine in the FinXX trial. While these findings are compatible with basic science reports, future studies are needed to validate the significance of these gene signatures as predictive biomarkers for capecitabine benefit.
HRD (homologous recombination deficiency) score and its clinicopathological features in neoadjuvant chemotherapy treated sporadic breast cancers

Seiichi Imanishi¹, Yasuto Naoi¹, Kenzo Shimazu¹, Masashi Shimoda¹, Naofumi Kagara¹, Tomomori Tanei¹, Tomohiro Miyake¹, Seung J Kim¹ and Shinzaburo Noguchi¹. ¹Osaka University Graduate School of Medicine, Suita City, Osaka pref, Japan.

Purpose Homologous Recombination Deficiency (HRD) score has been developed to evaluate the DNA double-strand break repair function. BRCA1/2 germline mutation-associated breast cancers are known to show a high HRD score and a high sensitivity to platinum-based chemotherapy as well as PARP inhibitor. HRD can be theoretically induced by not only the dysfunction of BRA1/2 but also the dysfunction of the other molecules involved in homologous recombination, and, actually, high HRD score is reported to be seen in a significant proportion of sporadic breast tumors without BRCA1/2 mutation. The aim of the present study was to elucidate the clinicopathological characteristics of sporadic breast tumors with high HRD score as well as their sensitivity to sequential paclitaxel and FEC chemotherapy (P-FEC).

Methods Tumor tissues obtained by Mammotome from 132 sporadic breast cancer patients (stage II-III) before neoadjuvant chemotherapy with P-FEC were subjected to assay for HRD score using Oncoscan CNV kit®. HRD score was a simple sum of NtAI, LOH, and LST (cutoff, 42), and were also subjected to the gene expression analysis using the Affymetrix microarray (U133 plus 2.0). BRCA1 promoter methylation was assayed by methylation specific real-time PCR.

Result Of the 132 breast tumors, 32% showed a high HRD score which were significantly associated with high histological grade (P=0.001), negative progesterone receptor (P=0.023) and high Ki67 index (P=0.004). Triple negative breast cancer (TNBC)(n=19) showed a significantly (P<0.001) higher HRD score than the other subtypes (HR+/HER2-(n=73), HR+/HER2+(n=12), HR-/HER2+(n=18)). BRCA1 promoter methylation was significantly associated with a high HRD score. There was no significant correlation between HRD score and pCR to P-FEC when all tumors were considered but tumors with a high HRD score showed a significantly (P=0.020) lower pCR rate when only TNBC were considered. In TNBC, majority of tumors showed a high HRD score in five subtypes (BL1, BL2, IM, M, MSL) but no tumor showed a high HRD score in LAR (luminal androgen receptor) subtype.

Conclusion Approximately one third of sporadic breast tumors show a high HRD score, indicating the presence of homologous recombination dysfunction, and they are most often seen in TNBC with BRCA1 promoter methylation and never in LAR subtype. Interestingly, breast tumors with a high HRD score were less sensitive to P-FEC.
Exploratory biomarker analysis from a phase II, multicenter, randomized trial of eribulin plus gemcitabine (EG) versus paclitaxel plus gemcitabine (PG) as first-line chemotherapy for human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC): Korean cancer study group trial (KCSG BR13-11)

Ji-Yeon Kim, Eun Jin Lee, Kyung Hee Park, Seock-Ah Im, Sung-Bae Kim, Soo Hyuk Sohn, Keun Seok Lee, Yee Soo Chae, Ki Hyeong Lee, Jae Hyun Kim, Young-Hyuck Im, Tae-Yong Kim, Kyung-Hun Lee, Jin-Hee Ahn, Gun Min Kim, In Hae Park, Soo Jung Lee, Hye Sook Han, Se Hyun Kim, Kyung Hae Jung, and Yeon Hee Park.

1Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; 2Samsung Genome Institute, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; 3Seoul National University Hospital, Cancer Research Institute, Seoul National University, College of Medicine, Seoul, Korea; 4Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; 5Yonsei University College of Medicine, Seoul, Korea; 6Center for Breast Cancer, National Cancer Center, Goyang, Korea; 7Kyungpook National University Medical Center, Daegu, Korea; 8Chungbuk National University Hospital, Cheongju, Korea and 9Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Korea.

Introduction: A phase II, multicenter, randomized clinical trial of the comparison between eribulin plus gemcitabine (EG) and paclitaxel plus gemcitabine (PG) as first-line chemotherapy for patients with human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC) found EG was less neurotoxic, but had similar efficacy of PG. In this study, we performed exploratory biomarker analysis of the impact of genetic alterations on the efficacy according to EG and PG chemotherapy.

Methods: This biomarker study was conducted using tumor samples from 40 patients. When tissue collection was possible after disease progression, we performed paired sample analysis. Tumor DNA and RNA were extracted from formalin-fixed, paraffin-embedded tissues. To perform targeted deep sequencing, we used CancerScan™, a 375 cancer gene panel. And we performed an nCounter expression assay for gene expression analysis using 730 PanCancer panel and 730 Immune panel.

Results: In total, we obtained 44 tissue samples from 40 patients. Twenty two patients were assigned in EG arm and 18 patients were in PG arm. Thirty-eight were at baseline and six after disease progression. Gene expression assay were performed in 44 tissue samples but only 31 samples were possible to be targeted deep sequencing. We performed differently expressed gene (DEG) analysis for detecting the association between level of gene expression and disease progression. In this analysis, high expression of CCNE1, TGFB4 and BAMBI and low expression of DDB2, CD14 and SHC3 were associated with disease progression among 730 PanCancer panel genes (p<0.05, respectively). In terms of immune panel genes, most of immune related genes were highly expressed in a group without disease progression compared with that with disease progression. Only 2 genes, C8G and CD24 were highly expressed in a group with disease progression. Paired sample analysis showed that expression levels of THBS4 and CD27 decreased after disease progression while those of CCNE2 and FGFR4 increased.

In targeted deep sequencing, FAT3 (42.3%) was most frequently mutated gene followed by PKHD1, PIK3CA and TP53. Among mutated genes, EWSR1 mutation and upstream mutation of ETV1 were associated with disease progression, respectively (p<0.05, respectively). In mutation signature analysis, signature 1 (S, age related), S3(homologous recombination deficiency, HRD), S6 (mismatch repair, MMR), S20(MMR) and S21(microsatellite instability, MSI) were enriched in this population. Mutation signature 3 related to short disease free survival (p=0.0026).

Conclusion: In gene expression analysis, high expression of TGF-B signaling pathway related genes was associated with disease progression while high expression of immune related genes were related to prolonged disease free survival. In mutation analysis, EWSR1 and ETV1 mutations indicated short disease free interval and HRD mutation signature was also related to poor prognosis.
Sperm associated antigen 5 (SPAG5) predicts pathological complete response (pCR) and distant relapse risk to HER2 targeting agents and anthracycline based chemotherapy in HER2 positive (HER2+) breast cancer (BC)

Tarek MA Abdel-Fatah¹, Graham R Ball², Ian O Ellis³, Arlene Chan⁴ and Stephen YT Chan¹. ¹Nottingham University Hospital NHS Trust, Nottingham, United Kingdom; ²John van Geest Cancer Research Centre, School of Science and Technology, Nottingham Trent University, Clifton Campus, Nottingham, United Kingdom; ³School of Medicine, University of Nottingham and Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom and ⁴Curtin Health Innovation Research Institute, Curtin University, Perth, Australia.

Background:
Previously we found that SPAG5 gene was amplified/gained in 20-35% of HER2+BC. Herein, we investigated the prognostic and predictive significance of SPAG5 (mRNA, protein) expression in 1726 HER2+BC patients with median follow-up >5 years.

Methods:
Analysis of SPAG5 mRNA (cDNA array expression) and protein (immunohistochemistry) and their association with distant relapse risk (DRR) were determined in 446 and 642 cases of HER2+ early stage BC in which 36% and 40% of them had received adjuvant Herceptin (H) + Anthracycline based (AC) + Taxane (T); respectively. In 33% and 31% of SPAG5 mRNA cohort and 21% and 38% of SPAG5 protein cohort had received adjuvant (Adj) AC+T or chemotherapy (CT) naïve; respectively. The association between SPAG5 expression (mRNA, protein) and both pCR and DRR after receiving neoadjuvant chemotherapy (Neo-Adj-CT) were evaluated in 476 and 162 patients with HER2+ locally advanced BC; respectively. Neo-Adj AC+T+HER2 targeting (Herceptin, Herceptin+ Lapatinib or Lapatinib) and AC+/-T has been prescribed to 51% and 49% of mRNA cohort whereas the 45% and 49% of the protein expression cohort has received Neo-Adj AC+T+H and AC+/-T; respectively.

Findings:
In patients with SPAG5 mRNA overexpression (+;> median), those who had received AC+/-T Neo-Adj-CT alone achieved similar pCR to those who had received AC+T+HER2 targeting Neo-Adj (38% vs., 37%; OR (95% CI): 1.0 (0.6–1.6), p=0.923) in either ER- (46% vs., 52%; OR (95% CI): 1.3 (0.5–3.0), p=0.58) or ER+ subgroups (25% vs., 26%; OR (95% CI): 1.1 (0.4–3.4), p=0.88). Whereas in patients with low SPAG5 mRNA (-), those who had received AC+T+HER2 targeting Neo-Adj had achieved 2.5 fold increased in pCR compared to those who received AC+/-T alone (47% vs., 26%; OR (95% CI): 2.5 (1.4–4.4), p=0.001) in either ER- (60% vs., 31%; OR (95% CI): 3.4 (1.7–6.7), p<0.001) or ER+ subgroups (42% vs., 16%; OR (95% CI): 4.0 (1.2–12.9), p=0.018). Similarly in patients with SPAG5- protein expression; receiving AC+T+HER2 targeting Neo-Adj was associated with higher pCR compared to AC+/-T (21% vs., 4%; OR (95% CI): 6.6 (1.4–32.6), p=0.01). Whereas receiving AC+/-T was associated with similar pCR to AC+T+HER2 targeting Neo-Adj in patients with SPAG5+ protein (49% vs., 53%; OR (95% CI): 1.2 (0.5–3.2), p=0.702). Receiving AC+T+HER2 targeting Neo-Adj was associated with lower DRR compared to AC+/-T [HR (95% CI): 0.82 (0.08-0.97); p=0.045] in patients with SPAG5- protein expression but not in those with SPAG5+ protein [HR (95% CI): 1.08 (0.34-3.36); p=0.901]. Similarly, receiving Adj Herceptin+AC+T was associated with lower DRR compared to AC+/-T alone in those with SPAG5- (mRNA, protein) expression [HR (95% CI): 0.48 (0.25-0.93); p=0.029 and 0.82 (0.08-0.97); p=0.045; respectively] but not in those with high SPAG5+ (mRNA, protein) [HR (95% CI): 1.04 (0.48-2.26); p=0.924 and 1.00 (0.82-1.22); p=1.00; respectively.

Conclusion: SPAG5 expression could help in selecting patients who would benefit from both HER2-targeting agents and or AC-CT. Therefore patients with SPAG5- expression could avoid unnecessary AC-CT whereas those with SPAG5+ could receive a shorter Herceptin course.
On-treatment biomarkers improve prediction of response to neoadjuvant chemotherapy in breast cancer

Richard J Bownes¹, Arran Turbull¹, Carlos Martínez-Pérez¹, Andrew H Sims¹ and Olga Oikonomidou¹. ¹Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom.

Background
Neoadjuvant chemotherapy is increasingly used to treat breast cancer. Patient matched samples taken before and on-treatment can potentially provide valuable prognostic information from changes in gene expression. This study aims to identify whether on-treatment changes in gene expression in chemotherapy-treated cohorts can improve accuracy of response and outcome prediction over existing prognostic tests.

Methods
A total of 97 samples from a cohort of 50 neoadjuvant chemotherapy-treated primary breast cancer patients (aged 29-76 at diagnosis, Allred status 47:53% +/-, Her2 status 80:20% +/-, mixed grade and menopausal status) taken pre-treatment, at 2 weeks on-treatment, mid-therapy and at resection were sequenced with Ion Ampliseq transcriptome yielding expression values for 12,635 genes. Differential expression analysis was performed across response groups (16 Responders, 34 Non-Responders) as defined by Pathological Complete Response and over treatment time to identify significantly differentially expressed genes indicative of response status. The resulting gene lists were used for pathway enrichment analysis to find common up/down regulated pathways unique to each response class. Feature selection was performed with pairwise ranked products (FDR > 0.05) and the results used in a random forest model to generate a binary classifier. Results were validated in a similar, contemporary dataset from the I-SPY 1 Trial (221 evaluable patients, 36 with matching samples).

Results
On-treatment samples saw significant changes in genes commonly associated with proliferation (PCNA, AURKA, MKI67) regardless of response class. An on-treatment marker for response was identified (AAGAB), which resulted in a testing accuracy of 100% and a validation accuracy of 78% in the I-SPY 1 Trial. AAGAB was predictive of long term survival (p = 0.048 testing, p = 0.0031 validation) in both chemotherapy cohorts at the same expression level as defined for treatment response. The single gene on-treatment biomarker, AAGAB proves more performant than established prognostic tests, Mamaprint (Edinburgh NEO trial, pre-treatment 61%, on-treatment 63%, I-SPY 1 trial, pre-treatment 60%, on-treatment 66%) and Pam50 RORS (NEO trial pre-treatment 50%, on treatment 58%, I-SPY 1 trial pre-treatment 56%, on-treatment 64%) AAGAB was not predictive of response or survival in endocrine therapy treated cohorts.

Conclusion
Changes in gene expression of on-treatment chemotherapy breast cancer resulted in the identification of a novel gene marker that was as effective in predicting prognostic status as established prognostic tests. These results support the use of on-treatment testing in breast cancer to improve the accuracy of tumour response prediction.
Prosigna prognostic signature in pN1mi, estrogen receptor-positive breast cancer: the pN categorization impacts the BC risk stratification

Emmanuelle Charafe-Jauffret1, Raphaelle Duprez-Paumier2, Anca Berghian3, Frederique Penault-Llorca4, Marie Mélanie Dauplat1, Agathe Boucraut1, Monique Cohen1, Gilles Houvenaeghel1, Christine Maroc1, Anne Pradines2, Anne Cayre4, Pascaline Etancelin3 and Magali Lacroix-triki5. 1Institut Paoli-Calmettes, Marseille, France; 2IUCT, Toulouse, France; 3CHB, Rouen, France; 4CJP, Clermont Ferrand, France and 5IGR, Paris, France.

Background
Several validated molecular subtyping tests for breast cancer based on gene expression profiling are now routinely used in clinical practice. The Prosigna® breast cancer (BC) prognostic gene signature assay identifies a gene-expression profile that permits the classification of tumors into subtypes and gives a score for the risk of recurrence (ROR) at 10 years. The assay uses the 50-gene expression profile, weighted together with clinical variables, to generate a risk category and numerical score. The score is reported on a 0-100 scale, for hormone receptor positive BC. Prosigna test results classified tumors according to intrinsic subtypes (Lum A, Lum B, HER2-enriched, basal-like) and ROR risk groups (low risk, 0-40; intermediate risk, 41-60; and high risk, 61-100).

For node-positive patients, the weight given to the node status is similar when considering pN1mi ([0.2-2mm]) or pN1 (>2mm, 1-3 positive lymph nodes). Our aim was to characterize the Prosigna test classification of the pN1mi subgroup in the French national registry for molecular signatures in ER+ BC.

Methods
Since 2018, four French laboratories using Prosigna test in clinical practice retrospectively implement a national registry for molecular prognostic signatures in ER+ BC. We analyzed the pN1mi subgroup with regards to their clinico-pathological characteristics, Prosigna test results and ROR risk score. Using the definition formula of the prosigna algorithm, we could calculate a hypothetical score if the pN1mi has been considered as N+ and redefine risk categories for pN1mi breast cancers.

Results
The database included 886 tests performed in routine practice, including 91 (10.3%) pN1mi. The pN1mi BC were ER+ HER2-, invasive carcinoma of no special type in 81/91 (89%), with a median tumor size of 23 mm (range 12-60). Among these, the median ROR score was 44, and 51/91 tumors (56%) were classified as LumA tumors, 34/91 (41%) as LumB, two as HER2-enriched and one as basal-like. Interestingly, the probability of distant recurrence was 26% if pN1mi BC were considered as N+ but lowered to 10% if considered as pN0. Among the different molecular subtypes, the change from pN1 top N0 has different weight: in Lum A tumors, the switch in the probability of distant recurrences was 13 to 6% according to pN categorization of the pN1mi BC, and the median ROR score moved from 27 to 6 with 15/51(29%) of Lum A tumors considered as high risk if pN1 but only 1/51 if pN0; 31/51 (61%) versus 14/51 (27.5%) were in the intermediate risk group, and only 5/51 (10%) versus 34 (67%) in the low risk group. For LumB tumors, the switch in the probability of distant recurrences was 29% to 17% according to pN categorization and the median ROR score moved from 60 to 15 with 36/37(97.3%) of Lum B tumors considered as high risk if pN1but only 13/37(35%) ifp N0; 1/37 versus 20/37 (54%) were in the intermediate risk group, and none of the 37 LumB versus 1 in the low risk group.

Conclusion
With regards to Prosigna test in pN1mi BC - and the persistent debate as to whether they should bear the same weight as pN1 pN0 tumors - categorization in ROR risk group is likely to be impacted by the node factor weight, and more importantly among Lum B tumors.
Prediction of treatment response to neoadjuvant chemotherapy in breast cancer by subtype using tumor-infiltrating lymphocytes: Study of a large Mexican cohort

Saul Campos Gomez1, Nora Cabañas Chávez1, Jesus Hernández Alvarez1 and Karen Campos Gómez1. 1Centro Oncologico Estatal ISSEMyM, Toluca, Mexico.

Background/aim: Tumor-infiltrating lymphocytes (TILs) are emerging as biomarkers mediating tumor response to treatments. Studies have provided evidence that the level of TILs has prognostic value in breast cancer. The level of TILs has been associated with treatment outcome and pathologic response in patients undergoing neoadjuvant chemotherapy. In this study, we analyzed TILs before neoadjuvant therapy and if they correlate with pathological response to treatment.

Patients and methods: We retrospectively analyzed the specimen slides of patients with Breast Cancer from the Centro Oncologico Estatal ISSEMyM treated with Neoadjuvant Chemotherapy (NAC) during 2007–2014. We identified 410 patients fulfilling the inclusion criteria of this study. The histological sections had already been evaluated by hematoxylin and eosin slides. They were reassessed by our pathologist for the percentage of intratumoral and stromal TILs. The correlation with pathological response of the tumor after neoadjuvant therapy was also studied in these patients. The proportions of TILs were categorized into high and low groups using a cut-off value of 10%.

Resultados: The mean age was 51.4 years. The most frequent type of breast cancer histology was invasive ductal breast carcinoma in 369 (90%) patients, 34 (8.3%) lobular and 1.7% other. The BC subtypes among the 410 patients who received NAC were TNBC in 82 (20%), HER2BC in 70 (17.1%), and HRBC in 258 (62.9%) patients. Treatment response was pCR in 164 (40%) and non-pCR in 245 (60%) patients. Based on subtype, pCR was achieved in 43 (52 %) patients with TNBC, 35 (50.0%) with HER2BC, and 87 (33%) with HRBC. There were 191 (46.5%) patients in the high-TIL group and 219 (53.5%) patients in the low-TIL group. Patients were divided into high-TIL and low-TIL groups, and the clinicopathological characteristics of each group were examined. High TILs that had a pathologically complete response were found in 56 % of patients, and low TILs were found in 44 %. There was a significant correlation between TILs and pathological response in patients with neoadjuvant chemotherapy (p = 0.04).

Conclusion: TILs may be a biomarker for predicting treatment response to NAC in patients with Breast Cancer. Studies assessing outcomes and therapeutic efficacies should consider.
Biomarker phase neo-DDRD trial: Predicting response to neoadjuvant chemotherapy (NAC) in early breast cancer using the DNA damage repair deficiency (DDRD) assay

Eileen E Parkes¹, Colin R James², Tong Lioe³, Steven Walker⁴, Kieran I Savage¹, Keith Lowry², Laura Knight³, Andrena McCavigan³, Gemma Logan³, Jane Hurwitz³, Stephen J Kirk⁴, Paul Harkin³, Richard D Kennedy³ and Stuart A McIntosh¹. ¹Centre for Cancer Research & Cell Biology, Queen's University Belfast, Belfast, United Kingdom; ²Belfast City Hospital, Belfast Health & Social Care Trust, Belfast, United Kingdom; ³Almac Diagnostics, Craigavon, United Kingdom and ⁴Ulster Hospital Dundonald, Belfast, United Kingdom.

Background: The DDRD assay was developed to prospectively identify a molecular subtype of cancers defined by DNA damage activated immune signalling. This 44-gene assay has been validated to predict response to anthracycline-cyclophosphamide chemotherapy in both the adjuvant and neoadjuvant settings in breast cancer. The biomarker phase Neo-DDRD trial assessed the clinical utility of this assay prospectively in patients receiving neoadjuvant chemotherapy (NAC).

Methods: 48 patients receiving NAC for early (T1-2, N0-1) or locally advanced non-metastatic breast cancer were recruited from March 2014 – Sept 2017. Chemotherapy regimen was selected according to local standard-of-care guidelines (FEC “100” in N0, FEC-D in N1, FEC-DH in HER2 +ve, with the addition of pertuzumab when approved). The DDRD score was applied to RNA expression data obtained from pre-treatment FFPE core biopsies using a custom cDNA microarray (Breast Cancer DSA™). Response to NAC was assessed on resection specimens following definitive surgical treatment by pathologists blinded to the DDRD scores, using the Residual Cancer Burden (RCB) assessment tool.

Results: Patients with a positive DDRD assay call had an odds ratio for pathological complete response (pCR) or minimal residual disease (RCB0/RCB1) of 4.64 (95%CI 1.31-16.42; p = 0.0174). Patients with RCB0/RCB1 had significantly higher DDRD assay score than those with class RCB2/RCB3 responses (p =0.0011; unpaired t-test). Tumour subtype and DDRD call are summarised in Table 1.

Table 1: Tumour subtype distribution and DDRD assay result

In total, 29.2% of patients had a pathological complete response (pCR) (RCB0). Tumor infiltrating lymphocytes (TILs) were assessed on baseline pre-treatment samples. Increasing DDRD assay score was not significantly associated with increasing stromal TILs (p=0.1403; Pearson correlation). In assessing correlation between stromal TILs and response to chemotherapy, there was no significant difference found across RCB categories (p=0.45; one way ANOVA).

Conclusions: Preliminary results from the Neo-DDRD biomarker phase trial support the ability of the DDRD assay to predict response to neoadjuvant chemotherapy. The DDRD assay was confirmed to be a better predictor of neoadjuvant chemotherapy response than the presence of TILs. Translational work from this trial is ongoing: serial tissue and plasma samples collected at treatment mid-point and surgical resection will be used to study changes in RNA expression profiles in both DDRD assay positive and negative during chemotherapy, as well as changes in tumour immune infiltrates, peripheral chemokines and circulating tumour DNA profiles. Based on the results from this pilot study, we propose a biomarker-driven phase II trial in the neoadjuvant setting using the DDRD assay to stratify patients for treatment.
On-treatment biomarkers can improve prediction of response to neoadjuvant chemotherapy in breast cancer

Richard J Bownes¹, Arran K Turnbull¹, David Cameron¹,², Andy H Sims¹ and Olga Oikonomidou¹,². ¹University of Edinburgh, Cancer Research UK Edinburgh Centre, MRC Institute of Genetics and Molecular Medicine, Edinburgh, Edinburgh, United Kingdom and ²Edinburgh Cancer Centre, Western General Hospital, Edinburgh, United Kingdom.

Purpose: Neo-Adjuvant chemotherapy treatment is increasingly being used in breast cancer to preoperatively shrink tumour volumes and facilitate surgical plans. These datasets however, are still scarce, making it difficult to assess the relative value of multiple time point biopsies compared to diagnostic only sampling. This study aims to identify sequential samplings intrinsic value.

Method: A total of 97 samples from a cohort of 50 neoadjuvant chemotherapy treated primary breast cancer patients (aged 29-76 at diagnosis, Allred status 47:53% +/-, Her2 status 80:20% +/-, mixed grade and menopausal status) taken pre- treatment, at 2 weeks on-treatment, mid chemotherapy and at resection were sequenced with Ion Ampliseq transcriptome yielding expression values for 12,635 genes. Differential expression analysis was performed across response groups (16 Responders, 34 Non-Responders) as defined by Pathological Complete Response and over treatment time to identify significantly differentially expressed genes, pathways and markers indicative of response status.

Results: An on-treatment marker for response was identified (AAGAB), which resulted in a testing accuracy of 100% and a validation accuracy of 78% in the I-SPY 1 Trial. AAGAB was predictive of long term survival ($p = 0.048$ testing, $p = 0.031$ validation) in both chemotherapy cohorts at the same expression level as defined for treatment response. The single gene on-treatment biomarker, AAGAB proves more performant than established prognostic tests, Mammaprint (Edinburgh NEO trial, pre-treatment 61%, on-treatment 63%. I-SPY 1 trial, pre-treatment 60%, on-treatment 66%) and Pam50 RORS (neo trial pre-treatment 50%, on treatment 58%, Magbanua trial pre-treatment 56%, on-treatment 64%)

Conclusion: Changes in gene expression of on-treatment chemotherapy breast cancer resulted in the identification of a novel gene marker that was as effective in predicting prognostic status as established prognostic tests. These results support the use of on-treatment testing in breast cancer to improve the accuracy of tumour response prediction.
Circulating lymphocytes and pathologic complete response rate among patients with early stage triple negative breast cancer treated with neoadjuvant chemotherapy

Sarah M Talamantes¹, Ricardo LB Costa², Alfred Rademaker¹ and Cesar A Santa-Maria³. ¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Moffitt Cancer Center, Tampa, FL and ³Johns Hopkins University, Baltimore, MD.

Background: Chemotherapy can affect circulating immune cells. Low lymphocyte counts have been associated with worse prognosis in many cancers and inferior responses to immune checkpoint therapy. The effects of neoadjuvant chemotherapy on the immune system and its association with clinical outcomes in breast cancer is not well described.

Methods: A database was constructed of patients diagnosed with early stage triple negative breast cancer (TNBC) treated with neoadjuvant chemotherapy. Clinicopathologic information was extracted from the local electronic tumor registry or by chart review. Circulating lymphocyte and monocyte counts were assessed at the time of diagnosis, after neoadjuvant chemotherapy, and prior to surgery (all values in K/cu mm). These were correlated with clinicopathologic data, pathologic complete response (pCR) rates, and disease free survival (DFS) using rank sum test and Spearman correlation, t-test and log rank test, respectively.

Results: From 2000-2015, 426 patients with breast cancer treated with neoadjuvant chemotherapy were sequentially identified by an institutional electronic database. After excluding those who did not actually receive neoadjuvant therapy, were a subtype other than TNBC, and had missing receptor status or blood counts, 95 patients met eligibility for analysis. The median age of patients was 50 (range 26-79); 63 (66%) patients were treated with anthracyclines plus taxanes, 29 (31%) platinum-based chemotherapy, 2 (2%) with only anthracyclines, and 1 (1%) with only taxanes; 32 (34%) patients achieved a pCR; and 33 (35%) patients had recurrence events. Median follow up time was 47 months (range 13-123). No significant associations were found between pCR and changes in lymphocyte or monocyte count (mean lymphocyte reduction 0.74 in those with no-pCR versus 0.60 in those with pCR, p=0.30; mean monocyte reduction 0.0 in those with no-pCR versus 0.016 in those with pCR, p=0.78). There was no correlation between changes in lymphocytes or monocytes with DFS. Baseline lymphocytes or monocytes also did not correlate with pCR or DFS. Notably, there was a correlation between monocytes after neoadjuvant chemotherapy and pCR (mean monocyte level was 0.56 in those with no-pCR versus 0.46 in those with pCR, p=0.049) and DFS (median DFS in highest monocyte quartile 30 months versus in lowest quartile 107 months, p=0.022).

Conclusions: Our results suggest that transient lymphopenia from chemotherapy is not associated with clinical outcomes. However, we observed lower absolute circulating monocyte counts after neoadjuvant chemotherapy were associated with better clinical outcomes. Further research assessing the role of circulating immune cells is required to understand the effects of neoadjuvant chemotherapy on clinical outcomes, which may help inform immunotherapy-based strategies.
Development of pan-cancer transcriptional signatures that predict chemosensitivity

Jason D Wells¹ and Todd W Miller¹. ¹Norris Cotton Cancer Center, Dartmouth College, Lebanon, NH.

**Background:** Despite the increasing understanding of the molecular characteristics of cancer, chemotherapy success rates remain low for many cancer types. Studies have attempted to identify patient and tumor characteristics that predict sensitivity or resistance to different types of conventional chemotherapies, yet a concise model that predicts chemosensitivity based on gene expression signatures across cancer types remains to be formulated. We attempted to generate a pan-cancer chemosensitivity predictive model using publicly available data from multiple sources. Such a model may increase the likelihood of identifying the type of chemotherapy most likely to succeed for a given patient based on the gene expression signature of their tumor.

**Methods:** Data used to build the predictive model were obtained from the Genomics of Drug Sensitivity in Cancer (GDSC) database, consisting of gene expression profiles from 962 cancer cell lines via RNA sequencing (RNA-seq) and drug sensitivity profiles reported as ln(IC50). Predictive gene signatures were generated using a cross-validated generalized linear model (leave one out cross-validation) using elasticnet penalization parameters. Models were generated for each individual drug tested by the GDSC cohort, as well as different classes of chemotherapeutics (platinum agents, topoisomerase inhibitors, mustard agents, antibiotics and anti-fungals, anti-metabolites, and taxanes). Accuracy of the models was determined using normalized mean square error (nRMSE). Models were then validated using publicly available data from Cancer Cell Line Encyclopedia (CCLE), NCI-60, and the Patient-Derived Xenograft (PDX) Clinical Trial (PCT) database. Models were further validated using human tumor datasets available via the Gene Expression Omnibus (GEO). As the training data used to generate the models were from RNA-seq, and some of the testing and validation data were generated using microarray technology, feature-specific quantile normalization was used to enable cross-platform analyses.

**Results:** For most single-drug gene signatures, accuracy measured by nRMSE ranged from 0.10-0.20, which suggests that for any given model the root mean squared error is 10-20% of the range of actual ln(IC50) in the tested data. Chemotherapy class-level models yielded slightly less accuracy, with nRMSE ranging from 0.15-0.25 for most classes. When considering how well the models predicted chemosensitivity within cancer types, accuracy was improved in some cancer types (e.g., lung cancer and head and neck cancer), with more heterogeneous cancer types (e.g., breast cancer) giving less accuracy.

**Conclusions:** Our results show that the models generated can predict chemosensitivity across cancer types with clinical useful levels of accuracy, with some cancer types resulting in a high rate of accuracy across several classes of chemotherapy. The inclusion of future datasets, particularly from those cancer types in which chemosensitivity has been difficult to predict, may provide opportunities to strengthen model accuracy as well as decrease the numbers of genes needed to assess chemosensitivity.
Immunosuppressive profiles in liquid biopsy predict response to neoadjuvant chemotherapy in triple negative breast cancer

BACKGROUND
Despite the recent advances in triple negative breast cancer (TNBC) stratification, TNBC is still a highly heterogeneous subtype that clusters distinct molecular and genetic alterations with diverse responses to neoadjuvant chemotherapy (NAC). Molecular profiling after NAC has unraveled a group of actionable targets in residual TNBC that supports the implementation of targeted therapies in a personalized manner. However, unresponsive or poor NAC responders after first line treatment are committed to poorer outcome. Therefore, early identification of poor NAC responders is essential to select patients that may benefit from alternative therapies, including initial tumor resection before chemotherapy.

MATERIAL AND METHODS
We have conducted a study on 37 non-metastatic TNBC patients at La Fe Hospital that were homogeneously treated with anthracycline and cyclophosphamide followed by paclitaxel. Tissue and blood-derived biopsies were obtained at diagnosis. Metabolites and miRNA exosomes in plasma were analyzed by ultra-performance liquid chromatography-electrospray ionization tandem mass spectrometric and by miRNA 3.0 arrays (Affymetrix) respectively. Immunosuppressive subpopulations of cells were quantified by flow cytometry with specific markers. IDO1 in situ expression was assessed by immunohistochemistry on the tissue biopsies.

RESULTS
In order to identify blood-derived liquid biopsy NAC predictor biomarkers in TNBC we have studied blood circulating cells and molecules known for their immunomodulation capacity and found that eMDSC and a profile of tryptophan-derived metabolites predict NAC response. In addition, we identified a circulating exosome miRNA profile that identifies poor NAC responders. Interestingly, this profile of miRNAs target pathways involved in the immune response. IDO1 expression in the tumor inversely correlated with circulating tryptophan levels and directly associated with eMDSC. We also observed a trend correlating IDO1 expression levels with poorer response.

CONCLUSIONS
Our results strongly support the role of immunosuppression in TNBC poor responders and establish an easy and non-invasive tool for the early identification of poor NAC responders, opening the possibility to use alternative strategies.

A novel biodynamic imaging assay predicts success or failure of neoadjuvant chemotherapy in breast cancer patients

Eric Whitacre1, Eric Manahan2, William Burak3, Travis Morgan4, Ran An4 and David Loesch4. 1Breast Center of Southern Arizona, Tucson, AZ; 2Dalton Surgical Group, Dalton, GA; 3Memorial Health University Medical Center, Savannah, GA and 4Animated Dynamics, Inc., Indianapolis, IN.

Background: Use of neoadjuvant chemotherapy (NAC) in breast cancer patients has increased significantly over the past decade. The clinical benefits of NAC, including potential to downstage disease, facilitation of breast conserving surgery and use of pathologic response as a prognostic marker, are well established. However, with multiple regimens approved and recommended for NAC, choosing the optimal therapy for individual patients remains a challenge. Biodynamic imaging (BI), a novel technology that captures cellular motility in living tissue via Doppler spectroscopy, could be used ex-vivo to prospectively evaluate the efficacy of systemic therapies in patient tumor samples prior to treatment. This study aimed to determine whether BI could accurately predict likelihood of response to NAC in breast cancer patients.

Methods: Fresh core biopsies were obtained from 84 patients prospectively enrolled in an IRB-approved clinical trial at 5 institutions between 1/5/17 and 8/3/2018. Patient tumor tissue was collected at time of routine diagnostic biopsy and sent to a central laboratory where it was divided into intact tumor fragments measuring approximately 1mm in diameter. Fragments were placed into 96 well plates and imaged using the BI assay (Onco4D™), while being challenged by various cytotoxic agents for up to 20 hours. Cellular characteristics and motility signatures were evaluated and compared to pathologic NAC response established upon surgical resection (mastectomy or lumpectomy).

Results: At the time of this analysis, centrally-confirmed pathologic response data were available for 17 patients treated with doxorubicin/cyclophosphamide ± taxane (AC). Pathologic outcomes are pending for an additional 8 AC patients. The remainder of the 84 patients initially enrolled in the study either did not receive NAC (n=10), have not yet selected a course of therapy (n=12), or received NAC regimens other than AC (n=37). Of the 17 currently evaluable AC-treated patients, 4 had triple negative (TN) disease, 12 were hormone receptor positive, and 1 hormone receptor negative patient showed equivocal HER2 results. Two of the TN patients were known to harbor pathogenic BRCA1 mutations and received carboplatin in addition to AC. Seven of 17 patients (40%) displayed resistance to AC (2 with progressive and 5 with stable disease) while 10 experienced objective response (8 partial and 2 complete response). A multilinear regression model using 10 BI markers accurately classified 16 of 17 patients (94%) while producing 1 false prediction of partial response for a patient with stable disease clinically (R-squared=0.9994, p<.0001). The positive predictive and negative predictive values of BI to AC response were 100% and 91%, respectively.

Conclusion: BI was able to accurately predict patient response to neoadjuvant AC, demonstrating the potential for the platform to support personalized patient therapy. This clinical trial is ongoing and will report out results for TC (docetaxel/cyclophosphamide), TCHP (docetaxel/carboplatin/trastuzumab + pertuzumab), and additional AC patients as outcome data are accrued.
Risk of ischemic heart disease after adjuvant radiotherapy for breast cancer

Anna-Karin Wennstig¹, Charlotte Wadsten¹, Hans Garmo², Fredrik Wärnberg³, Lars Holmberg³, Carl Blomqvist⁴, Greger Nilsson⁵ and Malin Sund¹. ¹Umeå University, Umeå, Sweden; ²Regional Cancer Center, Uppsala University/ Uppsala University Hospital, Uppsala, Uppsala, Sweden; ³Uppsala University, Uppsala, Uppsala, Sweden; ⁴Örebro University Hospital, Örebro, Örebro, Sweden and ⁵Section of Experimental and Clinical Oncology, Uppsala University, University Hospital, Uppsala, Uppsala, Sweden.

**Background:** Adjuvant radiotherapy (RT) for breast cancer (BC) substantially reduces BC mortality and loco-regional recurrences, but incidental radiation exposure to the heart is associated with ischemic heart disease (IHD). We examined the incidence of IHD in a large population-based cohort of women with BC.

**Patients and methods:** The Breast Cancer DataBase Sweden (BCBase) cohort includes all women diagnosed with BC in three of Sweden's six health care regions from 1992-2012 with five age-matched controls without a history of BC for each BC case. A total of 60217 women with BC were included in the BC cohort, and 300791 women without BC in the comparison cohort. Through linkage with a number of population-based registries, information concerning comorbidity, socioeconomic status, and incidence of IHD was obtained. Cox proportional hazards regression analyses were performed to estimate risk of IHD for women with BC compared to the comparison cohort, and for women with left-sided BC compared to right-sided BC. The analyses were adjusted for previous IHD, comorbidity, and socioeconomic status. The BC cohort was stratified by RT, endocrine therapy, and chemotherapy.

**Results:** The median follow-up time was 8.1 years. The risk of IHD was significantly lower for the BC cohort compared to the comparison cohort, with a hazard ratio (HR) of 0.91 (95% CI 0.88-0.95). The HR’s for IHD was even lower in women with BC selected for adjuvant treatment with RT, endocrine therapy or chemotherapy. When women with left-sided BC were compared to right-sided BC an increased HR for IHD of 1.09 (95% CI 1.01-1.17) was seen for the whole cohort, and of 1.18 (95% CI 1.06-1.31) in women receiving RT. When RT was stratified for pathological nodal involvement, a HR of 1.22 (95% CI 0.98-1.51) for women with 1 to 3 pathological lymph nodes was seen, and of 1.72 (95% CI 1.19-2.48) for women with more than 4 pathological lymph nodes, probably reflecting more extensive RT. When RT was combined with other adjuvant treatments, a HR for IHD of 1.24 (95% CI 1.09-1.42) was seen for endocrine therapy, of 1.28 (95% CI 0.98-1.67) for chemotherapy, and of 1.35 (95% CI 0.95-1.92) for endocrine therapy and chemotherapy combined in left-sided BC compared to right-sided BC, suggesting an additive effect to RT on the risk of IHD.

**Conclusion:** The results show a persisting increase in risk of IHD in left-sided RT with contemporary radiation techniques and radiation targets. The increase in risk of IHD in women with left-sided RT seen when endocrine therapy and chemotherapy were added to RT suggests an additive effect on the risk of radiation-induced IHD. Long-term side effects of adjuvant treatment have to be taken into consideration in RT planning to ensure health and quality of life for BC survivors. The results are an incentive to conduct further research concerning dose constraints to the coronary arteries, and of implementation of RT techniques that can lower cardiac radiation doses. Selection of patients to active treatment, and a healthier lifestyle in BC survivors may explain the findings of lower risk of IHD in the BC cohort compared to the comparison cohort.
Intraoperative radiotherapy outcomes in early-stage breast cancer: A study in elderly Canadian women

Maryam Elmi¹, Alex Tigert², Jaime Escallon³, Brandon Zagorski⁴, Wey Leong³, Marie Vranic³, Anthony Fyles³, Alex Vitkin³, Tulin Cil³ and David McCready³. ¹UT Texas Health San Antonio, San Antonio, TX; ²Faculty of Medicine, University of Toronto, Toronto, ON, Canada; ³Princess Margaret Cancer Center, University Health Network, Toroto, ON, Canada and ⁴Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada.

**Objective.** Breast-conserving therapy with external beam radiotherapy (EBRT) is currently the standard of care for women with early breast cancer. Our aim was to determine if early-stage breast cancers treated with lumpectomy and primary intraoperative radiotherapy (IORT) have comparable local recurrence rates. This is the first study examining the Canadian experience with IORT.

**Methods.** Patients who underwent breast-conserving therapy with pre-pathology IORT between 2007-2017 were retrospectively identified. The primary outcome measure was ipsilateral breast tumor recurrence (IBRT). A time to event analysis was performed; Kaplan-Meier estimates report the fraction of patients living free of recurrence. Secondary outcomes included acute and chronic wound complications.

**Results.** 106 patients with a median age of 70 (IQR 65-75) were included. Median follow-up was 33 months. The majority of patients had screen-detected (94.3%), estrogen-receptor positive (96.2%), HER2neu negative (93.4%), invasive ductal carcinomas (92.5%). Only 50 (47.6%) were prescribed adjuvant endocrine blockade. IBTR occurred in 5 (4.7%) patients. Five and ten-year local recurrence-free rates were 0.95 and 0.81, respectively. The superficial skin infection rate was 9.4%. Acute symptomatic seromas occurred in 23 (21.7%), while only 10 (9.4%) persisted chronically.

**Conclusion.** In this cohort of Canadian post-menopausal women treated with breast-conserving surgery and IORT, the IBTR approached 5%. Despite selection of low-risk patients, the local recurrence rate is higher than what is reported in the literature with EBRT. The low rates of prescribed adjuvant systemic therapy may have contributed to this outcome.
Purpose: Consensus guidelines for regional nodal irradiation (RNI)/postmastectomy radiation (PMRT) clinical target volumes (CTV) have slight variations amongst leading national organizations. In the US, the Radiation Therapy Oncology Group (RTOG) defines the caudal edge of the supraclavicular (SCV) CTV as the junction of the brachiocephalic and axillary vessels while the internal mammary nodal (IMN) CTV starts at the superior aspect of the medial first rib. This leaves an anatomical gap between the two target volumes. The European Society of Radiation Oncology (ESTRO) does not recommend leaving a gap between the SCV CTV and IMN CTV. We set to analyze radiation dose and patterns of failure in this region.

Materials and Methods: We identified consecutive patients treated with RNI/PMRT at our institution from 2013-2016. Patients with metastatic or recurrent disease were excluded. All patients received 50 Gy/25 fractions to the breast/chestwall+regional nodes (including IMN PTV) +/- boost to the lumpectomy cavity/mastectomy scar using 3D conformal radiotherapy (3DCRT) or intensity modulated radiation therapy (IMRT). We retrospectively contoured the vessels from one slice below the caudal border of the SCV PTV contour to one slice cranial to the first IMN PTV contour. We calculated the mean dose and the relative V40Gy, V45Gy, and V47.5Gy of the gap region. A gap failure was defined as a first recurrence in this region with or without simultaneous loco-regional recurrence (LRR) or distant metastases (DM). We used the cumulative incidence method to calculate the gap recurrence rate with DM, LRR, and death, as competing risks.

Results: 230 patients were included with median age 52 years, predominantly stage III disease (60%), and most treated with preoperative (51%) or postoperative (41%) systemic therapy. Breast cancer subtype was ER+/HER2- in 138 patients, triple negative in 44 patients, and HER2+ in 48 patients. The median (IQR) mean dose, V40Gy, V45Gy, and V47.5 Gy in the gap region were: 20.3 Gy (14.8-26.2 Gy), 6% (1.3%-20.0%), 0.6% (0%-7.0%), and 0% (0%-1.3%). The mean dose to the gap region was slightly higher in patients treated with IMRT (N=68) compared to 3DCRT (N=162): 25.3 Gy (SD 7.5 Gy) vs. 19.5 Gy (SD 8.0 Gy), p<0.0001. With median follow-up of 32 months, there were 2 recurrences in the gap region, both of which occurred with simultaneous distant metastases. No patients had isolated recurrences in the gap region. The 3-year cumulative incidence of recurrence in the gap region was 0.8%. The predominant pattern of failure was DM (N=31) with a 3-year rate of 14.4% followed by LRR (N=6, 4 with simultaneous distant metastases) with a 3-year rate of 3.1%.

Conclusion: In a clinical practice in which we routinely contour and treat the IMN PTV and SCV PTV with a gap region between those two volumes, we found that the mean radiation dose to this region is low, at about 50% or less compared to the prescription dose. Despite this, recurrences in this region are exceedingly uncommon and have not yet occurred in the absence of simultaneous DM. While the follow-up is limited, these data support the current guidelines of not routinely targeting this region.
Analysis of radiation dose to the shoulder by treatment technique and correlation with patient reported outcomes in patients receiving regional nodal irradiation

Jose G Bazan¹, Dominic Dicostanzo¹, Karen Hock¹, Erin Healy¹, Sasha Beyer¹ and Julia R White¹. ¹The Ohio State University, Columbus, OH.

Background: Shoulder/arm morbidity is a late complication of breast cancer treatment. Postmastectomy radiation therapy (PMRT)/regional nodal irradiation (RNI) increases dose to the muscles and soft tissues of the shoulder and upper neck and back. Most patients are treated with 3D conformal radiation therapy (3DCRT) or Intensity modulated radiation therapy (IMRT). Here, we set to analyze the impact of 3DCRT vs. IMRT on radiation dose to the shoulder, and to retrospectively explore the relationship of treatment technique on long term patient-reported outcomes in the subset of patient who had completed the quick Disabilities of the Arm, Shoulder, and Hand (q-DASH) questionnaire.

Materials/Methods: We identified consecutive patients in our department treated with PMRT/RNI for curative intent from 2013-2016. We excluded patients treated for recurrent disease, those with metastatic disease, and those with unresected disease in the supraclavicular (SCV) fossa and/or axillary apex requiring a radiation boost to that area. We contoured the shoulder as all of the muscles/soft tissue/bone from 2 cm above the ipsilateral SCV planning target volume (PTV) to the cranial aspect of the breast or chestwall PTV. No planning constraints were set for the shoulder since this was retrospectively contoured. We used the dose volume histogram to determine the volume of shoulder receiving at least 5 Gy, 10 Gy,...,50 Gy (V5-V50, respectively). We identified patients that completed a q-DASH questionnaire ≥6 months from the end of PMRT/RNI. Descriptive statistics were used to summarize the shoulder dose and q-DASH values. Differences between groups were assessed by the t-test or chi-square test with p<0.05 considered significant.

Results: We found 237 patients treated with PMRT/RNI with median age of 52 y (IQR 44-60 y), 75% treated with mastectomy, 85% had axillary lymph node dissection (ALND), median of 18 nodes removed (IQR 12-26). All patients received 50 Gy/25 fractions. A total of 68 patients (28.7%) were treated with IMRT. IMRT significantly reduced the V20-V50 to the shoulder vs. 3DCRT (e.g., V45Gy=21.7 mL vs. 208.4 mL, p<0.0001). Of the 237 patients, 66 had completed a q-DASH at least 6 months from the end of radiation therapy (median, 14.5 months). Patients that completed the q-DASH vs. not were similar in age (p=0.29), number of nodes removed (p=0.17), use of ALND (p=0.13), use of chemotherapy (p=0.49) and use of mastectomy (p=0.22). The median (IQR) and mean (SD) q-DASH were 20.5 (6.8-38.6) and 24.3 (20.2) for all patients; 20.5 (9.1-38.6) and 24.1 (24.2) for the 53 mastectomy patients; 18.2 (4.5-45.5) and 25.2 (24.2) for the 13 lumpectomy patients. Most patients (N=49) were treated with 3DCRT. Compared to patients treated with 3DCRT, IMRT patients had a trend towards lower q-DASH mean scores: 16.9 vs. 26.9, p=0.077.

Conclusion: In summary, we found that IMRT reduces radiation dose to the shoulder and is associated with a trend towards reduced q-DASH scores at least 6 months after PMRT/RNI in a subset of our cohort. These results support prospective evaluation of IMRT as a technique to reduce shoulder morbidity in breast cancer patients receiving PMRT/RNI.
Fractionation patterns in adjuvant breast radiotherapy in Ontario, Canada from 2009 to 2015

Edward Chow1, Stephanie Chan1, Zhan Yao2, Rinku Sutradhar2, Justin Lee1, Bo A Wan1 and Lawrence Paszat1,2. 1Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada and 2Institute for Clinical Evaluative Sciences, Toronto, ON, Canada.

Purpose: To report the patterns of use of hypofractionated radiotherapy (HFRT) (≤16 fractions) in breast cancer and ductal carcinoma in situ (DCIS) patients in Ontario, Canada from 2009 to 2015 and identify factors related to HFRT use.

Methods: A retrospective cohort study of Ontario women diagnosed with breast cancer or DCIS followed by adjuvant breast or chest wall radiation (RT) from 2009 to 2015 was conducted using data from the Institute for Clinical Evaluative Sciences (ICES). Logistic regression models were used to identify factors associated with HFRT use. Physician was included as a random effect. To calculate the potential amount of time that could be saved if all patients were to receive 16 fractions of HFRT, the number of extra RT treatments after the 16th visit was multiplied by the median amount of time spent to treat one patient at our cancer centre (8.76 minutes). This time was found with Sunnybrook Health Sciences Centre data collected from October 2017 to March 2018 (n=523) and represents the amount of time from when a patient enters the RT unit for treatment setup, until the RT beam is turned off.

Results: A total of 42,072 patients were included. Most patients were aged between 50 and 69 years old (56.7%) with stage I or II breast cancer (74.6%) and had breast conserving surgery (BCS) (76.9%). Half previously received chemotherapy and 7.9% were DCIS patients. Use of sequential boost, simultaneous boost, and regional nodal RT was 17.2%, 3.1%, and 31.7% respectively. Institutional variation in HFRT use ranged from 27.5% to 71.6%. HFRT use has increased in all patient populations over the study period. HFRT use was more common in breast cancer and DCIS patients with BCS than in chest wall and nodal RT.

Trends in the use of HFRT (%) from 2009 to 2015 for DCIS and breast cancer patients in Ontario.

BCS: breast conserving surgery, RT: radiation treatment

Simultaneous boost (OR=0.09), nodal RT (OR=0.08), previous chemotherapy (OR=0.7), stage 0, II, and III breast cancer (OR=0.06 relative to stage I), were correlated with less HFRT use. Older age, later year of diagnosis, sequential boost (OR=0.09), BCS and no surgery (OR=1.2, 1.5 relative to mastectomy) were correlated with higher HFRT use. Institution was significantly correlated to HFRT use. The variance estimate for the physician random effect was 0.33 (p<0.0001). For breast cancer patients with BCS and breast RT specifically, 62,396 extra visits occurred from 2009 to 2015, corresponding to ~9100 hours of treatment if all patients received HFRT. For the entire patient population, a total of 190,726 extra visits occurred or ~27,900 hours.

Conclusions: HFRT use in Ontario has increased over time for all patient populations, and reflects the current evidence supporting HFRT in different patient populations, with lower HFRT use seen in chest wall and nodal RT and higher HFRT use in early-stage breast cancer patients with BCS.
TOxicities of Locoregional Radiotherapy Associated with Bevacizumab in patients with non-metastatic breast cancer (TOLERAB): Final long-term evaluation

Alice Clément-Zhao¹, Marie-Laure Tanguy¹, Paul Cottu¹, Brigitte De La Lande¹, Patrick Bontemps⁴, Claire Lemanski³, Pierre Baumann⁵, Christelle Levy³, Karine Peignaux⁶, Agnès Reynaud-Bougnoux⁷, Aline Gobillion¹ and Youlia Kirova¹. ¹Institut Curie, Paris, France; ²Institut Régional du Cancer de Montpellier, Montpellier, France; ³Centre François Baclesse, Caen, France; ⁴CHU Jean Minjoz, Besançon, France; ⁵Centre d'Oncologie de Gentilly, Nancy, France; ⁶Centre Georges-François Leclerc, Dijon, France and ⁷CHU Tours, Tours, France.

Background and Purpose: Recent phase 3 clinical trials have evaluated the addition of bevacizumab (B) to standard chemotherapy in the treatment of patients with non-metastatic breast cancer. But few data are available about the tolerance of B with locoregional radiation therapy (RT). The objective was to evaluate the 5 years late toxicities of the concurrent B and RT in non-metastatic breast cancer.

Material and methods: This is a multicenter prospective study including non-metastatic breast cancer patients enrolled in phase 3 clinical trials evaluating B with concurrent RT (BEATRICE, BETH, BEVERLY 1, BEVERLY 2) versus RT alone. All patients received neo-adjuvant or adjuvant chemotherapy and normo-fractionated breast or chest wall RT, with or without regional lymph nodes RT. B was administrated as an equivalent of 5 mg/kg every week for 1 year. The safety profile (using the Common Terminology Criteria for Adverse Events version 3.0) was evaluated at 1, 3 and 5 years after the completion of radiotherapy.

Results: From October 2007 to January 2012, 151 patients totally included. Median follow-up was 60 months (36-84) and 5 years late toxicities were available for 104 patients (46 with B and RT, 58 with RT alone). Median age was 51 (22-81). 61% of patients received regional lymph nodes RT. The majority of tumor was triple negative (65.6%), tumor size <2cm (50%) and nodal status negative (63.8%). Median total dose of B was 15000 mg (13200 – 18550) and median duration was 11.2 months (11-12.6). No grade ≥3 toxicity was observed. Only 16 patients had grade 1-2 toxicities (8 treated with B and RT, 8 with RT alone): n=4 (3.8%) had grade 1 pain, n=5 (4.8%) had grade 1-2 fibrosis, n=1 (1%) had grade 2 telangiectasia and n=5 (4.8%) had grade 1-2 lymphoedema. No significant difference between the 2 arms was observed. One patient of 46 evaluated had Left Ventricular Ejection Fraction inferior to 50%. At 5 years, overall survival was 93.8%, disease free-survival 89% and locoregional free-survival 93.1 %.

Conclusion: Concurrent B and locoregional RT provides acceptable 5-years toxicities in patients with non-metastatic breast cancer. No grade ≥3 toxicity was observed.
Conservative breast reconstruction: Outcomes of 146 consecutive cases of prepectoral, subcutaneous implant-based breast reconstruction in a single-Institution series

Icro Meattini¹, Marco Bernini¹, Calogero Saieva², Isacco Desideri¹, Vieri Scotti¹, Viola Salvestrini¹, Luca Visani¹, Matteo Mariotti¹, Camilla Delli Paoli¹, Emanuela Olmetto¹, Virginia Maragna¹, Lorenzo Orzalesi¹, Luis Sanchez¹, Jacopo Nori¹, Simonetta Bianchi¹ and Lorenzo Livi¹. ¹Azienda Ospedaliero-Universitaria Careggi, University of Florence, Florence, Italy and ²Istituto per lo Studio, la Prevenzione e la Rete Oncologica (ISPRO), Florence, Italy.

Aims. To evaluate acute and late toxicity-related factors among breast cancer (BC) patients who underwent prepectoral breast reconstruction (BR).

Methods. We performed a retrospective analysis of BC patients who underwent therapeutic or prophylactic mastectomy from October 2012 to May 2016 at our Center. We recorded individual patient-related features (i.e. age, body mass index [BMI], smoke-history, comorbidity, BRCA-carrier), BC-related treatments characteristics (i.e. axillary surgery, adjuvant radiotherapy [RT], adjuvant chemotherapy, primary systemic therapy [PST], endocrine therapy, and use of trastuzumab). Toxicity profile was evaluated in terms of complications related to BR; we recorded acute and late toxicity data and prosthesis/implant explant rate.

Results. We analyzed 146 consecutive BC patients treated with subcutaneous BR, 117 therapeutic and 29 prophylactic mastectomies. Thirty-seven patients received postmastectomy RT. Significant factors related to acute toxicity were: previous RT (34.5% [RT] vs 8.5% [no RT]; p=0.001), BMI (31.3% [BMI ≥25] vs 8.8% [<25]; p=0.003), previous breast surgery (22.2% [surgery] vs 8.7% [no surgery]; p=0.027), and diabetes (100% [diabetes] vs 11.9% [no diabetes]; p=0.002). Factors significantly correlated to implant/prosthesis explant were: current or previous smoking exposition (13.8% [smokers] vs 2.6% [non-smokers]; p=0.029) and PST (18.8% [PST] vs 3.5% [no PST]; p=0.022); axillary lymph node dissection (ALND) was significantly related to late toxicity (5.7% [ALND] vs 0%; p=0.04). At a 3-year median follow up, three deaths, five locoregional recurrences (LRR), and fourteen distant metastasis (DM) occurred among 117 patients treated by therapeutic mastectomy. Overall survival was 78.1%, LRR free-survival was 95%, and DM free-survival was 71.6%. Postmastectomy RT was not significantly related to acute, late toxicity, and explant occurrence.

Conclusions. In our experience prepectoral subcutaneous implant-based BR is a safe and effective approach, with low rates of acute toxicity. Major risk factors were evidenced for patients previously treated with RT or surgery, and in case of diabetes or BMI ≥25; postmastectomy RT seems not to be related to higher rate of toxicity. ALND seems to be the only factor significantly related to late toxicity. PST, and smoking exposition were significantly associated with higher rate of implant/prosthesis explant. However, further investigations and mature follow-up are warranted to confirm these encouraging results.
The role of neo-bioscore staging system in guiding the optimal strategies for regional nodes irradiation following primary systemic treatment in breast cancer patients with cN1 and ypN0-1

Lu Cao¹ and Jia-Yi Chen¹. ¹Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Purpose: Following primary systemic treatment (PST), the optimal strategies for regional nodal irradiation (RNI) are currently under active investigation, especially in patients with pretreatment cN1 and posttreatment ypN0-1. The Neo-Bioscore staging system has showed promising prospect in assessing prognosis after PST. In this analysis, we evaluate the role of Neo-Bioscore staging system in guiding RNI following PST in patients with cN1 and ypN0-1.

Methods and Materials: Continuous women with cN1 pretreatment and who received PST with ypN0 or ypN1 posttreatment between 2009 and 2014 were retrospectively reviewed. According to the report by Mittendorf et al, the Neo-Bioscore staging system is on the basis of pretreatment clinical stage, posttreatment pathologic stage, estrogen receptor (ER) status, HER2 status and grade stage, and assigned and summed points for each factor as shown in

A pathologic complete response (pCR) was defined as no invasive disease in the breast or regional lymph nodes after surgery. The curves for survival were generated using the Kaplan-Meier method and compared using the Log-rank test.

Results: One hundred and sixty-three patients were enrolled in this study, of them 18 patients received breast conserving surgery. Of the 163 patients, 119 (73%) received RNI. At surgery, 36 patients (22.1%) achieved pCR, while 89 patients (54.6%) achieved ypN0. The median follow-up was 59.4 months (range: 16-106). In the whole cohort, RNI was associated with non-significant improved outcomes, with a 5-year locoregional recurrence free survival (LRRFS) rate of 98.6% vs. 95.7% (P=0.393), a regional
recurrence free survival (RRFS) rate of 98% vs. 97.7% (P=0.865), a 5-year distant metastasis free survival (DMFS) rate of 91.6% vs. 83.4% (P=0.052), a 5-year any first recurrence free survival (RFS) rate of 90.9% vs. 87.4% (P=0.43), and a 5-year overall survival (OS) rate of 98% vs. 91.9% (P=0.097) in the RNI and non-RNI group, respectively. In the subgroup of patients with Neo-Bioscore score of 1 to 3, RNI significantly increased the 5-year DMFS rate of 97% vs. 76.9% (P=0.002), 5-year RFS rate of 95.5% vs. 76.9% (P=0.007) and 5-year OS rate of 100% vs. 89.2% (P=0.005). However, no significant difference in outcomes was found between RNI and non-RNI group in patients with Neo-Bioscore score of 4 to 6. Among patients who not achieved pCR and those with ypN1, RNI significantly increased DMFS (both P<0.05).

Conclusions: Not all patients with cN1 and ypN0-1 could significantly benefit from RNI following PST, those with low Neo-Bioscore score were likely to benefit more.
Dosimetric analysis of the pattern of local recurrence in breast cancer patients undergoing breast reconstruction and post-mastectomy radiotherapy

Isacco Desideri¹, Icro Meattini¹, Carlotta Becherini¹, Giulio Francolini¹, Vieri Scotti¹, Emanuela Olmetto¹, Marco Perna¹, Juljana Topulli¹ and Lorenzo Livi¹. ¹University of Florence, Florence, Italy.

Background
This study aims to identify spatial and dosimetric patterns of breast cancer relapse in a mono-institutional large series of patients treated with mastectomy and various forms of breast reconstruction.

Material and Methods
We retrospectively reviewed 196 patients with Stage II-III breast cancer treated with modified radical mastectomy between 1995 and 2016 at the Radiotherapy Department of Careggi Hospital, Florence. All patients performed Skin-sparing mastectomy or nipple-sparing mastectomy with immediate or delayed breast reconstruction and subsequently received post-mastectomy radiotherapy (PMRT). Systemic therapy was prescribed as per local and international guidelines both in neoadjuvant and adjuvant setting. All patients were treated with 3DCRT technique. Diagnostic imaging (e.g. CT, MRI) obtained at recurrence were registered with the original planning computed tomography (pCT) for the dosimetric analysis. Recurrence gross tumor volume (rGTV) were delineated and co-registered with pCT. All rGTV were compared dosimetrically to planned dose and spatially with planning target volumes. Locoregional recurrence (LR) were divided in three categories relative to the high dose region, 95% of prescription dose (D95%). We defined “in field LR” those with more than 90% of their volume within D95% region, “marginal LR” when recurrence volume was between 20 and 90% within D95% and “out-field LR” those with less than 20% of their volume D95%.

Results
The median age was 49 years (range, 26 - 83 years). 163 women (83 %) were classified as stage III; 118 women (60 %) had more than three positive axillary nodes. The majority of lesions were estrogen receptor positive (75 %), grade 3 (52%) ,with the presence of LVI (60 %). Adjuvant RT at chest wall were performed in all patients, most of whom underwent a RT of chest wall +infra- supraclavicular nodes (71%). Prescribed RT dose was 50 Gy in 25 fractions. With a median follow-up of 60 months (range, 12-240 months), 22 (11%) patients experienced a locoregional relapse: 10 patients in the chest wall; 7 in ipsilateral axillary region +/- chest wall; 3 in internal mammary nodes +/- chest wall; one locoregional relapse was observed in the supraclavicular nodes. Most of relapses were G3 (75%) with documented LVI (79%). The topographic analysis of the local failure patterns showed: thirteen (59 %) were “in-field LR”; 9 (41%) were “out-field LR”. For the spatial analysis, all relapses on the chest wall were observed above the breast tissue expander or mammary prosthesis. Free time from recurrence disease was 30 months (range 5-86 months).

Conclusion
This study suggests that chest wall recurrences are rare after PMRT and are related to biologic aggressiveness of the disease than to inadequate irradiation of target volumes. Prospective studies are warranted to evaluate the relationship between treatment volumes and patterns of recurrences in order to refine new delineation guidelines for women undergoing PMRT and breast reconstruction.
Utilization patterns and temporal trends of internal mammary nodal irradiation (IMNI) at a tertiary cancer centre

Shagun Misra², Grace Lee¹, Manjula Maganti² and Christine Anne Koch¹². ¹Radiation Medicine Program, Princess Margaret Cancer Centre / University Health Network, Toronto, ON, Canada and ²University of Toronto, Toronto, ON, Canada.

Purpose: Despite data from multiple randomized trials, the role and uptake of internal mammary nodal irradiation (IMNI) is variable. This study was designed to quantify the rates and determinants of IMNI at a tertiary cancer centre.

Methods: Treatment records of consecutively treated breast cancer (BC) patients receiving adjuvant locoregional (LR) radiotherapy (RT) from January 1, 2012 to October 31, 2017 was studied. LR-RT and use of IMNI as a function of clinicopathological factors, use of deep inspiratory breath-hold (DIBH) and dosimetric parameters were retrieved. Patients were divided into two groups: Group 1 received LR-RT that included the IMN's, supraclavicular (SCLV) ± axillary regions, Group 2 received LR-RT directed only to the SCLV±axillary areas. For the purpose of utilization analysis and temporal trends, early(2012-2015) and late(2016-2017) cohorts were examined based on the year of RT delivery. To determine if the use of IMNI was dependent on BC risk, we defined 3 risk categories: 1) pT1/2, N0; 2) pT1/2, N1; and 3) pT3/4, N2/3 disease. Differences between the risk categories and groups were evaluated using chi-square/ Fisher’s and Mann Whitney test for categorical and continuous variables, respectively. Univariable and multivariable logistic regression analysis was done to determine factors associated with the receipt of IMNI.

Results: A total of 1566 patients met eligibility (Group 1=376; Group 2=1190). Of these patients, the percentage receiving LR-RT remained constant (17%) over the study period but the proportion of patients receiving IMNI increased significantly each year (p<0.0001), and was higher in the late vs. early treatment cohort (55% vs 8%, p<0.0001). On univariable analysis, younger age, LVI positivity, medial/central location, increasing stage, PR negativity, mastectomy, axillary dissection, receipt of chemotherapy and increasing number of positive nodes had higher odds of receiving IMNI. Radiation oncologists with < or ≥5 years of practice was predictive of IMNI (31.3% vs 20.5%, p<0.0001), staff having <5 years in practice being more likely to recommend IMNI. The distribution of patients in the different risk categories was similar between Groups 1 and 2 (p=0.097), and identified that the majority of patients receiving IMNI were in risk category 2 (83%). Further comparison of risk categories suggested that the odds of receiving IMNI was lower in risk category 3 vs. category 1 (p=0.033). On multivariable analysis, decreasing age (p=<0.001), medial quadrant (p=0.0026), PR negative (p=0.0011), mastectomy (p=0.0055), increasing nodal positivity (p<0.0001) and late RT cohort (p=0.001) had increased odds of IMNI. Overall use of DIBH was significantly higher in those receiving IMNI (45% vs 26%, p<0.0001). Mean heart (2.2 vs 1.7Gy, p<0.0001) and total lung doses (7.8 vs 6.6Gy, p<0.0001) were also significantly higher with IMNI.

Conclusion: There was a significant increase in utilization of IMNI from 2012 to 2017. Younger age, medial location, PR negativity and increasing number of positive nodes predicted for receipt of IMNI. Staff with <5 years in practice were more likely to recommend LR-RT that included the IMNs. The use of DIBH significantly increased with IMNI and allowed for acceptable dosimetric constraints.
Prophylactic application of SkinSafe film strips to the inframammary fold prevents moist desquamation during irradiation for breast cancer in a prospective trial

Daniel Garren¹, Brandon Le⁵, Ravi Vasireddy², Laurie Flynn⁴, Ken Forster³, Leib Malina⁶ and Yoel Dorfman². ¹Instituto Dr.Jaim Weizman, San Jose, Costa Rica; ²Landmark Cancer Center, Muskogee, OK; ³University of California, San Francisco, San Francisco, CA; ⁴Hillcrest Medical Center, Tulsa, OK; ⁵University of California, Los Angeles, Los Angeles, CA and ⁶Yavneh Academy, Dallas, TX.

Purpose: To investigate the effect of prophylactic use of SafeSkin films strips applied to the inframammary fold during whole breast or reconstructed breast irradiation to avoid moist desquamation to the inframammary fold.

Materials and Methods: Between November 15, 2016 and April 17, 2018, a total of 30 patients were recruited, with 29 patients contributing to analysis, and one patient with bilateral breast cancer. Areas of the breast treatment field not covered by the film were treated with physician's choice of cream, (80% Jean's Cream, 13% Aquafor, and 7% with no topical therapy). The treatment field was photographed weekly. SkinSafe strips were reapplied as needed, but were not applied if erythema was already observed in the inframammary fold. Severity of skin reaction was assessed using the RTOG scale.

Results: There was only one treatment interruption, against medical advice, due to axillary discomfort. One patient refused further trial participation after the first day. No short or long term side effects of film use were noted. Inframammary desquamation developed in only one patient, who tried to replicate the increased comfort of her inframammary tape with adhesive bandages when her tape came off. There was no moist desquamation under the SkinSafe film in the inframammary field in any patient. Axillary moist desquamation, where no film, but rather physician's choice of topical cream was applied, remained at 35%. Areas of skin adjacent to the SkinSafe film showed desquamation in 9.7% of patients, 0.5-1 cm in maximal diameter, all of which had resolved at time of completion.

Conclusions: Prophylactic use of SkinSafe film strips applied to the inframammary fold substantially reduces or eliminates the risk of inframammary desquamation during breast radiation.
Impact of regional nodal irradiation for breast cancer patients with supraclavicular and/or internal mammary lymph node involvement: A multicenter, retrospective study (KROG 16-14)

Kyubo Kim¹, Yuri Jeong², Kyung Hwan Shin³, Jin Ho Kim³, Seung Do Ahn³, Su Ssan Kim³, Chang-Ok Suh⁴, Yong Bae Kim⁴, Doo Ho Choi⁵, Won Park⁵, Jihye Cha⁶, Mison Chun⁶, Dong Soo Lee⁸, Sun Young Lee⁹, Jin Hee Kim¹⁰ and Hae Jin Park¹¹. ¹Ewha Womans University College of Medicine, Seoul, Korea; ²Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; ³Seoul National University College of Medicine, Seoul, Korea; ⁴Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea; ⁵Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; ⁶Wonju Severance Christian Hospital, Wonju, Korea; ⁷Ajou University School of Medicine, Suwon, Korea; ⁸Uijeongbu St. Mary's Hospital, The Catholic University of Korea, Uijeongbu, Korea; ⁹Chonbuk National University Hospital, Jeonju, Korea; ¹⁰Keimyung University Dongsan Medical Center, Keimyung University School of Medicine, Daegu, Korea and ¹¹Hanyang University College of Medicine, Seoul, Korea.

Purpose: To evaluate the treatment outcomes of radiotherapy (RT) for breast cancer with ipsilateral supraclavicular (SCL) and/or internal mammary (IMN) lymph node involvement.

Methods: A total of 353 patients from 11 institutions were included. One hundred and thirty-six patients had SCL involvement, 148 had IMN involvement, and 69 had both. All patients received neoadjuvant systemic therapy followed by breast conserving surgery or mastectomy, and postoperative RT to whole breast/chest wall. As for regional lymph node irradiation, SCL RT was given to 344 patients, and IMN RT to 236 patients. The median RT dose was 50.4 Gy.

Results: The median follow-up duration was 61 months (range, 7-173). In-field progression was present in SCL (n=20) and/or IMN (n=7). The 5-year disease-free survival (DFS) and overall survival rates were 57.8% and 75.1%, respectively. On multivariate analysis, both SCL/IMN involvement, number of axillary lymph node ≥4, triple negative subtype, and mastectomy were significant adverse prognosticators for DFS (p = 0.022, 0.001, 0.001, and 0.004, respectively). Regarding the impact of regional nodal irradiation, SCL RT dose ≥54 Gy was not associated with DFS (5-yr rate, 52.9% vs. 50.9%, p = 0.696) in SCL-involved patients, and the receipt of IMN RT was not associated with DFS (5-yr rate, 56.1% vs. 78.1%, p = 0.099) in IMN-involved patients.

Conclusion: Neoadjuvant chemotherapy followed by surgery and postoperative RT achieved an acceptable in-field regional control rate in patients with SCL and/or IMN involvement. However, a higher RT dose to SCL or IMN RT was not associated with the improved DFS in these patients.
Comparison of accelerated partial breast irradiation (APBI) with whole breast irradiation (WBI) using 3D conformal external beam radiation therapy (3D CRT)

Budhi S Yadav¹, Sofia L¹, Suresh C Sharma², Rajinder Singh³ and Divya Dahiya¹. ¹PGIMER, Chandigarh, India; ²MIMS, Mullana, India and ³CMC, Chandigarh, India.

Purpose:
To compare accelerated partial breast irradiation with whole breast irradiation in post breast conservation surgery (BCS) women with breast cancer.

Material and methods:
Women >35 years of age with invasive or noninvasive breast cancer ≤4 cm treated by BCS were randomized to 3D CRT APBI (34 Gy in 10 fractions given twice daily) or WBI (40 Gy in 16 fractions given once daily ± boost irradiation). The primary outcome was ipsilateral breast tumour recurrence and important secondary outcomes were adverse cosmetic outcome (fair or poor on a HARRVARD/NSABP/RTOG breast cosmesis grading scale) and toxicity using the RTOG scores and LENT SOMA scale. Radiation toxicities and cosmesis was assessed directly by radiation oncologist during radiotherapy and in follow up. Patient and tumour characteristics, locoregional recurrence and distant metastases rates were compared using Fisher's exact tests. All statistical tests were two sided p values less than 0.05 were considered statistically significant.

Results:
Between June 2011 and December 2015, 133 women were randomized to 3D CRT APBI or WBI. Patient characteristics were balanced between two arms

. There was an increased rate of acute grade 2 dermatitis in WBI arm (p=0.33). Median follow up was 60 months (range 9-84 months). Grades 1 and 2 late radiation toxicities were higher in the WBI arm compared to the APBI arm; pigmentation, fibrosis and breast shrinkage were significantly more in the WBI arm. Grades 3 and 4 late toxicity was not seen in any of the treatment arms. Adverse cosmesis at last follow up was significantly higher in patients treated with WBI, 32% as compared to 6% with APBI (p=<0.001). Local recurrence with APBI was 3% as compared to 1.5% with WBI and distant metastasis rate was high in WBI arm as compared with APBI, 5.9% vs 3% respectively; both not statistically significant.

**Conclusion:**
In women with BCS, APBI was associated with better cosmetic outcome and late radiation toxicities compared to WBI. Local recurrence and distant metastasis was comparable in both the arms.
Incidence of radiation induced sarcoma attributable to radiotherapy in adults: A population-based study of the SEER cancer registry across 17 primary tumor sites

Anson E Snow¹, Lucas C Struycken³, Melissa Koc², John P Greco¹, Yue Zhu¹, Gino K In¹, Tania B Dorff⁴ and Julie E Lang¹. ¹USC Norris Comprehensive Cancer Center, Los Angeles, CA; ²Southern California Clinical and Translational Science Institute, Los Angeles, CA; ³University of Arizona Banner University Medical Center, Tucson, AZ and ⁴City of Hope, Duarte, CA.

Background: More than half of cancer patients will receive radiotherapy during the treatment of their cancer; however, a rare and fatal treatment complication is radiation induced sarcoma (RIS). Notably, a large percentage of RIS patients are breast cancer survivors. Previous studies have investigated the incidence of all secondary cancers due to radiotherapy but have not noted the incidence of RIS in a contemporary population-based cohort in the US. To evaluate the relative risk of RIS, we examined data from the Surveillance, Epidemiology, and End Results (SEER) database. We hypothesized that breast cancer would have a higher incidence of RIS compared to 17 other primary cancer sites.

Methods: This was a retrospective cohort study that examined SEER registries from 1973 and 2013. We included patients aged 18 years or older who were diagnosed with a primary cancer. We excluded patients with missing information on initial radiotherapy treatment or stage and those who died less than two years from the date of their primary cancer diagnosis. RIS was defined as those who developed a secondary sarcoma near the site of their original malignancy and after a 24-month latency period.

Results: Our study included 1,745,867 patients with an average age of 60 years and mean follow up time of 9.2 years. Breast cancer comprised the largest number with 693,701 patients of which 161 (0.02%) had a secondary sarcoma. Prostate cancer comprised the second largest group with 594,271 patients of which 75 (0.01%) had a secondary sarcoma. Of the 359 patients with secondary sarcomas, 242 (67.4%) had RIS. Breast cancer had the highest number of RIS patients at 126 (52.1%) compared to all combined non-breast cancer sites at 116. Interestingly, 172 (71.1%) RIS patients were females, which correlated with the attributable RIS cases from breast and uterine cancer. The relative risk of RIS in breast cancer versus 17 other primary cancer sites was 1.21 (CI: 1.01-1.45, p <0.03, adjusted for age at primary diagnosis, gender, and latency).

Conclusions: This study confirms the low incidence of RIS in breast cancer, which has been demonstrated to be around 0.03% - 0.2% in the literature. Our results suggest that breast cancer portends a somewhat higher risk for RIS compared to 17 primary solid malignancies. Although some of the risk is attributable to the high incidence rate of breast cancer, breast cancer patients had a higher relative risk of RIS than other solid tumors after adjusting for covariates. Female gender may be associated with an increased risk for RIS compared to males. Further investigations should be performed to confirm these epidemiological findings given that radiation fields, doses, intention to cure, margin status and systemic therapy are not recorded in SEER. Nonetheless, this study is hypothesis generating in that the majority of RIS cases in solid tumors are attributable to breast cancer in this large population-based series.
Five year outcomes of a prospective study of proton radiotherapy for breast cancer regional nodal irradiation

Julie A Bradley¹, Roi Dagan¹, Xiaoying Liang¹, Meng Wei Ho¹, Michael Rutenberg¹, Raymond Mailhot¹, Christopher Morris¹ and Nancy P Mendenhall¹. ¹University of Florida, Jacksonville, FL.

Purpose: Through improved nodal coverage and decreased dose to the heart and lung, proton therapy (PT) may improve the therapeutic ratio for treatment of breast cancer requiring regional nodal irradiation (RNI). The purpose of this study is to report 5 year disease control and toxicity.

Methods: From May 2012 to February 2014, 18 women (stage IIA-IIIB) prospectively enrolled on a pilot study. Median age was 52 years (range, 42-73), with equal division between breast-conserving therapy (BCT) and mastectomy and right and left-sided cancers. Median number of positive nodes among the 16 node-positive patients was 2 (range, 1-14). Five patients had ≥ 10 nodes positive on axillary dissection (N3a). Treatment targets (CTVs for breast/chest wall, supraclavicular, axillary, internal mammary nodes (IMNs)) and organs at risk were delineated on CT scans. Double scatter PT alone was used for 10 patients (9 post-mastectomy, 1 after BCT) and combined proton-photon in 8 (all BCT). Toxicity was prospectively recorded using CTCAE v4.0.

Results: Median follow-up was 4 years (range, 0.3 – 6). 5 year overall survival was 82% and locoregional control was 100%. 5 year distant metastases-free survival was 82%. No grade 4+ toxicity developed. Four patients developed grade 3 cellulitis, which was the only grade 3 toxicity. One patient had a reconstructive failure associated with a post-surgical cellulitis. A right-sided patient was diagnosed with CHF within 2 months of completion of PT, following diagnosis of a pulmonary embolus 1 month prior. She had an elevated BNP (1101) prior to PT following adriamycin-based chemotherapy. Mean heart dose was 0 Gy and cardiac V5 0%. Atrial fibrillation developed in two patients. One patient developed grade 2 pneumonitis (she received concurrent chemotherapy). One patient, with a history of rib fractures prior to PT, developed an ipsilateral rib fracture 7 months after PT.

Conclusion: In a population of women with locally advanced breast cancer, PT for RNI has proven feasible after either mastectomy (with or without reconstruction) or BCT with excellent locoregional control. PT allows for highly conformal radiation delivery without compromise of target coverage or excess exposure of normal tissue. Documentation of the ultimate benefits of PT in this population, freedom from radiation induced cardiac disease and breast cancer recurrence will require prospective study of a larger numbers of patients.
Intraoperative radiotherapy (IORT) after neoadjuvant chemotherapy in patients with breast cancer—Experience in the Cancer Institute of Lima-Peru

Jose M Cotrina¹, Jose A Galarreta¹, Miguel A Pinillos¹ and Sheila Vilchez¹. ¹National Cancer Institute, Lima, Peru.

Background
Intraoperative radiotherapy (IORT) is a treatment technique that allows the surgical bed to be irradiated in the same surgical act after breast-conserving surgery, in some cases as a single treatment and in others as a boost complemented with external radiotherapy. There are studies that have shown their non-inferiority with respect to conventional external radiotherapy, taking advantage of administration time, costs and side effects.

Methods
In this study, the IORT (INTRABEAM) was used as treatment in patients who received neoadjuvant treatment with chemotherapy who had a good response and met the criteria to be included (no tumor or tumors less than 3 cm, unifocal tumors, no skin involvement after treatment).

Out of a total of 255 cases of IORT performed in recent years, 42 were studied, those who received neoadjuvant chemotherapy from April 2014 to April 2018 and who completed the treatment.

Results
The average age was 47.9 years (29-72), 59.5% were between 40-49 years old and 11.4% were under 40 years old. 61.9% were stage II and 38.1% stage III. The diameter of the most used applicator was between 3-3.5 cm (56.8%) and the average irradiation time was 20 mins (12-46 mins). All received external RT. 67.6% received on average 25 sessions and 32.4% received 15 sessions. There were 64.2% luminal (luminal A 7.1%, luminal B 38.1%, luminal B HER2 (+) 19%), 7.1% with ER/PR(-) HER2(+) and 28.6% ER/PR(-) HER2(-). 38% patients had complete pathological response in the primary tumor. Of the 42 patients treated, 37 had a follow-up of more than 6 months. 3 (7.1%) had recurrence, 2 local and 1 local and distant (EC IIIC). Disease-free survival at 12, 24 and 36 months was 97.2%, 90.5% and 90.5% and the overall survival was 100%, 100% and 92.3% respectively.

Conclusion
The IORT (INTRABEAM) used as a boost in patients with breast cancer and neoadjuvant treatment who complete complementary external RT, is a safe procedure, with low recurrence rate, it is easy to perform with a good tolerance, shorter time of treatment and with fewer side effects.
Comparison of three different topical agents on prevention of acute radiodermatitis during breast cancer radiotherapy

Duygu Sezen, Yasemin Bolukbasi, Cansu Corak Cebi and Ugur Selek.

1 Koc University, School of Medicine, Istanbul, Turkey and 2 American Hospital, Istanbul, Turkey.

Aim: To compare the effectiveness for radiodermatitis prophylaxis of Fusidic acid and Betamethasone valerate containing cream, pure vaselin and emollient dermatocosmetic cream during radiotherapy for breast cancer.

Method: We prescribed one of the 3 different creams per patient respectively at the start date of breast cancer radiotherapy (conventional radiotherapy: CRT, 50 Gy in 2 Gy/fraction plus a 10 Gy boost for a total of 60 Gy; or hypofractionated radiotherapy: HRT, 40 Gy in 2.67 Gy/fraction plus a 10 Gy Boost for a total of 50 Gy) at our clinic and instructed them to use the cream daily after each fraction throughout the whole treatment. Weekly photographs of the thorax, including the treated breast anteriorly and laterally, were taken with the onset of treatment, where a gray card setting for color balance standardization was performed. The weekly skin changes were recorded prospectively and assessed retrospectively according to the RTOG radiodermatitis side effect scale. A total of 64 cases have been enrolled in the study till now and 54 out of 58 cases who completed their radiotherapy were evaluated for the current analysis (photographs flawed in three, one refused her photographs to be included in the study). The photographs were processed for color matching with the gray card set using the Adobe Reader Photoshop CC software via the red color histogram and the pre- & post-radiotherapy skin redness were objectively compared via the histogram. The data were analyzed using SPSS, version 23.

Results: The treatment was conventional in 25 patients and hypofractionated in 29 patients. Grade 2 radiodermatitis was seen in 37% of the cases at the end of treatment. The color scale final grade 2 radiodermatitis rate was 29.6% (16 cases), consistent with the clinical findings. The cream used was emollient dermatocosmetic in 17 (31.5%, CRT 10, HRT 7), fusidic acid and betamethasone valerate in 19 (35.2%, CRT 13, HRT 6), and pure vaseline in 18 (33.3%, CRT 6, HRT 12) cases. There were 4 grade 1 RD in first week, 15 grade 1 RD in second week, 29 grade 1 and 1 grade 2 RD in the third week. The grade 2 RD rate increased to 16.7% (9) in the fourth week. As lower red density values in the red scale representing increased erythema, the pre-radiotherapy breast median value of 230 (range: 166-256) decreased to a median value of 209.5 (range: 114-252) at the end of radiotherapy with a median change of 14%, not significantly different with creams (p=0.06) or with fractionation (p>0.05). Conclusion: Grade 2 acute radiodermatitis was less commonly encountered with prophylactic creams in our cohort while no significant difference could be defined between creams and fractionation used. Digital follow up of the protocol patients is currently continuing to be documented for future reporting.
The use of new delineation tool “MIRADA”, step-by-step development and first results of its use in early and locally advanced breast cancer patients

HaoPing Xu\textsuperscript{2,1}, Alexandre Arsene Henry\textsuperscript{1}, Magalie Robillard\textsuperscript{1}, Malika Amessis\textsuperscript{1} and Youlia M Kirova\textsuperscript{1}. \textsuperscript{1}Institut Curie, Paris, France and \textsuperscript{2}Rujin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Objectives: To describe the practical procedure of implementation and optimization of delineation using “Mirada” software, as well as evaluation of the automatic segmentation for the daily practice of lymph nodes (LN) and OARs (organs at risk) in early as well as locally advanced stage breast cancer patients.

Methods: Forty patients' CT scans in treatment position were selected and re-contoured according to the ESTRO guidelines. The atlas of dataset was then created for automatic delineation. Thirty patients with breast/chest wall and lymph nodes regions irradiated were recruited for evaluation. With the same treatment position, the CT scan images were acquired and then contoured by the MIRADA system automatically as well as by the radiation oncologist manually (as the reference). The Conformity Index (CI) was used to evaluate the concordance between both of them.

Results: The mean time for manual contour was 24.1±5.1 mins and 26.4±2.8 mins for the LN and the OARs resp. All the volumes of interest were contoured using the software (including corrections) in 30 minutes, which reduced the time of delineation of target volumes and OAR by about 40%. Of the 30 cases evaluated, the mean CI of 5 principal OARs showed ≥ 0.8. While the automatic contour of LN was less satisfactory with mean CI of 0.43±0.1 (0.23-0.52).

Conclusions: For the breast cancer patients, the studied software permitted to save time for delineation with acceptable OAR contours. The improvement of LN regions contour is needed. More cases and further evaluation are needed for the system to realize its routine use.
Development of peptide-based targeted α-therapy for triple negative breast cancer

Jessie R Nedrow, Angel Cortez, Anders Josefsson and George Sgouros. 1Johns Hopkins University, Baltimore, MD.

Triple-negative breast cancer (TNBC) is associated with a poorer prognosis, including a higher potential to metastasize and a decrease in the 5-year survival rate as compared to other breast cancer subtypes (77% vs. 93%). The poor prognosis is partially due to the lack of targeted treatments for TNBC, highlighting the need to develop targeted therapies for TNBC. Alpha-emitting radionuclides, such as Actinium-225, provide high linear energy transfer (LET) radiation. Clinical and pre-clinical studies have shown that targeted alpha-therapy is a highly potent treatment for metastatic cancer. Peptides and peptidomimetics are minimally immunogenic and have rapid tissue and tumor penetration, and rapid clearance from non-target tissues, providing an attractive platform for targeted therapeutic agent. The RGD peptide has been shown to have a high affinity for \( \alpha_v \beta_3 \), which has been implicated in TNBC. The purpose of these studies is to investigate the potential of modified RGD peptide scaffolds to deliver \( ^{225}\text{Ac} \) to triple negative breast cancer cells for targeted alpha therapy.

Methods

DOTA-cyclo-RGD(fK) and DOTA-cyclo-RGD(fK) dimer were labeled with Indium-111, a SPECT imaging surrogate for \(^{225}\text{Ac} \), and Actinium-225. The resulting labeled agents were evaluated in vitro, including binding affinity assays \((^{111}\text{In})\) and colony formation assays \((^{225}\text{Ac})\) that are underway using the MDA-MB-231 cell line. Biodistribution experiments were performed in athymic nude mice bearing MDA-MB-231 tumors to compare the distribution and pharmacokinetics of the \(^{111}\text{In}\)-labeled RGD peptide scaffolds in vivo. Alpha camera imaging evaluated the microscale distribution of \(^{225}\text{Ac}\)-DOTA-cyclo-RGD(fK) in non-tumor bearing mice.

Results

The saturation binding assay of \(^{111}\text{In}\)-labeled DOTA-cyclo-RGD(fK) and DOTA-cyclo-RGD(fK) dimer demonstrated selective binding and nanomolar affinity for \( \alpha_v \beta_3 \). Selective targeting of \( \alpha_v \beta_3 \) was further demonstrated in vivo for both \(^{111}\text{In}\)-labeled RGD agents. The \(^{111}\text{In}\)-labeled DOTA-cyclo-RGD(fK) dimer demonstrated significantly higher tumor uptake at 30 minutes compared to the dimer (5.3 ± 2.9 vs. 3.0 ± 1.4 %ID/g). The \(^{111}\text{In}\)-DOTA-cyclo-RGD(fK) dimer was better retained in the tumor over 6 hours with significantly higher uptake at the 6-hour time point (1.2 ± 0.4 vs. 2.8 ± 1.1 %ID/g). Furthermore, the dimer had significantly higher uptake in the kidney and liver over a 6-hour window as compared to \(^{111}\text{In}\)-DOTA-cyclo-RGD(fK). However, both \(^{111}\text{In}\)-labeled RGD agents demonstrated rapid clearance from normal organs. Alpha camera images of the \(^{225}\text{Ac}\)-labeled dimer supported the rapid clearance from the normal tissues, with the majority of the agents being cleared within the first 90 minutes.

Conclusion

Modified RGD peptides were successfully labeled with Indium-111 and Actinium-225. The resulting agents were shown to successfully target \( \alpha_v \beta_3 \) selectively both in vitro and in vivo. These studies provide encouraging data to support the development and optimization of the RGD platform for \( \alpha_v \beta_3 \)-targeted alpha therapy to treat triple negative breast cancer. Future works will investigate the therapeutic efficacy, macro- and microscale dosimetry, and toxicity of the developed \(^{225}\text{Ac}\)-labeled \( \alpha_v \beta_3 \)-targeted agents as well as explore the optimization of the RGD scaffold for improved pharmacokinetics with \(^{225}\text{Ac}\).
Targeted intraoperative radiotherapy (TARGIT IORT) during breast conserving surgery for early stage breast cancer in patients with breast augmentation with implants

Hans-Christian Kolberg1, Valery Uhl2, Samuele Massarut3, Dennis Holmes4, Cornelia Liedtke5, Erica Whineray Kelly6, György Lövey7 and Jayant S Vaidya8. 1Marienhospital Bottrop, Bottrop, Germany; 2Summit Medical Center, Emeryville, CA; 3Centro di Riferimento Oncologico di Aviano, Aviano, Italy; 4John Wayne Cancer Institute, Santa Monica, CA; 5Charité - Universitätsmedizin Berlin, Berlin, Germany; 6Auckland Breast Centre, Auckland, New Zealand; 7BORAD, Bottrop, Germany and 8University College London, London, United Kingdom.

**Background:** Targeted intraoperative radiotherapy (TARGIT) has become a standard option during breast conserving surgery for selected cases of early breast cancer and over 20,000 patients have been treated in over 300 centers around the world. Although a growing number of patients are presenting with implant breast augmentation, no data has been published regarding the safety of TARGIT with implants in situ. TARGIT IORT as a replacement for whole breast irradiation is an important issue in this context because of the high rates of capsular fibrosis following EBRT in such patients.

**Methods:** We are reporting a case series of 12 patients who received TARGIT during breast conserving surgery for early breast cancer, had undergone breast augmentation with implants before and wanted their implants to stay in situ. Patients were informed that no published data existed and decided on this approach on an individual basis. 3 patients received additional EBRT after TARGIT IORT because of the presence of EIC or LVI. TARGIT IORT was performed using Intrabeam - 50 kV – X-rays delivering 20 Gy prescribed at the surface of the tumor bed during the initial lumpectomy procedure.

**Results:** Patient characteristics are given in table 1. Follow-up varied from 78 months to 3 months. 11 patients presented with invasive breast cancer, 1 patient with DCIS. There were no procedure related complications and none of the patients have needed their implant removed. 1/12 patients (ID 7) was diagnosed with a local recurrence in a distant quadrant after 36 months of follow-up. In 11/12 patients no breast-cancer-related events occurred.

**Conclusion:** This series of patients with TARGIT during breast conserving surgery for early breast cancer after breast augmentation with implants demonstrates that TARGIT IORT is a safe and effective treatment option for patients who desire to keep their implants in situ.
augmentation with implants in situ revealed no safety concerns. Our case series gives some confidence in discussing this option with suitable patients. To expand this series, we are gathering details about other cases from the whole TARGIT group worldwide.
Utilization and survival benefit of radiation therapy among hormone receptor positive breast cancer patients with recurrence score from Oncotype DX testing

Lu Zhang¹, Mei-Chin Hsieh¹, Valentina I Petkov², Xiao-Cheng Wu¹ and Qingzhao Yu¹. ¹Louisiana State University Health Sciences Center, New Orleans, LA and ²National Cancer Institute, Rockville, MD.

Background: Radiation therapy (RT) improves survival of breast cancer (BC) patients receiving the lumpectomy. Oncotype DX, a 21-gene Recurrence Score (RS) assay, has been validated to predict the risk of recurrence and chemotherapy benefit for hormone receptor positive (HR+) BC without metastatic lymph nodes (PN0). With increasing use of Oncotype DX, it is unclear if the utilization and survival benefit of RT vary by RS in clinical practice. This study aimed to 1) examine if the RS from Oncotype DX testing influences RT utilization among HR+ BC patients with PN0 who received lumpectomy; and 2) investigate if RT is associated with better cause-specific survival (CSS) and overall survival (OS) among patients stratified by the low, intermediate, and high RS.

Methods: Data from Genomic Health Inc., the sole Oncotype DX testing provider in the U.S., was linked with routinely collected data from 17 SEER registries. Women who were diagnosed with PN0 and HR+ BC in 2004-2015, received the lumpectomy, and had RS from Oncotype DX testing were included. Patients who had multiple tumors, received RT before or within surgery, or had less than 2 months follow-up were excluded. Patients diagnosed in 2004-2014 and followed through the end of 2015 were included in the survival analysis. RS was categorized into low (<18), intermediate (18-30), and high (>30). RT was categorized into yes, no or unknown. Multivariable logistic regression was applied to examine the association between RS and RT utilization. To compare survival differences, patients receiving RT and patients having no or unknown RT were matched on propensity score, which was calculated based on diagnosis year, age, race, marital status, tumor size, grade, number of lymph nodes examined, chemotherapy, and participating state. Stratified Cox proportional hazards models were used to compare CSS and OS between two matched groups. Proportional hazard assumption was evaluated.

Results: Out of 48,615 patients, 56.8% had low, 36.1% had intermediate, and 7.1% had high RS; 84.5% received RT (86.6%, 82.8%, and 76.4% in low, intermediate, and high RS patients, respectively; P < 0.0001). After adjusting for covariates, patients with intermediate (odds ratio [OR] 0.75; 95% CI 0.71-0.79; P < 0.0001) and high RS (OR 0.53; 95% CI 0.47-0.59; P < 0.0001) were less likely to receive RT than patients with low RS. Among patients with low or intermediate RS, having no or unknown RT was associated with worse CSS (low RS: hazard ratio [HR] 6.00, 95% CI 1.77-20.37, P = 0.004; intermediate RS: HR 2.12, 95% CI 1.19-3.77, P = 0.01) and OS (low RS: HR 2.29, 95% CI 1.56-3.35, P < 0.0001; intermediate RS: HR 2.22, 95% CI: 1.54-3.21, P < 0.0001). RT utilization was not significantly associated with CSS or OS among patients with high RS.

Conclusions: Among HR+, PN0 BC patients receiving the lumpectomy, lower RS was associated with higher RT utilization. RT was associated with better CSS and OS among patients with low or intermediate RS. Among patients with high RS, no association between RT and survival was observed.
Tumor-secreted predictive biomarkers of response to radiotherapy in breast cancer

James Meehan\textsuperscript{1}, Mark Gray\textsuperscript{1}, Arran K Turnbull\textsuperscript{1}, Carlos Martinez-Perez\textsuperscript{1}, Maria Bonello\textsuperscript{1}, Carol Ward\textsuperscript{1}, Simon P Langdon\textsuperscript{1}, Steve McLaughlin\textsuperscript{2}, Marjory MacLennan\textsuperscript{3}, J Michael Dixon\textsuperscript{3}, Jimi Wills\textsuperscript{1}, Niall Quinn\textsuperscript{1}, Andrew J Finich\textsuperscript{1}, Alex von Kriegsheim\textsuperscript{1}, David Cameron\textsuperscript{1}, Ian H Kunkler\textsuperscript{1}, Alan Murray\textsuperscript{4} and David Argyle\textsuperscript{5}. \textsuperscript{1}Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom; \textsuperscript{2}Institute of Sensors, Signals and Systems, School of Engineering and Physical Sciences, Heriot-Watt University, Edinburgh, United Kingdom; \textsuperscript{3}Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom; \textsuperscript{4}School of Engineering, Faraday Building, King’s Buildings, University of Edinburgh, Edinburgh, United Kingdom and \textsuperscript{5}The Royal (Dick) School of Veterinary Studies and Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom.

Background: In breast cancer (BC), radiotherapy (RT) is used adjuvantly to prevent recurrence and also in the palliative setting. Clinical signs of RT response are often not apparent for several weeks post-treatment and we currently lack tools to predict or monitor tumor response to RT early during treatment. The aim was to identify tumor-secreted biomarkers whose release reflects response to RT, which could be monitored during treatment in the blood or intratumorally by an implantable biosensor, currently under development within the Implantable Microsystems for Personalised Anti-Cancer Therapy (IMPACT) program.

Methods: A series of experiments assessed the effect of different radiation doses (2-10Gy) on 3 human BC cell lines – MDA-MB-231 (ER-), MCF-7 (ER+) and HBL-100 (ER-) –, 1 canine breast cancer and 2 sheep lung cancer lines. Culture media was collected from each dose experiment at a range of post-radiation time-points (1-24 hours). Proteins were isolated from collected media for secretome mass spectrometry (MS) analysis. A subset of treatment/time conditions were repeated in the same BC cell lines and radioresistant (RR) derivatives from which RNA was extracted and analysed using Lexogen QuantSeq for whole-genome transcriptomics. In-lab candidate biomarker validation was carried out using immunohistochemistry (IHC), immunofluorescence (IF) and western blotting (WB) using validated antibodies. Levels of candidate biomarkers were also assessed in normal and untreated BC tissues using IHC. ELISA-based methods are currently under investigation for detection of the lead candidate biomarkers in the blood of large animal cancer models treated with RT.

Results: Biomarker discovery using the MS data revealed 4 promising candidates: EIF3G, SEC24C, YBX3 and TK1. These are released from BC and animal cancer cells sensitive to radiation in a dose-dependent manner 24 hours after treatment. Analysis of the transcriptomic data showed an 8-fold higher expression of the genes encoding the 4 candidates in the radio-sensitive parental cell lines compared to the RR cell lines. IF and WB confirmed lower intracellular expression of the 4 proteins in RR cells compared to the parental lines. WB of collected culture media confirmed release of each of the 4 candidates 24 hours after a 2Gy dose of radiation in only the parental lines. GAPDH was not found in these media samples, demonstrating that protein release was not due to cell lysis.

Conclusions:
\begin{itemize}
  \item We have identified 4 promising biomarkers which are released from cancer cells sensitive to RT and not released from RR derivatives.
  \item All 4 candidates are released 24 hours after a 2Gy radiation dose, which fits with the current clinical dosing schedule where radiation is administered at 24 hour intervals. Ongoing work will elucidate if these biomarkers can be reliably detected in blood or intratumorally using implantable biosensors.
  \item There are currently no validated predictive tools to monitor RT response during treatment. If successfully validated, these biomarkers could have a clinical role in personalising RT dosing schedules and durations for solid tumors in the neoadjuvant and palliative setting, thus optimising treatment and preventing the administration of ineffective RT and its associated side effects.
\end{itemize}
Dosimetric impact of patient rotation during prone breast radiotherapy

Karen Cheng¹, Scott Hoopingarner², Cari Wright², Megan Daly², Ruben Fragoso² and Xiao Zhao². ¹Boston University School of Medicine, Boston, MA and ²UC Davis Department of Radiation Oncology, Sacramento, CA.

Purpose
Prone positioning has been used as a viable alternative to conventional supine position for patients receiving breast radiation therapy. However, little research has been done exploring the axial rotation of patients toward the treated breast when “sinking” into the opening of the breast board and its potentially negative effects on dosimetric outcomes, which may include increased heart and lung dose. The physician may need to move the posterior border away from the chest wall to reduce heart and lung dose.

Methodology
49 consecutive female patients with left sided early stage breast cancer treated at University of California Davis Medical Center were assessed from 2015 to 2018 (age range: 42-84 years, median age: 62 years). All patients underwent prone whole breast therapy with conventional external beam radiation therapy (EBRT) at doses of 50 Gy (n = 12) or hypofractionated at 42.56 Gy (n = 37). Treatment plans and dose volumes were retrospectively analyzed for each patient. Standard tangents were designed for each patient using clinical landmarks of the midaxillary line and midsternal line, which were then compared to the delivered tangent beams. The angle created between a vertical line centered on center sternum and a line drawn from center sternum to center spinal cord served to define degree of axial rotation. Breast depth was defined by the longest horizontal length from outer rib to edge of breast on sagittal view. Patients were divided into subgroups by degree of rotation and absolute breast depth. A two tailed paired Student’s t-test was used for analysis.

Results
Overall mean heart and lung dose were 82.2 cGy and 50.43 cGy for the entire cohort, respectively. For standard tangents, patients with degree of rotation < 5 degrees in the prone position (n = 23) had significant lung sparing as compared to patients with degree of rotation > 5 cm (n = 26) (mean lung dose: 61.8 cGy vs 129.6 cGy, p = 0.00329). This was also seen for cardiac sparing (mean heart dose: 105.9 cGy vs 183.9 cGy, p = 0.000235). Even with reduction of posterior border for treatment delivery, there remained a significant increase in mean heart and lung dose with increased rotation (p = 0.038, p = 0.046). Although not statistically significant, for patients with > 5 degrees of rotation there was a trend toward increased reduction of the posterior border of the tangent (13 mm vs. 7.5 mm, p = 0.13). A significant predictor of increased rotation was breast depth > 10 cm (p = 0.01). Patients with absolute breast depth > 10 cm (n = 23) in the prone position had significant lung sparing as compared to patients with absolute breast depth < 10 cm (n = 26) (mean lung dose: 58.6 cGy vs 40.8 cGy, p = 0.042).

Conclusion
To our knowledge, this is the first dosimetric comparison of prone breast therapy exploring the degree of patient roll into the prone-breast setup cavity. This study demonstrates a significant increase in mean lung and heart dose when patient rotation is greater than 5 degrees. Given this, the posterior border may have to be reduced to prevent a higher than intended dose to the heart and lung. Proper attention during simulation is important to allow for optimal dose distribution and special attention should be paid to women with smaller breast size.
Application of supine MRI-based 3D printing breast surgical guide for precision breast-conserving surgery

Beomseok Ko¹, Namkug Kim¹, Joonbeom Seo¹, Hakhee Kim¹, Gyungyub Gong¹, Sungbae Kim¹, Byungho Son¹ and Sei Hyun Ahn¹. 'Asan Medical Center, University of Ulsan, Seoul, Republic of Korea.

Background
If the size of the tumor is large, neoadjuvant systemic therapy (NST) is performed to reduce the size of the tumor and to conserve the breast. It is known that magnetic resonance imaging is more accurate than mammography (MMG) or ultrasonography (USG) in determining the area of residual cancer in breast-conserving surgery (BSG) after NST. However, there are some problems when performing BCS using MRI. Because the posture of MRI test is different from the posture at surgery, it is difficult to accurately mark the area of the tumor observed in MRI. Neoadjuvant systemic therapy reduces tumor size and often makes it difficult to detect the original tumor area on preoperative MRI. Even if the tumor is not visible in the image, the cancer cells may remain, so it is important to accurately indicate the extent of the initial tumor and remove it. Until now, however, there has been no way to accurately mark past breast tumors in the breast. We have developed a breast surgical guide (BSG) that can mark a range of tumor directly on the breast using three-dimensional printing technology based on supine MRI. This study analyzed the results of patients who underwent BCS using a 3D printing breast surgical guide (3D-BSG) based on supine MRI.

Methods
This trial was designed as a prospective single-institution cohort study. Our study protocol was approved by the Institutional Review Board of Asan Medical Center, Seoul, Korea (IRB No. 2016-1237). Patients who were expected to undergo BCS after NST were enrolled in this study and supine MRI was performed before and after NST. From MRI images, morphological shapes of breasts and tumors were modeled. The prepared digital model was saved in stereolithography file format and then exported to a 3D printer. 3D-BSG is designed to be able to mark the skin and attach the dye injecting column to mark the around the tumor. The breast tissue was removed with blue dye on the basis of the border. To obtain tumor free margin, intraoperative frozen sections were identified in several cavities and re-excision was performed if tumor positive.

Results
Between January 2016 and May 2017, 50 patients were enrolled in the study. BCS was applied to 40 patients, except for those who were rejected or mastectomy. Complete remission was observed in 15 patients after NST. Four patients had tumor positive on resection margins on frozen biopsy during operation, two with IDC and two with DCIS. Re-excision was performed in these patients and tumor negative margin was confirmed in all patients in the final pathology results. The median size of the long axis of the tumor was 1.7 cm (range, 0.5 to 4.5 cm) and the median size of the long axis of the removed breast tissue was 5.1 cm (range, 2.3 to 8.1 cm). The distance between tumor and resection margin was 1.2 cm (range, 0.1 to 4.8 cm).

Conclusions
In BCS, the application of the supine MRI based 3D-BSG showed low rates of positive margins. Unlike conventional localization techniques, application of 3D-BSG does not cause pain to the patient, has no radiation exposure, and has no time required for the localization procedure, so it will be helpful for patients in BCS in the future.
Breast conserving therapy after neoadjuvant systemic therapy in patients with T3 breast cancer is feasible

Marieke EM van der Noordaa¹, Marie-Jeanne MTFD Vrancken Peeters¹, Ileana Ioan², Claudette E Loo¹, Japke van Urk¹, Erik van Werkhoven¹, Rosie Voorthuis¹, Terry Wiersma¹, Emilie Groen¹, Emiel Th Rutgers¹ and Frederieke H van Duijnhoven¹. ¹Antoni van Leeuwenhoek Hospital / Netherlands Cancer Institute, Amsterdam, Netherlands and ²Policlinico San Donato, Milano, Italy.

Background
An important advantage of neoadjuvant systemic therapy (NST) in breast cancer patients is down-sizing of the primary tumor. However, many patients with T3 tumors are treated with mastectomy regardless of response to NST. In this study, we evaluated predictive characteristics for positive margins and local control in T3 breast cancer patients who underwent breast-conserving therapy (BCT) after NST.

Methods
This single institution study included all clinical T3 breast cancer patients (determined by contrast-enhanced magnetic resonance imaging [MRI]) who underwent breast conserving surgery (BCS) after NST between 2000-2015. Clinical T3 was defined as a breast tumor >50mm on MRI pre-NST. Patient, tumor and treatment characteristics were recorded, as well as response on MRI and final pathology. The local recurrence probability was estimated with the Kaplan-Meier method. Predictive characteristics for positive margins in patients undergoing BCS were analyzed using Fishers exact test.

Results
In total, 115 T3 patients were identified. Patient, tumor and MRI findings are presenting in the table. Median tumor size was 60 mm on MRI pre-NST (range 51-120 mm) and 4 mm after NST (range 0-58 mm). Overall pathologic complete response was 19%: 5% in HR+/HER2- patients, 32% in HR-/HER2+ patients and 40% in TN patients. After initial BCS, 73 patients had negative margins (63.5%), 18 focally positive margins (15.7%) and 24 more than focally positive margins (20.9%). Patients with HR+/HER2- tumors (52%) were more likely to have positive margins than patients with HR-/HER2+ and TN tumors (21% and 19%, p=0.002). In addition, positive margins rate was higher in patients with lobular carcinoma compared to patients with ductal carcinoma (57 vs 32%, p=0.031). Presence of non-mass enhancement on pre-NST MRI was predictive for positive margins (52% in patients with and 25% in patients without non-mass enhancement, p=0.003). Of patient with positive margins, 15 underwent radiotherapy with boost, 6 underwent re-excision and 21 underwent mastectomy. Finally, 94/115 patients were treated with BCT (82%). Of these patients, two had a local recurrence after a median follow-up of 6.5 years (6-year local recurrence probability 2.6% (95%-CI 0-7%).

Conclusion
In this series, BCT after NST was successful in 82% of patients with T3 breast cancer and local control in this group was excellent. The positive margin rate after BCS was higher in patients with HR+ tumors, lobular carcinoma and tumors with non-mass enhancement on MRI pre-NST. BCT should always be considered in T3 cancers after NST.

Risk factors for reoperation following breast-conserving surgery integrated into pre- and postoperative models with high accuracy

Julia Ellrant¹, Eyvind Plassgård², Pär-Ola Bendahl² and Lisa Rydén². ¹Clinical Sciences Malmö, Surgery, Lund University, Malmö, Sweden and ²Clinical Sciences Lund, Surgery, Lund University, Lund, Sweden.

Purpose:
Breast-conserving surgery (BCS) is today applied in 60-70% of patients with invasive and in situ cancer and tumor size of 3 cm or less. However, a significant fraction of patients (10-40%) who undergo BCS require a reoperation due to incomplete excision of the tumor despite the evolvement of oncoplastic surgical techniques. We aimed to define risk factors for non-radical BCS due to positive margins in patients with in situ and invasive breast cancer operated with BCS. A specific focus was to identify preoperatively available characteristics which could be informative for the surgeon and patients when planning the primary choice of breast surgery.

Methods:
Patients with final diagnosis of in situ or invasive cancer who underwent BCS 2015-2016 at Skåne University Hospital in Malmö were included in the study. Patients undergoing neoadjuvant therapy were excluded. Data was extracted from mammography/ultrasound files, type of surgery from clinical files and pre-and postoperative pathological diagnosis and radicality from pathological files according to a prespecified protocol. The definition of radicality was according to international consensus (ie no tumor on ink for invasive cancer and 2 mm for in situ cancer). Uni- and multivariable logistic regression analysis were executed separately for pre- and postoperatively available parameters in the SPSS software to calculate odds ratios (OR) for predictors of non-radicality. Separate models for pre- and postoperative characteristics were defined based on data derived in 2015, 2016 was used as a validation set. Accuracy of the models were presented as AUC-values. P-values of ≤0.05 were considered significant.

Results:
202 patients diagnosed in 2015 were included of which 43 (21.3%) patients were considered non-radically operated, whereas 231 patients diagnosed in 2016 were eligible and had a reoperation rate of 14.3%. Multivariable analysis included determinants from the univariate analysis and clinically relevant variables with the following results for the preoperative model: mammographic size per mm: OR 1.06 (95% CI: 1.01-1.11), p=0.014, invasive lobular cancer on core needle biopsy vs not: OR 7.3 (95% CI: 1.8-29.4), P=0.005, DCIS diagnosis on core needle biopsy vs not OR 3.60 (95% CI: 1.00-13.02), p=0.051, benign core needle biopsy vs not OR 6.3 (95% CI: 0.9-46.7), p=0.070, oncoplastic surgery and presence of calcifications had p-values > 0.1. In the postoperative model pure DCIS in the specimen and total extent were significant predictive factors in the multivariate analysis. The preoperative model predicting non-radicality had an AUC of 0.81 and the postoperative model had an AUC of 0.86 in the test set (year 2015), the AUC in the validation set (year 2016) was 0.80 for the preoperative model and 0.81 for the postoperative model.

Conclusion:
Important preoperative prediction factors for non-radicality following BCS derived from core needle biopsies and mammograms have shown promising results and may be helpful when planning the primary choice of breast surgery. An extended study with larger cohort size is desirable.
18F-FDG micro-PET/CT for intraoperative margin assessment in breast conserving surgery using: A proof-of-concept study

Radoslaw Marcinkowski¹, Vincent Keereman¹, Roel Van Holen¹, Stefaan Vandenberghè², Mieke Van Bockstal³, Jo Van Dorpe³, Boudewijn Brans³, Menekse Goker³, Herman Depypere³ and Rudy Van den Broecke³. ¹MOLECUBES NV, Ghent, Belgium; ²MEDISIP, Ghent University, Ghent, Belgium and ³Ghent University Hospital, Ghent, Belgium.

Positive surgical margins represent a high risk for adverse clinical outcome in breast conserving surgery (BCS). Therefore, the goal of BCS is to avoid positive margins and hence avoid reoperation. Unfortunately, most studies currently assess the rate of positive resection margins at 20%. This is in part due to the lack of a time- and cost-effective method for intraoperative margin assessment, which would enable the prediction of positive margins during the initial surgery. We propose to address this problem by performing intraoperative high-resolution ¹⁸F-fluoro-deoxyglucose (FDG) positron emission tomography (PET) with X-ray computed tomography (CT). This method relies on the high sensitivity of FDG-PET for detecting metabolically active tumor tissue, and the delineation of the anatomical margins of the specimen using CT. In this proof-of-concept study we assess the feasibility of this technique.

Twenty patients with breast cancer that were eligible to undergo BCS were enrolled in the study after providing informed consent. The study was approved by the Ethics Committee of Ghent University Hospital. Prior to surgery each patient was administered 4 MBq/kg of FDG. Surgery was performed 2-4 hours after tracer administration. Following surgical excision the breast specimen was oriented with sutures and micro-PET/CT images were obtained using the MOLECUBES β-CUBE (PET) and X-CUBE (CT). The scan time was 10 minutes on PET and 3 minutes on CT. The specimen was then sent for histopathological assessment. Micro-PET/CT images were analyzed using an automated algorithm. Briefly, this algorithm defined the contour of the tumor as the region with high FDG uptake and the contour of the specimen based on the CT image. The margin status of a specimen was positive if the distance between the contour of the tumor and specimen was 0 mm. Images were also analyzed postoperatively by two surgeons blinded to the histopathological and algorithm analysis results. The sensitivity and specificity of the proposed method were then calculated by comparing to the histopathological results, which is the gold standard for margin status assessment.

In all samples a region with high FDG uptake was visualized, which corresponded to the tumor on histopathological. In one specific case a small satellite lesion with high FDG uptake, 3 mm in diameter, was detected on the micro-PET images at a distance from the main tumor. Histopathological confirmed that this previously undetected lesion was a second invasive carcinoma. For margin status, a sensitivity of 75% and specificity of 75% were obtained using automated algorithm analysis. Sensitivity and specificity obtained based on surgeons' analysis was 62.5% and 75% for surgeon A and 87.5% and 91.7% for surgeon B respectively. Taking into account the intra-operative micro-PET results could theoretically have reduced the reoperation rate by 75%.

This proof-of-concept study demonstrates that high-resolution intraoperative FDG-PET/CT is a promising technique for intraoperative margin assessment in BCS that could allow to reduce re-excision rate. This technique achieves both sufficient sensitivity and specificity with minimal disruption of intraoperative workflow.
Comparing conventional breast conserving surgery with the minimally invasive approach technique to treat early breast cancer - a retrospective case control study

Silvio Bromberg¹, Patricia Figueiredo¹ and Felipe Ades¹. ¹Hospital Israelita Albert Einstein, São Paulo, Brazil.

Background/Objective: The objective of the study was to compare the oncological safety and aesthetic results between the minimally invasive technique and the conventional breast conserving surgery. Breast conserving surgery was developed to avoid mastectomy and has become the standard of care in early stage breast cancer. Patient concerns with aesthetics have led to the development of oncoplastic surgical approaches. It has been demonstrated that the aesthetic success in breast cancer surgical treatment leads to improved sexual and social recovery. In patients that have no desire or no need for associated mammoplasty, minimally invasive treatments allow the maintenance of the breast pre-surgical appearance. The minimally invasive technique is an oncoplastic surgery aimed to remove both the breast tumor and the sentinel lymph node through one incision, thus providing better aesthetic results than the conventional breast conservative two incision technique.

Methods: We retrospectively evaluated 2 cohorts of 60 consecutive early breast cancer patients (invasive breast cancer measuring no more than 25mm and clinically axillary negative lymph nodes) operated by either conventional breast conserving surgery (N=26) or one incision surgery (N=34). We selected patients that have no desire or no need for associated mammoplasty. We compared the mammary volume tissue removed; surgical time; number of dissected lymph nodes; surgical complications such as seroma, infection, and dehiscence of the surgical wound; and deformities, retractions, and subsequent aesthetic sequelae.

Results: In the minimally invasive technique group the breast volume removed was significantly lower than in the conventional surgery technique group as well as was the surgical time and the number of dissected lymph nodes.

No cases required enlargement of the margins and aesthetical results were better in the minimally invasive technique with only incision group.

Conclusions: The minimally invasive approach to treat early breast cancer was shown to be similar to the conventional breast conserving surgery in terms of oncologic outcomes but providing better cosmetic result.
Breast conserving surgery by periareolar mammoplasty – Surgical and oncological outcomes

Rajaram Burrah¹, Raman Vinayagam¹ and Karen James¹. ¹Wirral University Teaching Hospital, Wirral, United Kingdom.

Background
Periareolar mammoplasty is a volume displacement oncoplastic technique for patients with small to medium sized breasts. This approach provides good access for a safe excision for both central and peripheral lesions, especially for those in the upper half of the breast. Cosmetically it allows good reshaping of the breast, and contralateral symmetrisation is rarely required. This technique has the potential to replace the standard wide local excision for breast cancer. There is scarcity of data about the results of this procedure in the literature. We present a single surgeon experience with this technique in terms of surgical and oncological outcomes.

Methods
Retrospective review of patients’ records from October 2013 to December 2017 was performed. The patients’ demographics, tumour characteristics and the early oncological outcomes were studied. The postoperative complications and rate of symmetrisation were also studied.

Results
-There were 110 patients in this study period. The median age was 60 years (range 36 – 82 years) and screen detected tumours accounted for 66% (72 patients) of cases.
-Neoadjuvant therapy was given in 14 patients (endocrine therapy – 12, chemotherapy – 1, dual targeted therapy – 1).
-Most patients had the lesion in the upper half of the breast (upper outer-71, upper inner-33).
-The average size of the tumour was 18.9mm (range 1.8 – 70mm) and the average weight of the excised specimen was 47.2gm (range 11-190gms). Invasive carcinoma was seen in 94 patients (85%) of which 86 patients had invasive ductal carcinoma, 4 had invasive lobular carcinoma and 4 had special type. Pure DCIS was present in 16 patients (15%). Most patients had grade 2 cancers (45%). DCIS was present with invasive carcinoma in 55% of cases.
-Thirteen patients had positive margins (<1mm) and DCIS coexisted with invasive carcinoma in 7 of 13 patients. Four patients with pure DCIS had positive margins.
-Of the 13 patients with positive margins: 5 required margin re-excision, 6 had completion mastectomy and 2 received only radiotherapy.
-The median follow-up was 25 months (range 3 – 53 months).
Seven patients developed complications which included 3 hematomas (2 requiring evacuation) and 4 wound infection which were treated with antibiotics. Only two patients required contralateral symmetrisation and no local recurrences were encountered in this study period.

Conclusion
Periareolar mammoplasty is a robust, easily adaptable and reproducible oncoplastic technique allowing for safe wide local excision of breast cancer. The margin re-excision, postoperative complication and recurrence rates in this study are acceptable and low compared to standard wide local excision. This technique gives excellent access, and allows better breast reshaping resulting in pleasing aesthetic outcome. Contralateral symmetrisation is rarely required with this technique.
Is radiofrequency ablation better than lumpectomy for margin status in breast cancer? Results of a randomized clinical trial

Amparo Garcia-Tejedor¹, Anna Guma¹, Teresa Soler¹, Alazne Valdivieso¹, Ana Petit¹, Nayanar Contreras¹, Cesar G Chappuis², Catalina Falò², Sonia Pernas², Ariel Anselem¹, Eulalia Fernandez-Montoli¹, Maria J Pla¹, Fernando Burdio³ and Jordi Ponce¹.
¹Hospital Universitari Bellvitge, Idibell, Hospitalet de Llobregat, Barcelona, Spain; ²Institut Català d'Oncologia, Hospital de Llobregat, Barcelona, Spain and ³Parc de Salut-Hospital del Mar, Barcelona, Spain.

PURPOSE: To study the safety and efficacy of ultrasound-guided percutaneous radiofrequency ablation (RFA) as local treatment for breast cancer and to intraoperatively evaluate the margin status after RFA in comparison with lumpectomy.

MATERIAL and METHODS: Preliminary in vitro RF ablation experimentation with two mastectomy specimens was performed to test the electrode, practice the ultrasound technique and evaluate the macroscopic and microscopic effects of RF. Then, a prospective, randomized open-label phase II clinical trial (NCT02281812) was conducted in a single institution from 2013-2017. Forty subjects, mean age 64 (range 46-86), with ductal infiltrating carcinoma of the breast ≤2 cm were randomly assigned to RFA plus lumpectomy or lumpectomy alone. Margin status, tumor cell viability (TCV) after RFA (by nicotinamide adenine dinucleotide (NADH) and Cytokeratin 18 (CK18) staining), adverse events and local recurrences were evaluated by univariable and multivariable analyses (SPSS statistical software).

RESULTS: In the experimental design with mastectomies, the only procedural complication was a skin burn at the entrance site of the electrodes. We learned that the tip of the electrodes should cut across the tumor by at least 10mm. The clinical trial includes two groups: study group (n=20) and control group (n=20). NADH and CK18 staining demonstrated absence of TCV after RFA with at least one of the two techniques. The percentage of intraoperatively affected surgical margins was higher in the control group although local adverse effects after surgery was higher in the RFA treatment arm. Three study subjects presented local infection (two had partial irradiation of the breast) and none in the control group.

RFA: radiofrequency ablation. n=number of subjects

Median follow up was 25 months (range 1–83). No recurrence or second surgery was required during the study period.

CONCLUSION: RFA seems effective in the cases considered and could be more accurate than lumpectomy in terms of obtaining more free margins. Surgical excision associated with RFA leads to a higher amount of local adverse effects, especially if combined with partial irradiation of the breast. RFA could be considered as a less invasive treatment in tumors smaller than 20 mm; however, this warrants further investigation.
Usefulness of periareolar zigzag incision in oncoplastic breast-conserving surgery

Beomseok Ko¹, Heejeong Kim¹, Ilyong Chung¹, Saebiyul Lee¹, Jisun Kim¹, Jongwon Lee¹, Byungho Son¹ and Sei Hyun Ahn¹.
¹Asan Medical Center, University of Ulsan, Seoul, Republic of Korea.

Background
Breast-conserving surgery (BCS) has been performed as a standard procedure because the addition of radiation therapy after breast-conserving surgery in early breast cancer patients is similar to that of mastectomy. The surgical methods for breast cancer have been developed in recent years, and the cosmetic aspect has become important. Several incisions are used to reduce the scar to the incision site during BCS. The periareolar incision is often used when the small tumor relatively close to the nipple. However, periareolar incision does not have sufficient field of sight, which can result in difficult or impossible operations if the tumor is large or far from the nipple. In plastic surgery, various methods such as zigzag incisions have been recommended to achieve satisfactory esthetic results. The periareolar zigzag incision has the advantage of a not only good surgical field but also contributed to better surgical scars. The purpose of this study was to evaluate the oncological safety of procedures by studying the status of the surgical margins of the excised tumor specimen and reduces the need for further surgery.

Methods
From January 2016 to November 2017, we conducted a survey of female patients who underwent BCS using zigzag incision. Patients with exclusion criteria were excluded from this study if they had a bilateral breast cancer or neoadjuvant chemotherapy was included in the study. Intraoperative frozen section margin was evaluated in all patients and additional resection was performed when the positive margin was present. Final margin status was determined by examination of the permanent paraffin-embedded sections. In patients with invasive breast cancer or relatively large carcinoma in situ, axillary surgery was performed according to the presence of axillary metastasis. Patients characteristics, tumor characteristics, operative time, size of the specimen and the distance from the tumor to nipple were evaluated.

Results
393 patients were enrolled in the study, including 9 patients with bilateral breast cancer, and a total of 402 cases of BCS surgery were analyzed. Thirty-five patients received neoadjuvant chemotherapy.

The median age of the patients was 51 (range: 25-84 years), the median time of operation was 72 minutes in patients who did not undergo axillary surgery or sentinel node biopsy only, and 83 minutes in patients who underwent axillary node dissection or supraclavicular node dissection. The median tumor size was 1.6 cm (range: 0.8-8.8 cm), median tumor distance from the nipple was 3.0 cm (range: 0.4-8.1 cm), mean excised specimen sized was 5.0 cm (range: 0.9-15.0 cm). Frozen biopsy of the resection margin during surgery revealed tumor-positive in 69 (17.2%) cases and re-excision was performed. All patients were discharged with no sign of infection or skin necrosis.

Conclusions
The periareolar zigzag incision technique has good cosmetic results and provides a sufficient surgical field, which can be useful for removing relatively large tumors or tumors far from the nipple.
Increased mortality with repeat lumpectomy alone after ipsilateral breast tumor recurrence: A propensity-adjusted, population-based SEER analysis

Yonghui Su\textsuperscript{1,2}, Rong Guo\textsuperscript{1,2}, Jingyan Xue\textsuperscript{1,2}, Yayun Chi\textsuperscript{1,2} and Jiong Wu\textsuperscript{1,2,3}. 1Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, China; 2Shanghai Medical College, Fudan University, Shanghai, China and 3Collaborative Innovation Center for Cancer Medicine, Shanghai, China.

Background: The benefit of repeat lumpectomy for ipsilateral breast tumor recurrence (IBTR) after breast conserving surgery (BCS) is currently inconclusive. This issue has become even more important as small and isolated recurrent tumors were frequently diagnosed.

Methods: IBTR patients with definitive surgery were identified in the Surveillance, Epidemiology, and End Results registry between 1973 and 2013. The effect of different IBTR surgeries on overall and cancer-specific mortality was assessed using risk-adjusted Cox proportional hazard regression modeling and stratified propensity score matching analysis (PSMA).

Results: Based on the selection criteria, 5098 patients were recruited. Of those, 4048 (79.4%) women underwent mastectomy and 1050 (20.1%) underwent repeat lumpectomy after IBTR. Patients who received repeat lumpectomy had lower grade (23.7% vs 15% for well-differentiated) and smaller recurrent tumor (47% vs 36.2% for ≤ 1 cm) but earlier recurrence (23.9% vs 11.2% for interval times < 48 months) than those who underwent mastectomy. A minority of each group (24.7% of those undergoing repeat lumpectomy and 3% of the mastectomy group) underwent RT after surgery. In multivariable Cox regression analysis, repeat lumpectomy was associated with increased overall mortality (Hazard ratio (HR) = 1.58, 95% CI = 1.353 to 1.844, \(P < 0.001\)) and cancer-specific mortality (HR = 1.721, 95% CI = 1.345 to 2.202, \(P < 0.001\)). Similar HRs were derived from the PSMA cohort. However, we found no significant difference in overall mortality for women who underwent repeat lumpectomy followed by RT compared with that for those who underwent mastectomy (\(P = 0.411\)). Moreover, IBTR patients with small tumors (≤ 1 cm) who underwent repeat lumpectomy with RT rather than without had similar overall and cancer-specific survival rates to those who underwent mastectomy (\(P = 0.189\) and \(P = 0.604\), respectively).

Conclusions: Our investigation suggests that compared with mastectomy, repeat lumpectomy for IBTR is associated with higher overall and cancer-specific mortality under real-world observational conditions. Furthermore, repeat lumpectomy with RT is equivalent to mastectomy with respect to overall mortality and may influence treatment decision making for patients with small IBTR.
Factors impacting surgical option in patients who achieved complete response in the breast after neoadjuvant systemic therapy

Hao-Wei Kou¹, Shih-Che Shen¹ and Shin-Cheh Chen¹. ¹Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Background:
Neoadjuvant systemic therapy (NST) is the standard treatment for locally advanced breast cancer. Early studies have demonstrated that the rate of breast conservation was significantly increased and NST is now widely applied to operable breast cancer to increase breast conservation rate and to achieve better cosmetic outcome after breast conservative surgery (BCS). For patients who achieved pathologic complete response (pCR), they were perfect candidate for BCS. However, data from prospectively randomized trials have shown that, with the significantly increase of pCR by adding new drugs in the neoadjuvant regimen, BCS rate does not significantly increased. The purpose of current study is to identify factors that have influence on surgical option in patients that have achieved complete response in the breast after NST.

Methods:
From January 2009 to July 2016, 1150 patients with breast cancer received NST in our institute. There were 103 patients achieved complete response (CR) in the breast and were included in current analysis. Medical records were reviewed regarding to individual surgeon, pre-NST clinicopathologic characteristics, and post-NST image findings. Risk factors for mastectomy were assessed by univariate and multivariate analyses.

Results:
Of the 103 patients who achieved CR in the breast, 40 of them (38.8%) received mastectomy. In univariate analysis, physician factor, larger initial tumor size, advanced clinical stages, as well as post-NST image findings including skin change, residual tumor ≥3 cm, short nipple-tumor distance, and residual axillary lymph node(LN) on ultrasound and segmental/diffuse distribution of malignant calcification on mammography were associated with more mastectomy. In multivariate analysis, physician factor (OR=5.192, CI [1.562 – 17.257], p=0.021), residual axillary LN on echography (OR=4.000, CI [1.552 – 10.319], p=0.004), and segmental/diffuse distribution of malignant calcification on mammography (OR=7.500, CI [1.819 – 30.916], p=0.018) were independently related to mastectomy in patients who achieved CR in the breast after NST.

Conclusion:
Physician factor, residual axillary LN and segmental/diffuse malignant calcifications were risk factors for mastectomy in patients who achieved CR in the breast after NST. In addition to embrace current treatment guidelines of surgical management after NST, our data provide valuable additional information to avoid unnecessary mastectomy.
The outcomes of ReFilx soft tissue filler as an immediate reconstruction technique for lumpectomy followed by radiotherapy

Wey Liang Leong¹, Kyle Battiston², Fred Cheung¹, Courtney Fulton¹, Alvin Lin¹, Wilfred Levin¹, Susan Done¹ and Paul Santerre². ¹University Health Network, Toronto, ON, Canada and ²Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, ON, Canada.

Introduction: Lumpectomy for breast cancer can often result in poor cosmetic outcomes which can lead to long-lasting impairment of quality of life. ReFilx is a synthetic porous degradable polyurethane scaffold that has mechanical properties comparable to that of native healthy breast tissue. It has been shown in two previous porcine studies to preserve breast shape and volume over 9 months when inserted into the cavities immediately after lumpectomy. We observed minimal foreign body reaction with good integration of the host tissue while the material degraded over time. In this study, we examined the healing process of lumpectomy treated with radiation. Radiotherapy is currently a standard adjuvant therapy after lumpectomy for breast cancers; and radiation is known to affect the healing process in general. Objective: To evaluate ReFilx, as soft tissue fillers for lumpectomy cavities in combination with standard radiotherapy. Hypothesis: ReFilx will preserve breast shape and volume by supporting tissue infiltration with minimal inflammation in the presence of clinically relevant radiotherapy. Methods: 3 female Yucatan minipigs received lumpectomies carried out using electrocautery to remove normal breast tissue of approximately 2 cm diameter, after which the cavities were filled with (case) or without ReFilx (sham control) (n=3 for each condition, each pig has 12-13 breasts). 6 weeks post-implantation, 2 of the pigs received radiation directed at the right half of their bodies (6 breasts per pig) for a total dose of 42.4 Gy delivered over 15 fractions using a clinical linear accelerator. The delivered doses to target sites and the adjacent tissue were confirmed with optically stimulated luminescent dosimeters (OSLDs). A third pig was maintained as a non-irradiated control. Ultrasound examinations were performed every 3 weeks post-implantation. At week 24 and 36, samples consisted of n=3 for irradiated and non-irradiated ReFilx and sham sites for the half-irradiated pigs, and n=3 for non-irradiated ReFilx and sham sites for the non-irradiated control pig were excised by mastectomy, the tissue samples were fixed in 10% buffered formalin for subsequent histological (H&E, Masson’s Trichrome) studies. Potential side effects were monitored by vital signs, pain control, wound checks, ultrasound and blood tests. Necropsies were performed at the conclusion of the study. Results: Ultrasound examination indicated no difference between ReFilx’s ability to maintain breast shape and volume with or without the presence of radiation treatment, in contrast to the collapse of the sham sites by 24 weeks. Similarly, the histology of irradiated and non-irradiated ReFilx samples showed similar levels of tissue infiltration, inflammatory changes and degradation of ReFilx. There was no significant side effects observed. Conclusions: ReFilx’s ability to act as a soft tissue filler for breast volume restoration post-lumpectomy does not appear to be significantly impacted by the presence of clinically relevant radiation treatment. Longer-term follow-up is currently in progress for this study. Acknowledgements: Connaught Innovation Award (University of Toronto) and Joule Innovation Fund (Canadian Medical Association).
The margin of breast-conserving surgery when ductal carcinoma *in situ* is present within invasive ductal carcinoma

Jie Chen¹,², Andrew Ro¹, Qiu-Wen Tan², Zu Wang² and Helena R Chang¹. ¹Revlon/UCLA Breast Center, David Geffen School of Medicine at University of California, Los Angeles and ²West China Hospital, Sichuan University, Chengdu, China.

Objective: The presence of ductal carcinoma *in situ* (DCIS) in invasive ductal carcinoma (IDC) may increase the rates of positive margins and re-excision. Literature addressing this association is limited. This study aimed to explore the factors that are associated with positive margins and re-excision, as well as to evaluate the influence of positive margins on the survival of patients with breast cancer containing both invasive and in situ ductal carcinoma.

Methods: A retrospective medical chart review of patients diagnosed with DCIS within IDC who underwent BCS at the Revlon/UCLA Breast Center between January 2003 and December 2008 was performed.

Results: Of the 488 eligible patients, 267 patients (53.9%) underwent re-excision. The presence of residual disease upon re-excision was the highest in patients who initially had positive margins involved by both DCIS and IDC. In multivariate analysis, calcifications, tumor size, positive lymph nodes, and the presence of extensive intraductal component (EIC) were significantly associated with initial positive margins, with the latter having the highest hazard ratio (HR, 5.5–5.7, *P* = 0.000). Tumor size, molecular subtype, and final margin status were associated with disease-free survival. The final margin and regional lymph node status are significant prognosticators for breast cancer-specific survival.

Conclusions: In patients with ductal carcinoma of the breast containing both invasive and in situ components, the rate of initial positive margin after BCS was high and was significantly associated with calcifications, tumor size, regional lymph node status, and the presence of EIC.
High-dose vitamin D supplementation for the correction of vitamin D insufficiency in patients undergoing adjuvant chemotherapy for breast cancer, a phase II multicenter study

William Jacot 1,2,3, Véronique D’Honct 1,3, Célia Touraine 1, Angélique Chapelle 4, Eric Legouffe 4, Manon Metge 5, Lobna Rifai 1, Lise Roca 1, Stéphane Poudouroux 1 and Gilles Romieu 1. 1ICM Val d’Aurelle, Montpellier, France; 2Montpellier University, Montpellier, France; 3INSERM U1194 – IRCM, Montpellier, France; 4Oncogard, Nîmes, France and 5Clinical Research Center, ICM Val d’Aurelle, Montpellier, France.

Background: Vitamin D (VitD) insufficiency affects most of patients with early breast cancer (EBC). Breast cancer treatment may lead to bone loss, due to premature ovarian failure or direct chemotherapy (CT) cytotoxic effects. These increase the risk of skeletal morbidity as compared to women without breast cancer history. We previously published the persistence of VitD insufficiency at the end of adjuvant CT despite an adapted dose supplementation. We report here the safety and efficacy analysis of a phase II trial evaluating a high-dose oral VitD supplementation regimen for correction of VitD insufficiency in insufficient EBC patients treated with adjuvant CT.

Material and methods: EBC patients with VitD insufficiency for whom adjuvant CT was planned were eligible for this study. They received one dose of 100,000 IU 25OH vitamin D every 3 weeks from day 1 of cycle 1 to day 1 of cycle 5, except in case of clinical or biological adverse event related to vitamin D and calcium metabolism, leading to early discontinuation. The primary endpoint was the percentage of serum 25OH vitamin D level normalization at day 1 of cycle 6 (D1C6). Secondary endpoints were the safety, the Vitamin D and calcium parameters (blood calcium, phosphorus and parathormone [PTH] levels, urinary calcium excretion) at baseline and the description of their evolution during adjuvant CT, as well as the evaluation of the predictive value of these biomarkers and baseline clinical factors on the percentage of VitD normalization at D1C6.

Results: Among 45 eligible patients, 44 were evaluable for the primary endpoint. Among them, 21 (47.7%; 95%CI: 33.0-62.8) achieved a 25OH-Vitamin D correction at D1C6. No clinical toxicity linked to the VitD treatment was reported. However, 13 patients (29.5%) presented an asymptomatic grade 1 hypercalciuria, possibly linked to the VitD treatment, without concomitant change in the kidney function, but which lead to the interruption of the high dose oral VitD supplementation in 10 of the 13 patients. VitD normalization rates at 6, 12, 18 and 24 months were 50, 28.9, 80 and 60.9%, respectively. No clinical or biological marker was found to significantly predict the 6-month 25OH vitamin D normalization.

Conclusions: A high-dose 25OH-vitamin D regimen allowed a high percentage of serum 25OHD level normalization at D1C6 in EBC patients undergoing adjuvant CT. An asymptomatic increase in urinary calcium excretion was observed in one third of the patients, without clinical consequences. The physiopathology of this urinary calcium increase warrants further evaluation, since it is a classical reason for VitD treatment interruption, leading to a lower rate of correction in this highly requiring clinical setting.
Upper extremity edema in the at-risk arm among patients receiving PI3K/mTOR/CDK4/6 inhibitors for metastatic breast cancer

Kayla M Daniell¹, Aditya Bardia¹, Fangdi Sun¹, Cheryl L Brunelle¹, Tessa C Gillespie¹, Hoda E Sayegh¹, George E Naoum¹, Steven J Isakoff¹, Dejan Juric¹ and Alphonse G Taghian¹. ¹Massachusetts General Hospital, Boston, MA.

Background: Targeted therapies, including mTOR and CDK 4/6 inhibitors, have changed the landscape of management of hormone receptor-positive (HR+) metastatic breast cancer (MBC). These therapies have shown significant improvement in progression-free survival and are generally well-tolerated. In pre-clinical models, modulation of the PI3K/mTOR pathway can impede lymphoangiogenesis resulting in capillary leakage. In this study, we examined the impact of PI3K, mTOR, and CDK 4/6 inhibitors in the development of upper extremity edema (UEE) in the at-risk arm for breast cancer-related lymphedema (BCRL) in patients with MBC.

Methods: We conducted a retrospective chart review of patients treated with PI3K/mTOR/CDK4/6 inhibitors for MBC. Clinicopathologic data including age, body-mass index (BMI), specific pathway targeted, treatment duration, and presence of edema were recorded. Characteristics of treatment including surgery type and laterality, nodal surgery, radiation regimen, and tumor subtype were also collected.

Results: Among patients with MBC treated with PI3K, mTOR, and/or CDK 4/6 inhibitors (N = 160), the incidence of edema that developed after initiation of the targeted therapy was 11.3% (18/160) for UEE and 31.9% (51/160) for edema in any anatomical location. 50.0% (11/22) of patients treated with a PI3K-a inhibitor, 32.6% (14/43) of patients treated with an mTOR inhibitor, and 33.3% (8/24) of patients treated with a CDK4/6 inhibitor alone developed peripheral edema following initiation of the respective targeted therapy. Further, swelling developed in the at-risk upper extremity after C1D1 in 13.6% (3/22) patients treated with a PI3K-α inhibitor exclusively, 7.0% (3/43) treated with an mTOR inhibitor exclusively, and in 12.5% (3/24) treated with a CDK4/6 inhibitor exclusively. Of the 42 patients treated with a CDK4/6 inhibitor in combination with either an mTOR inhibitor, aromatase inhibitor, or an ER-binding promoter, the incidence of UEE in the at-risk upper extremity after C1D1 was 18.8% (6/32), 0.0% (0/7), and 0.0% (0/3) respectively. In multivariate logistic regression analysis, both therapy with PI3K-a inhibitors (OR: 3.22; p = 0.049) and a relative decrease in serum albumin after 3 months of treatment (OR: 3.35, p = 0.024) increased the risk of developing peripheral edema; however, duration of therapy, and nodal surgery were not significant risk factors. Upon stratification of this cohort by number of BCRL-related risk factors, the incidence of BCRL was 18.3%, 39.5%, and 83.3% in women with one, two, or three BCRL-related risk factors, respectively.

Conclusions: PI3K, mTOR, and CDK 4/6 inhibitors may influence the development of UEE, which may cause or exacerbate progression of BCRL in at-risk arm among patients with MBC. Further research is needed to prospectively evaluate these novel findings as well as elucidate physiologic and clinical impacts of these therapies on peripheral edema and BRCL. Moreover, it is crucial to understand the role of close monitoring for the development or progression of peripheral edema or BCRL to ensure early detection and treatment, thus potentially minimizing the negative impacts on the quality of life of patients with MBC.
Changes in vitamin D and calcium metabolism markers in patients undergoing adjuvant chemotherapy for breast cancer

William Jacot1,2,3, Nelly Firmin1,3, Célia Touraine1, Stéphane Poudroux1, Marie Viala1, Manon Metge4, Lobna Rifai1, Gilles Romieu1, Lise Roca1, Séverine Guiu1,3 and Véronique D’Hondt1,3. 1ICM Val d’Aurelle, Montpellier, France; 2Montpellier University, Montpellier, France; 3INSERM U1194 – IRCM, Montpellier, France and 4Clinical Research Center, ICM Val d’Aurelle, Montpellier, France.

Background: Vitamin D (VitD) insufficiency affects the majority of patients with early breast cancer (EBC). Breast cancer treatment may lead to bone loss, due to premature ovarian failure or direct chemotherapy (CT) cytotoxic effects. These increase the risk of skeletal morbidity compared to women without breast cancer history. However, even if these evidences are well described, the evolution of calcium metabolism under CT is unknown in this population with a high cure rate. We report the evolution of VitD and calcium metabolism markers in patients undergoing adjuvant CT for EBC.

Material and methods: We evaluated the VitD and calcium parameters (blood calcium, phosphorus and parathormone [PTH] levels, urinary calcium excretion) in EBC patients treated with 6 cycles of adjuvant CT without high dose calcium and VitD treatment. Variables of interest were recorded at inclusion, then every 3 weeks, at each chemotherapy cycle initiation. Primary endpoint was the occurrence of a hypercalciuria during the course of adjuvant CT (between Day 1, Cycle 1 [D1C1] and Day 1, Cycle 6 [D1C6]).

Results: 82 patients were evaluable for the primary endpoint. The median age was 53 years (range 20-71). CT consisted of a sequential anthracyclines and taxane regimen in 96.3% of the cases. Eleven (26.8%) patients received adjuvant trastuzumab. Most patients (66, 80.5%) presented with baseline VitD insufficiency (<30 ng/mL). Median baseline VitD level was 20.65ng/mL (range 2.9-55). Nine patients (8 VitD insufficient, 1 VitD sufficient [calcium only]) received low-dose VitD and/or calcium supplementation during the CT cycles. No baseline clinical parameter was statistically predictive of a VitD baseline insufficiency, while baseline blood calcium level was statistically predictive of a VitD baseline insufficiency (p=0.051). 94% of the patients presented with VitD insufficiency at D1C6 (median VitD level 20ng/mL; 9-39). No case of hypercalcemia was recorded. 29 patients (35.4%; 95%CI: 25.6-46.5) developed hypercalciuria between D1C1 and D1C6, none clinically significant. This percentage was not significantly different between VitD insufficient patients and the others (34.8% vs. 37.5%), nor between supplemented and not supplemented patients (37.5% vs. 34.5%). In multivariate analysis, weight and BMI were significantly associated with the occurrence of a hypercalciuria, while a trend was detected for baseline VitD (p=0.085) and albumin blood level (p=0.072). Baseline PTH level was elevated in 12.7% of the VitD insufficient patients vs. none of the patients with a normal VitD level. These percentages increased to 52.5% and 50% respectively at D1C6.

Conclusions: We report here, to our knowledge, the first comprehensive study of the kinetics of VitD and calcium biomarkers during EBC adjuvant CT. This population appears highly VitD insufficient, with a compensatory elevation in blood PTH levels during the course of treatment. Hypercalciuria, while asymptomatic, is a highly prevalent abnormality in this setting, and must not be a limitation for high dose VitD supplementation.
Prevention of lymphedema in patients undergoing axillary dissection for breast cancer by benzathine penicillin: A non-inferiority randomised controlled trial

Kavindra Singh¹, Anita Dhar¹, Anurag Srivastava¹, Piyush Ranjan¹, Kamal Kataria¹ and Kaustubha S Gour¹. ¹All India Institute of Medical Sciences, New Delhi, Delhi, India.

Background: Axillary lymph node dissection (ALND) is performed for axillary lymph nodal metastasis. Major complication of ALND is lymphedema. Lymphedema is a morbid condition associated with impaired activities of daily life and deterioration in quality of life (QOL). Olszewski et al (Lymphology. 2005 Jun;38(2):66–80) have shown that low-grade staphylococcal infection is a risk factor for lymphedema. Hence, we embarked upon a randomised controlled trial with non-inferiority hypothesis to evaluate efficacy of injection Benzathine penicillin in preventing breast cancer related lymphedema.

Methods: In this 2 group, open label, parallel design randomized controlled trial; patients undergoing ALND for breast cancer were included. Patients were randomized using block randomization to either injection Benzathine penicillin group or in control group. Patients in the penicillin group received injection Benzathine penicillin 1.2 million units as deep intramuscular injection after antibiotic sensitivity testing at intervals of 3 weeks. Primary endpoint was development of lymphedema at 6 months follow up. Analyses were done on an intention to treat basis. Lymphedema was defined as increase in >200ml of volume on water displacement method and or increase in arm circumference of >2cm from pre surgery values (Lancet Oncol. 2013 May 1;14(6):500–15).

Findings: Between July 2016 and December 2017, 83 ladies were randomly allocated, 40 in the penicillin group and 43 in control group. At 6 months follow up; a total of 15 (18.07%) patients had lymphedema. Out of them 5 patients were in penicillin group and 10 in the control group. Cellulitis was seen in 2/3rd of patients (10 out of 15) having lymphedema. The relative risk of cellulitis in penicillin group was 0.119 with 95% CI of (0.016-0.901) and prevented fraction of 0.881

Comparison of lymphedema and cellulitis in two groups

RR: Relative risk, PF: Prevented fraction, CI: Confidence interval

Other factors like radiotherapy, type of surgery for primary tumor, extent of axillary dissection and type of chemotherapy were comparable in both groups. None of the patients receiving penicillin have any adverse effect or allergic reaction to the drug during the study period.

Conclusion: Penicillin administration in patients undergoing axillary lymph node dissection is safe and significantly reduces risk of lymphedema and cellulitis.

Novelty: This is the first randomised trial demonstrating the benefit of long term administration of penicillin in reducing lymphedema and cellulitis.
Accurately monitoring by specialist teams reduces the time between breast cancer screening and initial surgical treatment

Kim Neff¹ and Cary S Kaufman². ¹Leica Biosystems, Cincinnati, OH and ²National Consortium of Breast Centers, Warsaw, IN.

Background
Over 266,000 women are newly diagnosed with breast cancer every year in the United States, roughly 21% of women die of the disease annually.[1] Many studies have been conducted to evaluate how delays in diagnosis and treatment can result in adverse patient outcomes. Factors including tumor size and stage, socioeconomic status, race/ethnicity, and hospital size and capabilities have been shown to influence outcomes.

Variation in care delivery and turnaround times can be reduced by accurately examining the patient care path from initial screening mammography to first surgical intervention. We have developed a process to optimize timeliness to initial surgical treatment.

Methods
The process starts with observing care delivery from diagnostic mammogram, biopsy, pathology tissue processing, diagnosis and lumpectomy or mastectomy.

A team of process and clinical experts (Leica Biosystems) conducted observations to map out current care delivery processes. Standard national metrics for timeliness within the breast care pathway from the National Consortium of Breast Centers' was applied to the process map to understand national averages as well as best practices. Timeliness data on 5,571 patients from over 250 breast centers across the country from the NQMBC (National Quality Measures for Breast Centers) database was utilized to review time intervals and intradepartmental hand offs that impact progression through the breast care pathway.

Six sigma, black belt specialists conduct analysis of current breast center processes, identifies specific sites for improvement, integrates their recommendations and completes the cycle by repeat monitoring of the entire process.

Results
Our specialists have reviewed average and ideal overall performance in timeliness to initial surgical treatment. Improvements may be expected from 22%-75% in timeliness to initial surgical treatment.

</tbody>
</table>

* Mean=average number of business days based on NQMBC data July-Dec. 2017
** “Best Practice”=The 75th percentile based on data in NQMBC database July-Dec. 2017

Conclusion
A process to impact the timeliness of care between screening mammography and initial surgical treatment has been developed. Standardized and monitored care delivery processes can result in better efficiency in breast cancer patient care delivery from between 22% - 75%. Using a detailed patient care pathway and black belt specialists to analyze processes, we expect to reduce turnaround times and optimize efficiency across the breast cancer patient’s care pathway.

Concordance assessment of IBM Watson for Oncology with MDT in patients with breast cancer

Junnan Xu¹, Tao Sun¹ and Songyuan Hua². ¹Liaoning Cancer Hospital & Institute, Shenyang, China and ²Hangzhou Cognitive Care Technology Co., Ltd., Hangzhou, China.

Objective: IBM Watson for Oncology (WFO) is an artificial intelligence cognitive clinical decision support system which provides evidence-based treatment recommendations in cancer. This study aimed to examine the level of agreement (concordance) between treatment recommendations made by WFO and a multidisciplinary tumor (MDT) board for adjuvant therapy in early stage breast cancer and first-line therapy in metastatic breast cancer.

Methods: Treatment recommendations were provided by WFO and MDT board for 92 early stage and 40 metastatic breast cancer cases between Jan 2017 and Jan 2018. WFO treatment recommendations were provided in 3 categories: “Recommended”, “For Consideration” and “Not Recommended.” It was considered concordant if the tumor board recommendations were designated ‘recommended’ or ‘for consideration’ by WFO Version 17.10.

Results: Overall treatment concordance between WFO and MDT was 76.51%, 73 cases with early stage breast cancer (79.35%) and 28 cases with metastatic breast cancer (70.00%) we concordant. Among all the 132 cases, 49 cases were in ‘Recommended’ category, 52 cases were in ‘for consideration’ category, and 26 cases were disconcordant. Subgroup analysis found that patients with stageIIIdisease or triple-negative breast cancer were the most likely to be concordant. Luminal A type and HER2-positive cases were less likely to be concordant than other types. In early stage breast cancer, based on the low recurrence risk, 11 cases and 2 cases were treated with TC and EC regimen instead of AC-T or CMF regimen recommended by WFO. 4 patients with HER2-positive were disconcordance by using TCbH or AC-TH regimen instead of AC-TH or CMFH regimen recommended by WFO. The main reason of disconcordance in metastatic cancer was that CDK4/6 inhibitors had not been approved in China.

Conclusion: Treatment recommendations made by WFO and the tumor board showed highly concordant in breast cancer. Cancer stage and subtype had significant influence on concordance, and Watson for Oncology need to be optimized in localization.
Evaluation of the effects of talazoparib on QT interval prolongation

Justin Hoffman¹, Jayeta Chakrabarti², Zev A Wainberg³, Anna Plotka⁴, Sunil Babu⁵, Adriana Milillo Naraine⁶, David Kanamori⁷, Rebecca Moroose⁸, Linh Nguyen⁹ and Diane Wang¹. ¹Pfizer, Inc., La Jolla, CA; ²Pfizer, Inc., Tadworth, United Kingdom; ³University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; ⁴Pfizer, Inc., Collegeville, PA; ⁵Fort Wayne Medical Oncology and Hematology, Inc., Fort Wayne, IN; ⁶Memorial Cancer Institute at Memorial Regional Hospital, Hollywood, FL; ⁷Comprehensive Blood and Cancer Center, Bakersfield, CA; ⁸Orlando Health, Inc., Orlando, FL and ⁹Pfizer, Inc., San Francisco, CA.

Background: Talazoparib (TAL), an oral poly ADP-ribose polymerase inhibitor, is under investigation in multiple oncologic clinical trials and has been submitted to the US FDA for use in patients (pts) with germline BRCA-mutated, HER2-negative advanced breast cancer. International Conference on Harmonisation guidance recommends all new drugs be evaluated for effects on cardiac repolarization in a well-controlled clinical study. For drugs for which such evaluation cannot be conducted in healthy volunteers (eg, most anticancer agents), collection of robust corrected QT (QTc) interval data from a dedicated QTc study (hybrid thorough QT/QTc study) in pts is required in the registration dossier. The effect of steady-state (ss) TAL (1 mg once daily) on cardiac repolarization in pts with advanced solid tumors was evaluated in an open-label phase 1 study (NCT03042910).

Methods: Continuous 12-lead electrocardiogram (ECG) recordings were collected at baseline (Day -1); time-matched pharmacokinetic (PK) samples and continuous ECG recordings were obtained on Days 1, 2, and 22 (when TAL concentrations achieved ss). On Day -1, pts had continuous 12-lead ECG recording starting at Time 0 (Day 1 dosing time) for 6 hrs. On Days 1 and 22, ECG recording started 45 min before TAL administration and continued for 6 hrs post dose and blood samples for PK were collected before dose and at 1, 2, 4, and 6 hrs post dose. On Day 2, a 30-min ECG recording and a PK sample were obtained before dose at Time 0.

Continuous ECG recordings were submitted to a central laboratory; triplicate 10-sec ECGs were extracted from a 5-min extraction window beginning 15 min before each PK collection time. ECG measurements were reported via blinded manual adjudication process and included PR interval, QT interval, RR interval, and QRS complex. The QT interval was corrected for effect of heart rate using Fridericia's correction (QTcF) and Bazett's correction (QTcB).

The estimate of change from time-matched baseline and its 2-sided 90% confidence interval (CI) was calculated for each nominal time point using PROC MEANS. Additionally, a prespecified PK/pharmacodynamic (PD) model was used to describe the relationship between plasma TAL concentrations ([TAL]) and QTc. The prespecified linear mixed-effects model included [TAL], time (categorical), and treatment with random pt effects on [TAL] and the intercept. If the upper bounds (UB) of 1-sided 95% CIs of time-matched ΔQTc for all ECG time points were <20 msec and the UB of 1-sided 95% CIs of the predicted ΔQTc at the mean ss maximum [TAL] was <20 msec, the effect of TAL on QTc was not of clinical relevance.

Results: 37 of 38 pts enrolled received TAL and were included in the ECG and PK/PD analyses. No pts had a postbaseline absolute maximum QTcF or QTcB ≥500 msec or ΔQTc ≥60 msec. The UB of the 1-sided 95% CI for the time-matched ΔQTcF and ΔQTcB were <12 msec at all nominal ECG time points. In the PK/PD analysis, the slopes (95% CI) of QTcF-[TAL] and QTcB-[TAL] relationships were -0.14 (-0.78 to 0.50) msec/ng/mL and -0.24 (-0.88 to 0.41) msec/ng/mL, respectively, indicating that TAL did not have a concentration-dependent effect on QTcF or QTcB.

Conclusion: TAL does not have a clinically relevant effect on QTc.

Preclinical and clinical evidence about the use of betablockers for the treatment of triple negative breast cancer: A systematic review

Andrea Spini\(^1\), Giuseppe Roberto\(^2\), Rosa Gini\(^2\), Claudia Bartolini\(^2\), Lorenzo Bazzani\(^1\), Sandra Donnini\(^1\), Sergio Crispino\(^3,4\) and Marina Ziche\(^1\). \(^1\)University of Siena, Siena, Italy; \(^2\)Agenzia Regionale di Sanità Toscana, Florence, Italy; \(^3\)ASSO, Siena, Italy and \(^4\)Anticancer Fund Brussels, Brussel, Belgium.

Introduction
Triple negative breast cancer (TNBC) is a particularly aggressive subtype of breast cancer (BC) for which very limited therapeutic options are available. Recently, beta-blockers (BB) have been suggested to have favorable effects on the treatment of BC both in preclinical and clinical studies.

Objective
The aim of this systematic review was to collect evidence from preclinical and clinical studies concerning the scientific evidence for the repurposing of BBs in TNBC treatment.

Methods
PubMed database was searched for retrieving studies of interest published up to 30/01/2018. All preclinical studies using BC in vitro and in vivo models and assessing the effect of any molecule with sympatholytic or sympathomimetic activity on adrenoceptors were included. Clinical studies concerning BB were considered eligible. Two authors independently reviewed and screened title and abstract of retrieved references. Potentially relevant studies were further assessed through full-texts examination. One author extracted information from preclinical and clinical studies respectively. A second author subsequently reviewed the extracted data. The Newcastle-Ottawa scale was used for the quality assessment of clinical studies.

Results
A total of 616 study references were initially retrieved. Six additional records were retrieved through snowball search. A total of 62 preclinical studies were included, of which 46 concerned in vitro and in vivo models of TNBC, i.e. cell cultures and/or animal studies (20 in vitro, 9 in vivo, and 17 in vivo/vitro). In vitro studies showed a high expression of β\(^2\) adrenoreceptors in TNBC cell lines. Propranolol, a non-selective β\(^1\)/β\(^2\) antagonist, was reported to significantly decrease proliferation, migration and invasion of TNBC cells. Similar effects were also reported for carvedilol, a selective β\(^2\) antagonist and α\(^1\) antagonist. In vivo studies reported a reduction of metastasis, angiogenesis and tumor growth in animals exposed to propranolol. Clinical studies, reporting evidence from a total of four distinct retrospective observational cohort studies, showed a beneficial effect of BB in TNBC treatment: e.g. study#1: Overall Survival Hazard Ratio (HR)=0.35 (95%CI 0.12-1.00); study#2: metastasis HR=0.32 (95%CI 0.12–0.90); study#3 Progression Free Survival: HR=0.52 (95%CI 0.34–0.79); study #4 Relapse Free Survival: HR=0.69 (95%CI 0.35–1.34). The overall quality of the clinical evidence collected was low.

Conclusion:
Preclinical evidence collected in this systematic review are in line with the results reported in the four clinical studies retrieved, pointing towards a beneficial effect of BB in the treatment of TNBC. However, given the overall low quality of available evidence, no definite conclusion may be drawn. The execution of large scale interventional clinical studies are warranted to shed light on the efficacy/effectiveness of BB in TNBC treatment.

Hyperglycemia secondary to everolimus is associated with a prognosis improvement in hormone-sensitive metastatic breast cancer. A retrospective analysis

Sergio Sandiego¹, María Asunción Algarra¹, Héctor Augusto Aguilar¹, Pablo Álvarez¹, Ángel Guerrero¹, Joaquín Gavilà¹, Virtudes Soriano¹, Salvador Blanch¹, Vicente Guillem¹ and Amparo Ruiz¹. ¹Instituto Valenciano de Oncología, Valencia, Spain.

Introduction
The Everolimus and Exemestane combination improves PFS (progression-free survival) in patients with metastatic hormone-sensitive breast cancer pre-treated with aromatase inhibitors (BOLERO-2). However, such combination is associated with an increase in the rate of adverse events compared to monotherapy with Exemestane.

Patients and Methods
We selected female patients diagnosed in our center from hormone-sensitive metastatic breast cancer who were treated with the combination of Everolimus 10mg plus Exemestane 25mg between January 2012 and June 2018 (n=84). In these patients, we analyzed the number and grade of adverse events, as well as the correlation between each adverse event and the PFS.

Results
As patient characteristics, median age was 61 years old. 39.3% had bone metastases at the diagnosis of metastatic disease, 14.3% had visceral metastases and 46.4% had visceral and bone metastases. They had received a median of 2 treatments for advanced disease (including chemotherapy or hormonotherapy) previous to Exemestane and Everolimus, and at least 2 months of the combination treatment. Median SLP was 6 months.

AE’s in IVO patients (n=84)

</tbody>
</table>
In the univariate analysis, we see a statistically significant correlation between the presence of hyperglycemia and an improvement in PFS.

In the multivariate analysis using all AE’s, impact of hyperglycemia in SLP remained statistically significant (SLP for variable Hyperglycemia has a p-value of 0,014 and 0,531 Exp(B)

**Conclusions**

In our experience, mucositis is the most frequent AE in patients treated with the combination, followed by fatigue and hyperglycemia. Moreover, it seems to be a correlation between the apparition of hyperglycemia and better PFS. It’s well known that mTORc1 (target of Everolimus) has an important role in glycolisis: maybe the development of hyperglycemia is an indirect data from a better target inhibition. Analysis between other biological and tumor factors and their impact on survival is ongoing.
Intralesional steroid injection: A novel method to treat the symptoms of idiopathic granulomatous mastitis

Deborah J Manst, Denisse Gil, Paul Mullarkey, Elizabeth A Marcus and Pamela S Ganschow. Cook County Health & Hospitals System, Chicago, IL.

Background: Idiopathic granulomatous mastitis (IGM) is a chronic, inflammatory breast condition of benign nature that can clinically mimic breast cancer. Patients frequently present with a large, painful breast mass with associated inflammatory changes of the skin, and possible ulceration or fistula of the breast. Attempted methods for symptomatic relief include surgical excision and medical therapies including oral corticosteroids. Due to the success of treating dermatologic conditions with intralesional steroid injections, it was hypothesized that injecting the subdermal lesions of IGM may benefit patients with this disease. The use of intralesional steroid injections for the treatment of IGM has not been previously described in the literature.

Methods: Retrospective chart review was performed on a series of four patients with IGM who received intralesional steroid injections between August 2017 and April 2018. Patients were selected for treatment with injections based on their subjective report of painful breast lesions, lesion characteristics including size and depth, and the patient's desire to stop oral steroid therapy due to side effects despite active or residual disease. Data were collected on demographics, initial physical examination findings, prior and current treatments, characteristics of disease, details of injections performed, objective and subjective response to treatment, and recurrence.

Results: All patients presented with breast pain and either a mass, swelling, or hardness of the breast. Each patient received between one and three injection treatments, with one to four lesions treated in each session. Patients demonstrated improvement in subjective and objective symptoms after 87.5% of injection sessions (7 out of 8) by the subsequent follow-up visit (21-34 days). During the study period, three patients experienced resolution of at least one breast lesion within about 2 months (31-139 days, mean 68 days) without recurrence. One patient had four breast lesions that completely resolved (35-217 days, mean 88 days), but three of them recurred (63-217 days, mean 149 days).

Conclusion: In a small group of patients with idiopathic granulomatous mastitis, intralesional steroid injections were associated with an improvement in both subjective symptomatic relief and objective breast lesion characteristics in most cases. This treatment was associated with a good rate of lesion resolution and a low short-term recurrence rate.
Metastatic breast cancer: A retrospective study of clinical trials versus standard therapy

Nithya Sritharan¹, Marie Tuft², Margaret Q Rosenzweig³ and Rachel C Jankowitz⁴. ¹UPMC Mercy, Pittsburgh, PA; ²University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA; ³University of Pittsburgh, Pittsburgh, PA and ⁴University of Pittsburgh School of Medicine, UPMC Hillman Cancer Center, Pittsburgh, PA.

Background: Breast cancer is a leading cause of death in women. Metastatic breast cancer (MBC) was the leading cause of death among the 41,000 patients with breast cancer who died this year. The number of available clinical trials for breast cancer patients has dramatically increased over the last two decades, yet recruitment to trials remains low. To better understand the characteristics of women with MBC who agree to participate in clinical trials (CT) as compared to those who do not, control (C), we:

1. Compared the characteristics (age, race, tumor characteristics, and disease course) of women with MBC in the groups CT and C.
2. Compared the outcomes of women with MBC (metastatic survival), who enrolled in a clinical trial vs those who did not.
3. Noted the predictors for poor MBC survival overall.

Methods: Patients with MBC, from the year 2000 to 2017, were analysed retrospectively from an established metastatic database at our institution. Characteristics and outcomes were compared for patients enrolled in clinical trials (CT) with patients who were not enrolled in any trials (C). Characteristics included race, receptor status (ER/Her2), site of initial metastasis, presence of visceral and/ or CNS metastasis, number of chemotherapy and metastatic hormonal therapy cycles. Comparison of groups utilized the Chi-square test for proportions and Student’s T test for means. Univariable and multivariable associations with survival were analysed using Cox regression.

Results: Of the 660 patients, 249 enrolled in clinical trial (CT) and 411 served as controls (C). Demographic analysis showed that the age at first metastasis was identical in both the groups (52.8 ± 11.4 in CT and 53.8 ± 11.2 in C). Racial distribution was predominantly Caucasian, n= 92% (CT) vs n= 89% (C), with African Americans forming 4.5% (n=11) and 8.3% (n=34) in the respective non-Caucasians in the CT and C groups (p= 0.13). No significant differences were noted between CT and C groups in the proportion of CNS metastasis, receptor status (ER/Her2), initial site of metastasis (visceral/ non-visceral), number of cycles of chemotherapy or a diagnosis of de novo metastatic disease. The proportion of patients with visceral metastases was higher in the CT patients (82.3%) vs. (71.3%) (p < 0.012). Mortality was noted to be higher in the CT group (85.9%), when compared to C (73.2%), measured over the study duration.

Survival from the diagnosis of metastatic disease was not significantly different between CT and C patients. Worse survival outcome overall was noted in patients with triple negative disease (HR 1.7, p < 0.0001), presence of visceral metastases (HR 1.6, 2.0 and 1.9 for 1, 2 and 3+ visceral metastases respectively (p < 0.0001) and CNS metastases (HR 1.5, p < 0.0001) in the CT group.

Conclusion: No significant demographic differences were identified between the patients enrolled in CT vs C. Higher mortality was noted in the CT group over the study duration of 17 years. The CT group had a higher number of patients with visceral metastases, but lower CNS metastases as expected for clinical trial enrolment. Although no survival difference was identified based on trial enrolment, worse outcomes were seen in patients with triple negative disease, presence of visceral or CNS metastases.
Introduction: Latin America (LATAM) is among the so-called emerging regions for conducting clinical trials. Complex not-harmonized regulatory frameworks and lengthy approval timelines (among other factors) present challenges for increased LATAM trial participation.

Objective: to assess LATAM contribution to clinical trials, we conducted a descriptive analysis of the region participation in practice-changing breast cancer (BC) trials.

Methodology: we defined practice-changing trial as any one that supported FDA approval of a new drug or a new indication for a previously approved drug; we excluded trials that only led to approval of changes in regimen/doses. Through the FDA website we searched all drugs approved for BC treatment between January 1992 and December 2017. For each FDA-approved drug we identified applicable practice-changing trials in the latest package insert. We analyzed each applicable published article for data of interest: drug approval year, indication, participating countries, number of sites per country, trial start year of enrollment, authors per country, among others. If all these data was not available in the article we searched for it in clinicaltrials.gov. If all data was neither in the article nor clinicaltrials.gov, the trial was excluded from our analysis.

Results: 31 trials that led to the approval of 17 drugs were included in our analysis. LATAM participated in 21 trials (67.7%), mean number of LATAM countries per trial = 3.3 and mean number of sites per trial = 13.5. The region participated in 90% of (neo)adjuvant and in 57% of metastatic trials. Additional data is in Table 1. As an average, LATAM contributed with 4.9% of all trial sites. Argentina, Brazil and Mexico had 84% of LATAM sites, Peru and Colombia 8%, and the remaining 8% were distributed among 15 LATAM countries. The 5-year periods with highest number of trials in the region was 2001-05 and 2006-10 (Table 2). Fifteen LATAM authors (87% from Argentina and Brazil) from a total of 530 authors (2.8%) were identified in the primary publication, none of them as first or last author.

Conclusion: over the last 25 years the number of practice-changing BC trials conducted in LATAM has increased since 1990s, remained stable from 2001-10 and recently decreased. LATAM participated in the majority of (neo)adjuvant trials; longer time for enrollment and duration of these trials could explain this finding since these would allow for inclusion of regions with longer regulatory timelines. Region’s contribution in terms of countries, sites and authors is minor. Disparities within LATAM countries are remarkable and, as expected, the 3 largest countries are the key contributors. A comparison with other emerging regions will be presented.

Responding at patient's time of need: Scaling rapid access to evidence-based treatment plans

Naresh Ramarajan¹, Ramarajan Srivastava¹, Farzana Begum¹, Sudeep Gupta², CS Pramesh³ and Rajendra Badwe³. ¹Navya Network, Cambridge, MA; ²Breast Disease Management Group, Tata Memorial Centre, Mumbai, India and ³Tata Memorial Centre, Mumbai, India.

Background: Cancer patients worldwide feel intense anxiety, often racing to start treatments at non expert centers. Further, imbalanced oncologist to patient ratios (~1600: 1.8 M in India, ~23,000: 15M in USA), impedes access to expertise. We study the impact of rapid evidence based expert treatment plans in relieving patient anxiety. Navya, a health services technology, generates personalized treatment plans that maps within NCCN Resource Stratified Guidelines [SABCS 2017]. This is vetted on mobile by oncologists at tertiary centers like TMC NCG to provide expert opinion reports to patients. Since 2015, ~19,457 patients from 57 countries have reached out for an online opinion. On the ground, 78% of patients received evidence based treatments recommended by Navya [ASCO 2017].

Methods: To assess impact of timeliness, a prospective series of patients (from Sep '17 to April '18) were asked: “Were you relieved to receive expert opinion report in [x] days?” “Does it matter to you to receive expert opinion report in 1 day?” To assess time savings, preliminary reports with treatment options from NCCN and TMC NCG guidelines were shared with patients who matched all guidelines criteria. Subsequently, expert opinion reports were shared as usual.

Results: 543/701 patients responded to phone follow-up. 97% [± 3.2] were relieved to receive expert opinion reports in 1-2 days (103/106) vs 83% [± 3.8 ] for 3+ days (365/437). Of those not relieved by 3+ day turnaround, 83% stated that it would matter to receive expert opinion reports in 1 day (60/72). The first 300 preliminary reports shared in median time of 3.37 hours, resulted in 90% time savings vs expert opinion reports. On 10% of the preliminary reports, experts added information such as de-/escalating therapy (18/31), and additional diagnostic tests (6/31).

Conclusions: Navya relieves patient anxieties by responding at the time of need with evidence based treatment plans. Scaling such health services technologies to patients worldwide is feasible.
Voice of cancer patient: Analysis of breast cancer patients’ experience with PARP inhibitors

Sangeeta Aggarwal¹, Rishi Sharma², Manish Singh² and Alok Aggarwal³. ¹Santa Clara Valley Medical Center, San Jose, CA; ²Scry Analytics India Pvt. Ltd., Gurgaon, Harayana, India and ³Scry Analytics INC, San Jose, CA.

Background:
Many breast and ovarian cancer patients have germline or somatic mutations in BRCA 1&2 genes. These proteins are important for repairing double-strand DNA breaks by homologous recombinational repair. In patients who have mutations in these genes, PARP is the major alternative for repairing single-strand DNA breaks. PARP inhibitors (PARPi) inhibit PARP, thereby causing cell death by accumulation of damaged DNA in cells. Many PARPi, including Olaparib, have been approved and used in treatment of metastatic ovarian cancer patients with BRCA 1&2 mutation. Recently, Olaparib was also approved by the FDA for treatment of metastatic breast cancer patients with germline BRCA 1&2 mutation, and many other PARPi are in clinical trial. In this study we analyzed breast cancer patients’ awareness, use and experience with PARPi’s.

Many patients share their experiences on online forums which contain millions of freely shared messages. These can be used to analyze patient concerns and experiences. However, this data is unstructured and difficult to analyze. We used our automated system VoCP, that uses techniques from Big Data Science and Artificial Intelligence (deep learning, topic modeling, information retrieval, and natural language processing) to analyze these messages.

Methods:
We collected 15.13 million unique messages by 987,189 users from 37 unrestricted cancer forums that provide clinically relevant information. We built custom ontologies for breast cancer, various PARPi, chemotherapy and side effects, and then used our automated system VoCP to extract relevant information from these messages.

Results:
We found 1,536 breast cancer patients discussing PARPi. 459 patients mentioned use of PARPi whereas 706 patients shared the information about PARPi and 196 inquired about them. 176 patients mentioned that they were planning to use PARPi. 76 patients using PARPi mentioned having BRCA 1 or 2 mutation and 1 patient mentioned CHEK 2 mutation. 91 patients mentioned having triple negative cancer.

212 patients mentioned being treated on clinical trial and 10 mentioned being off trial. 162 patients mentioned use of chemotherapy with PARPi and 40 mentioned use of PARPi as single agent.

Specific PARPi: 47 mentioned Olaparib, 104 mentioned Valiparib, & Talazoparib, 6 rucaparib and 4 Niraparib. Most patient just mentioned “PARP inhibitor.” Some patients mentioned iniparib on clinical trial.

Side effects were reported by 60 patients. These include:
· Nausea: 14
· Fatigue: 15
· GI side effect: 7
· Thrombocytopenia: 5
· Anemia: 2
· Neutropenia: 2
· Neuropathy: 5
· Insomnia: 2

99 patients mentioned PARPi were “effective,” 21 mentioned they were “somewhat effective” and 36 mentioned they were “ineffective.”

144 patient expressed positive sentiments, 30 patients expressed negative sentiments and 16 patients expressed neutral sentiment for PARPi.

Conclusion:
· There is increasing awareness and curiosity for PARPi in breast cancer patients as more patients are being tested for BRCA and other mutations.
· Among the users, PARPi are generally associated with low toxicity and positive sentiments.
VoCP reliably provides meaningful insights from the patient's point of view; it also gives insight into unmet needs where more resources and research should be focused.
Molecular residual disease detection with circulating tumor DNA analysis predicts relapse in patients with early stage breast cancer

Nicholas Turner¹, Isaac Garcia-Murillas¹, Neha Chopra¹, Iñaki Comino-Mendez¹, Matthew Beaney¹, Holly Tovey¹, Ross Cutts¹, Claire Swift¹, Divya Kriplani¹, Maria Afentakis¹, Sarah Hrebien¹, Giselle Walsh¹, Stephen Johnston², Alistair Ring², Simon Russell³, Abigail Evans⁴, Anthony Skene⁵, Duncan Wheatley⁶, Mitch Dowsett¹ and Ian Smith². ¹The Institute of Cancer Research, London, United Kingdom; ²The Royal Marsden Hospital, London, United Kingdom; ³Hinchingbrooke Hospital, Huntingdon, United Kingdom; ⁴Poole General Hospital, Poole, United Kingdom; ⁵Royal Bournemouth Hospital, Bournemouth, United Kingdom and ⁶Royal Cornwall Hospitals NHS Trust, Truro, United Kingdom.

Background. Detection of circulating tumor DNA (ctDNA) after treatment of early stage breast cancer may identify molecular residual disease. In a prior proof-of-principle study we demonstrated that detection of ctDNA predicted relapse with high accuracy (Garcia-Murillas et al Science Trans Med 2015). We conducted an independent, prospective, multi-centre validation study.

Methods. In this validation study, a cohort of 170 early stage breast cancer patients were recruited from five hospitals into two prospective sample collection studies. Patients were scheduled to receive standard chemotherapy, surgery +/- radiotherapy, adjuvant endocrine therapy and HER2 antibodies as appropriate. Plasma samples were collected for ctDNA analysis at baseline, post-surgery, three monthly for the first year of follow-up, and six monthly thereafter and shipped to a central lab for processing. Using previously established criteria, tumor was sequenced to identify somatic mutations that were tracked by digital PCR in DNA extracted from 4mls of plasma at all available time points. Buffy coat DNA was analysed at all time-points to control for clonal haematopoesis of indeterminate potential (CHIP) detection. The primary endpoint was to compare invasive disease free survival between patients with and without detection of ctDNA after treatment. A combined analysis of this validation study, and the prior proof-of-principle study, was also conducted to analyse secondary endpoints.

Results. After tumor sequencing, 101 patients from the validation study had at least one mutation to track. At median 35.5 months follow-up, ctDNA was detected in plasma of 15.8% (16/101) patients. Detection of ctDNA strongly predicted relapse, hazard ratio 24.5 (95% CI 6.5 to 93.2, P<0.001 time-dependent Cox model), and was predictive of relapse in all tumor subtypes. In the combined analysis (N=144), lead-time between ctDNA detection and relapse was 10.7 months (95% CI 7.7-17.0). Six patients had a clinical relapse that was not detected by ctDNA prior to relapse. These patients had a distinct pattern of oligo-metastatic relapse, 3 patients with brain-only metastases (P=0.0068), 1 ovarian oligo-metastasis and 2 local disease recurrence. The level of ctDNA in baseline plasma, prior to treatment, was associated with tumor subtype, highest in triple negative breast cancer (P=0.0036).

Conclusion. Detection of ctDNA after treatment is associated with a high risk of future relapse in early-stage breast cancer. Prospective studies are required to assess the potential of molecular residual disease detection to guide adjuvant therapy.
Early detection of residual breast cancer through a robust, scalable and personalized analysis of circulating tumour DNA (ctDNA) antedates overt metastatic recurrence

Raoul C Coombes, Anne Armstrong, Samreen Ahmed, Karen Page, Robert K Hastings, Raheleh Salari, Himanshu Sethi, Anna-Rita Boydell, Svetlana V Shchegrova, Daniel Fernandez-Garcia, Kelly LT Gleason, Kate Goddard, Dave S Guttery, Zoe J Assaf, Mustafa Balcioglu, David A Moore, Lindsay Primrose, Samantha L Navarro, Alexey Aleshin, Farah Rehman, Bradley J Toghill, Maggie C Louie, Bernhard G Zimmermann, Cheng-Ho Jimmy Lin and Jacqueline A Shaw. 1Imperial College London, London, United Kingdom; 2Leicester Infirmary, Leicester, United Kingdom; 3The Christie Foundation NHS Trust, Manchester, United Kingdom; 4Natera, San Carlos, CA and 5University of Leicester, Leicester, United Kingdom.

Background: Many breast cancer patients relapse after primary treatment but there are no reliable tests to detect distant metastases before they become overt. Here we show earlier identification of recurring patients through a scalable personalised ctDNA analysis. The method is applicable to all patients, and not limited to hot-spot mutations typically detected by gene panels.

Methods: Forty-nine non-metastatic breast cancer patients were recruited following surgery and adjuvant therapy. Plasma samples (n=208) were serially collected semi-annually. Using the analytically validated Signatera™ workflow, we determined mutational signatures from primary tumour whole exome data and designed personalised assays targeting 16 variants with high sensitivity by ultra-deep sequencing (average >100,000X). The patient-specific assay was used to detect the presence of the mutational signature in the plasma.

Results: In 16 of 18 (89%) clinically-relapsing patients, ctDNA was detected ahead of metastatic relapse being diagnosed by clinical examination, radiological and biochemical (CA15-3) measurements, and remained ctDNA-positive through follow-up. Of the 2 patients not detected by ctDNA, one had a small local recurrence only (now resected) and the other had three primary tumours. None of the 31 non-relapsing patients were ctDNA-positive at any time point (n=142). Metastatic relapse was predicted by Signatera with high accuracy and a lead time of up to 2 years (median=9.5 months).

Conclusions: The use of a scalable patient-specific ctDNA-based validated workflow detects breast cancer recurrence ahead of clinical detection. Accurate and earlier prediction by ctDNA analysis could provide a means of monitoring breast cancer patients in need of second-line salvage adjuvant therapy in order to prevent overt life-threatening metastatic progression.
ESR1 mutation in cell free DNA (cfDNA) is associated with significantly increased circulating tumor cell (CTC)-clusters and progress in stage III/IV breast cancer after systemic treatments

Qiang Zhang¹, Lorenzo Gerratana¹, Youbin Zhang¹, Lisa Flaum¹, Ami Shah¹, Andrew Davis¹, Amir Behdad¹, William Gradishar¹, Leonidas Platanias¹ and Massimo Cristofanilli¹. Lurie Cancer Center, Northwestern University, Chicago, IL.

Introduction: CTCs play a critical role in the process of tumor metastasis, and a portion of CTCs may form clusters that contain two or more CTCs bound together which were reported to have up to 50-fold of potential of forming distant metastasis in breast cancer (MBC) as compared to individual CTCs. However, molecular and genomic characterization of CTCs cluster remain largely unknown. Here we report a highly significant correlation between ESR1 mutation in cfDNA, CTCs count and CTC-cluster, which may help to understand MBC metastasis and predict treatment benefit, especially for metastatic or recurrent disease.

Methods: A total of 80 whole blood samples (7.5ml/each) were collected from 80 patients with stage III/IV BCa after informed consent under IRB-approved trial at the RHLCCC at Northwestern University before and after systemic therapies. Among these 80 patients, 41 patients received chemotherapy and 23 patients received endocrine therapy, among which 20 patients received combo treatments (16 plus Palpociclib, 1 plus Ribociclib, 2 plus Everolimus, and 1 plus trastuzumab). CTC enrichment and enumeration were performed in CELLTRACKS ANALYZERII® System (Menarini) by using CTC Kit. Meanwhile, we detected the ESR1 hotspot mutations (Y537S and D538G) in plasma cfDNA from all 80 patients by Droplet digital PCR (ddPCR) assay using the QX200 ddPCR System (Bio-Rad). cfDNA was isolated from 2 mL of plasma using the QIAamp Circulating Nucleic Acid Kit (Qiagen) and the MAF was analyzed using QuantaSoft software (Bio-Rad). Database of CTCs and ESR1 mutation was linked with clinical database. Kruskal-Wallis test was used for statistics.

Results: Of the 80 samples analyzed, there were 57 samples without ESR1 mutations (Group 1), and 23 samples that had ESR1 mutations (8 Y537S mutations and 15 D538G mutations, Group 2). CTC positive (≥5) were detected in 13/57 samples (Group 1) and 15/23 samples, and the average amounts of CTCs were 21.77 CTCs/each sample and 59.86 CTCs/each sample in Group 1 and Group 2 respectively. There was a significant association between ESR1 mutations and high level of CTCs (P=0.000088). More important, CTC-clusters were found in 3 samples in Group 1 (5.26%) and in 5 samples in Group 2 (21.74%) respectively. There was a significant correlation between ESR1 mutations and CTC-clusters (P=0.026). Furthermore, there were 18/57 patients in group 1 and 5/23 in group 2 receiving chemotherapy. Moreover, 26/57 in group 1 and 15/23 in group 2 that received chemotherapy. Our results also confirmed that both endocrine therapy and chemotherapy benefited more patients without ESR1 mutations in compared with patients with ESR1 mutations (P<0.05).

Conclusion: We first elucidated the association between ESR1 mutations in ctDNA and CTC-cluster in MBC patients, and provides new insights on the molecular mechanisms associated with the metastasis process. In addition with the highly significant association between ctDNA ESR1 mutations and endocrine resistance we describe a new association allowing to expand the prognostic and predictive role of both tests enabling monitoring the metastatic prognosis and endocrine resistance for clinical decision-making.
Cell free DNA analysis identifies actionable \textit{ERBB2} amplifications in patients with HER2 equivocal breast cancer

Thereasa A Rich\textsuperscript{1}, Victoria M Raymond\textsuperscript{1}, Eugene R Ahn\textsuperscript{2}, Kimberly C Banks\textsuperscript{1}, Adam Brufsky\textsuperscript{3}, Christine Lee\textsuperscript{1}, Marc Lippman\textsuperscript{4}, Timothy J Pluard\textsuperscript{5}, Richard B Schwab\textsuperscript{6} and Richard B Lanman\textsuperscript{1}. \textsuperscript{1}Guardant Health, Redwood City, CA; \textsuperscript{2}Cancer Treatment Centers of America, Chicago; \textsuperscript{3}University of Pittsburgh Medical Center - Magee-Women's Hospital, Pittsburgh; \textsuperscript{4}University of Miami Miller School of Medicine, Miami; \textsuperscript{5}St. Luke's Cancer Institute, Kansas City and \textsuperscript{6}University of California San Diego Moores Cancer Center, La Jolla.

\textbf{Background:} Determination of \textit{ERBB2} (HER2) expression or amplification informs eligibility of HER2-targeted therapies. ASCO and NCCN guidelines recommend evaluation of HER2 status on primary invasive breast cancers and on a metastatic site if stage IV, where possible, as treatment is based on the status of the metastasis. Reassessment of HER2 status should also be considered in patients with disease recurrence as initially HER2-negative tumors may acquire HER2 amplification at progression. HER2 status can be complicated by equivocal results from \textit{in situ} hybridization (ISH) and/or immunohistochemistry (IHC). Clarification requires reflex testing on the same tissue specimen or repeat testing on a new specimen, however some patients’ tissue status remains equivocal. Furthermore, metastases to bone, lung, or brain may be difficult to re-biopsy or of low DNA quality. Rapid and non-invasive blood-based cell-free DNA (cfDNA) NGS may facilitate identification of HER2 targetable disease in advanced breast cancer.

\textbf{Methods:} We assessed the frequency of \textit{ERBB2} amplification detectable by a blood-based cell-free DNA (cfDNA) assay among patients with metastatic breast cancer with equivocal HER2 results in tissue. cfDNA samples were ordered as part of routine clinical care using an assay validated for the detection of copy number amplification in \textit{ERBB2} (tests run between 03/2014-04/2017 by Guardant Health, Redwood City, CA). Submitted pathology reports were reviewed for HER2 status which was categorized as positive, negative, or equivocal based on the interpretation issued by the reading pathologist at the time the test was ordered. Patients were included if they had an equivocal result on IHC and/or ISH unless both assays were performed on the same specimen and one provided a definitive negative or positive HER2 result. Additionally, 4 patients with equivocal IHC or ISH results were excluded as biopsy of another tumor site revealed a positive HER2 result around the same time as the equivocal test. For the 349 patients with multiple cfDNA samples, the earliest pathology report was referenced.

\textbf{Results:} Tissue HER2 status was available for 1,853 unique patients (98.8\% female, median age at testing was 58y, range 26-91y). 141 patients (7.6\%) had equivocal HER2 results in tissue; 99 by IHC alone, 14 by ISH alone, and 28 were equivocal by both assays. Among these, 126 patients (89.4\%) had at least one sample with ctDNA detected. 12/126 (9.5\%) had amplification of \textit{ERBB2} detected in at least one cfDNA sample. Samples were drawn a median of 267 days after tissue collection (range 4 days – 11.5 years). Frequency of \textit{ERBB2} amplification was similar regardless of time between tissue and blood collection but was higher among patients with ISH results alone (4/14, 36.4\%) compared to those with IHC alone (6/89, 6.7\%) or both assays (6/26, 7.6\%; \textit{p}=0.006).

\textbf{Conclusion:} cfDNA testing identifies a significant number of patients with HER2-targetable advanced breast cancer whose tissue was HER2 equivocal. cfDNA testing may supplement tissue-based methods to help clarify HER2 status in metastatic disease as well as identify patients who may acquire HER2 amplification subsequent to their initial biopsy.
Comparison of tumor genotyping and cell-free circulating tumor DNA sequencing in metastatic breast cancer patients and their utility in the selection of matched therapy

Neelima Vidula¹, Dejan Juric¹, Andrzej Niemierko¹, Laura Spring¹, Beverly Moy¹, Giuliana Malvarosa¹, Megan Yuen¹, Karleen Habin¹, Jennifer Shin¹, Jeffrey Peppercorn¹, Steven Isakoff¹, Leif Ellisen¹, A John Iafrate¹ and Aditya Bardia¹. ¹Massachusetts General Hospital, Boston, MA.

Background: Oncogenic mutations are potential targets for therapeutic intervention in metastatic breast cancer (MBC). While tumor genotyping (TG) has been viewed as the gold standard for identifying oncogenic mutations, cell-free circulating tumor DNA (cfDNA) is emerging as an alternate technique. We previously reported the selection of matched therapy targeted to an actionable mutation based on either TG or cfDNA testing (Vidula N, ASCO, 2018). Therefore, we are now comparing TG and cfDNA results in MBC patients undergoing both tests to examine their relative utility in the selection of matched therapy.

Methods: Patients with MBC at an academic institution who underwent both TG (Next Generation Sequencing/NGS, institutional platform, 104 gene assay) and cfDNA testing (NGS/Guardant360, 73 gene assay) between 1/2016-10/2017 were identified. A chart review was conducted to identify tumor subtype, demographics, treatment, TG and cfDNA results, and clinical outcomes. The relative utility of these tests in the selection of matched therapy was determined, and linked with clinical outcomes (progression-free survival and overall survival).

Results: Thirty patients who underwent both TG and cfDNA testing were identified. The median age was 60 years, the majority (97%) had hormone receptor (HR) positive/HER2 negative disease, and most patients had recurrent disease (83.3%) at MBC diagnosis. The median number of therapies prior to obtaining either test was 1 (cfDNA range 0-9, TG range 0-8). The majority had simultaneous cfDNA and tumor genotyping testing (83.3%) versus sequential testing (16.7%). Twenty-four (80%) patients had actionable mutations detected by cfDNA compared to 19 (63.3%) patients with actionable mutations detected by TG. The median number of actionable mutations detected by cfDNA was 2 (range 0-11) compared with a median of 1 (range 0-4) detected by TG. Failure of TG occurred in 2 of 30 patients (6.7%) but no test failures were seen with cfDNA. Eleven of 30 patients (36.7%) had ≥ 1 concordant mutation via cfDNA and TG. Altogether, 12 out of 30 (40%) patients received matched therapy, 5 of which were based on cfDNA actionable mutations alone (ESR1, ERBB2, CCND1, and PIK3CA), and 7 based on cfDNA and TG results (ESR1, PIK3CA, STK11, and BRCA). Twelve of 24 (50%) patients with actionable cfDNA mutations went on to receive matched therapy compared with 7 of 19 (36.8%) patients with actionable TG results. Matched therapies included SERDs, inhibitors of CDK 4/6, PI3K, mTOR, HER2 directed therapy, and DNA damaging chemotherapy. The impact of matched therapy on survival outcomes will be presented at the meeting.

Conclusions: In patients undergoing both TG and cfDNA testing, both tests identify a significant cohort of HR+ MBC patients with actionable mutations, with greater detection of actionable mutations by cfDNA. Greater application of matched therapy occurred via cfDNA, which independently informed the selection of matched therapies. Further research is needed to prospectively evaluate the clinical utility of blood based genotyping assays versus TG for patients with MBC.
A comprehensive liquid biopsy in patients undergoing neoadjuvant therapy

Ana C Sandoval Leon¹, Kelsie Medina Saenz¹, Philip Miller², Adam Benson², Carmen Calfa¹, Reshma Mahtani¹, Joyce Slingerland¹, Alejandra Perez¹, Charles Vogel¹, Frances Valdes-Albini¹, Dorraya El-Ashry³ and Marc Lippman¹. ¹University of Miami, Miami, Fl; ²Foundation Medicine, Inc, Cambridge, MA and ³University of Minnesota, Minneapolis, MN.

Background: Precision medicine is revolutionizing breast cancer (BC) care. Comprehensive liquid biopsies are a tool for personalized care in patients with locally advanced breast cancer (LABC). Identifying robust biomarkers as part of a comprehensive liquid biopsy to predict response to treatment is of immense clinical interest.

Methods: After obtaining IRB approval, serial blood samples were collected from patients with LABC undergoing neoadjuvant therapy. Paired biopsies were collected prior to treatment and were sent to Foundation Medicine for next-generation sequencing (NGS). We used a sized-base microfilter technology to capture circulating tumor cells (CTCs) and circulating cancer associated fibroblasts (cCAFs). Patients with one or more CTCs or cCAFs were deemed positive for these tests. Additionally, in collaboration with Foundation Medicine, we extracted circulating tumor DNA (ctDNA) and we analyzed it using the FoundationACT platform. Patients with a detectable genomic alteration in their plasma were considered as having a positive ctDNA test. Our primary objective is to determine if a comprehensive liquid biopsy can serve as a prognostic marker of pathologic complete response (pCR).

Results: For this analysis we describe our findings in the initial blood draw of the first 18 patients enrolled. The mean age is 54 years (38-70). All patients who had their tumors sequenced had a detectable mutation. Consistent with the findings of others, we found TP53 mutations to be the most prevalent at 83.3%. We found that 44% of patients had ctDNA, 68.4% had cCAFs and 78.9% had CTCs. Many patients also had clusters of cells, consisting of one cell type, or co-clusters, consisting of both. 38.9% had CTC clusters, 16.7% had cCAF clusters and 16.7% had co-clusters (CTCs and cCAFs together). Some patients with CTCs did not have cCAFs and vice versa. The number of CTCs and cCAFS did not correlate with stage of disease or receptor status.

Conclusions: We describe a comprehensive liquid biopsy combining a sized-based microfilter technology for CTC and cCAFs identification and the FoundationACT platform for ctDNA analysis is feasible and these biomarkers can be detected in patients with LABC prior to the initiation of neoadjuvant therapy. Our study is accruing rapidly, and we will update our results with the longitudinal collection and the prognostic value of a comprehensive liquid biopsy at the time of the meeting.
Characterization of circulating tumor free DNA (ctDNA) obtained from patients with metastatic breast carcinoma (MBC) undergoing systemic therapies using comprehensive genomic profiling

Qiang Zhang¹, Lorenzo Gerratana¹, Youbin Zhang¹, Lisa Flaum¹, William Gradishar¹, Leonidas Platanias¹ and Massimo Cristofanilli¹. ¹Lurie Cancer Center, Northwestern University, Chicago, IL.

Introduction: Therapeutic benefit from individual treatments in patients with MBC is limited to small subsets of patients and of short duration due to tumor heterogeneity. Novel molecular diagnostics including ctDNA has been shown to predict response or resistance and survival. However, the frequency of detection of actionable mutations using ctDNA is variable based upon tumor related factors and diagnostic platform sensitivity (e.g. ddPCR or NGS). We evaluated a novel NGS technology in the ability of detecting driver and clonal genomic abnormalities in samples from MBC patients. Moreover, we wanted to compare the new technology to another state-of-the-art, commercially available diagnostic ctDNA testing with similar sensitivity to demonstrate both are able to detect genomic abnormalities in MBC.

Methods: This study included 30 samples from 15 patients with stage III/IV BCa treated at NMH (2016-2017) and who received standard systemic treatments based on disease subtypes longitudinally characterized for ctDNA before or 3 months after systemic therapies respectively. ctDNA from clinical plasma samples was first analyzed using PredicinePLUS, a NGS-based assay (Predicine Inc) with a 180-gene panel for genomic alterations mutations. The results were then independently analyzed with Guardant360™ (Guardant Health), a 73-gene panel. Matched pairs variations between Guardant360™ and Predicine was compared by Wilcoxon signed-ranks test. The prognostic impact of ctDNA was tested through Cox regression.

Results: Genomic Alterations (SNVs, Indels and copy number variations) were detected on 43 genes by PredicinePLUS assay. All samples (100%) demonstrated at least 1 somatic alterations. There were 75 mutations detected within 29 genes, and the variant frequency of mutated genes ranges from 0.11% to 68.56%. Median variant frequency was around 3.42%. Key cancer related genes including TP53, ESR1, PIK3CA, PTEN and BRCA1, are frequently mutated. Copy number variation were detected on 18 genes, among which 15 genes showed copy number gain, including MYC, PIK3CA, CCND1, and 3 genes (ATM, BRCA1 and CDKN2A) with copy number loss. There were no significant difference of %ctDNA (P=0.3967) and number of variations (P=0.5) between results of Predicine and Guardant360™, neither to the comparison of main detected alterations (BRCA1, ESR1, MYC, PIK3CA and TP53) with Guardant360™ and Predicine (P=1). Furthermore, results from Predicine indicated that there is correlation with treatment response and benefit. A significant decrease on variations in %ctDNA levels (P=0.028) and variations in the number of genomic variants (P=0.028) after systemic therapies, was associated with longer overall survival.

Conclusions: Our study describes a novel diagnostic platform with the ability to identify ctDNA mutation and copy number variations in patients with MBC receiving systemic therapy. We also confirm that when comparing ctDNA using NGS platforms with similar sensitivity, the results are robust and reproducible which indicates that these technologies can be reliably and routinely used as non-invasive method for monitoring response to systemic therapies and predict the prognosis in MBC.
Combined analysis of tissue and blood biopsies by NGS in patients with advanced breast cancer identifies targetable molecular alterations

Jose F Salvador¹, Joseph A Pinto¹, Jhahaira M Araujo¹, Indira Tirado-Hurtado¹, Claudio J Flores¹, Luis A Chirinos², María C Requena¹, Sonnia Carpio³, Ana Finzel Pérez³, Alfredo Aguilar¹, Fiona Demol³ and Luis J Schwarz¹.¹Oncosalud-AUNA, Lima, Peru; ²Universidad Científica del Sur, Lima, Peru and ³OncoDNA, Gosselies, Belgium.

Background: Targeted-next generation sequencing (t-NGS) analysis in tissue and peripheral blood is increasingly performed in patients with advanced cancer. Liquid biopsy is a non-invasive method that allows to understand the molecular changes occurring in the tumor in real-time, derived from intratumor heterogeneity and/or therapeutic pressure. In the present work we sought to elucidate the ability of liquid biopsy to detect mutations related with acquired resistance.

Methods: 190 formalin-fixed paraffin-embedded (FFPE) samples from primary and metastatic tumors of patients with advanced breast cancer (ABC) were analyzed by OncoDEEP® (1000X depth of coverage of 75 gene alterations including point mutations, insertions/deletions, gene fusions and copy number variations), and comparison between targeted-NGS results from matched primary/metastatic tumors (FFPE) and cell-free DNA (cfDNA) recovery from plasma analyzed by OncoSTRAT&GO® in 34 patients with ABC (193 genes with 1000x and 40 genes with 10000x depth coverage for FFPE and plasma, respectively).

Results: Of the 190 FFPEs analyzed by OncoDEEP®, 41% were triple negative breast cancer (TNBC), 49% hormone receptor positive (HR+) and 11% were HER2+. Mutations in TP53 (44.2%), PIK3CA (41.1%) and ERBB2 (9.47%) were the most frequent. As expected, PIK3CA and TP53 mutations were significantly higher in HR+ and TNBC tumors, respectively (PIK3CA: 53.8% for HR+ vs 28.6% and 30% for TNBC and HER2+, respectively; TP53 68.8% for TNBC vs 26.9 and 30% in HR+ and HER2+, respectively; in both cases p<0.001). Interestingly, the alteration c.1459-7C>T in JAK1 (unknown significance) was detected in 8% of patients (9.7% and 6.5% in HR+ and TNBC, respectively). Also, in contrast to other reports, high frequencies of APC alterations were found exclusively in HR+ tumors (previously reported as germline mutations). From the OncoSTRAT&GO® analysis (tumor tissue and cfDNA), ESR1 and FGFR mutations in HR+ ABC were significantly more present in cfDNA (9/20 mutations found [45%]) compared to tumor tissue analysis (18/93 mutations found [19.3%]) (p=0.02), and in three patients, mutations in ESR1 and FGRF were only detected in cfDNA. Finally, 11/34 cases (32.3%) showed gene mutations only in cfDNA with predominant alterations in MAPK signaling pathway (54.5%), TP53 (36.4%) and ESR1 (18.2%), the latest as previously described.

Conclusions: JAK1 and APC mutations need further evaluation to establish their clinical significance in ABC. The combination of tumor tissue and cfDNA t-NGS analyses into clinical routine enables detailed and comprehensive evaluation of tumor heterogeneity under therapeutic pressure; in our cohort, known mutations for acquired resistance to endocrine therapy (ESR1 and FGFR2) were better detected by cfDNA compared to tumor tissue (45% vs 19.3%) in HR+ ABC patients, increasing the probability to identify early drug resistance to prioritize patients’ selection into clinical trials with targeted agents.
The analysis of cell-free DNA and circulating tumor cells from one blood tube might empower treatment decisions in metastatic breast cancer patients

Sabine Kasimir-Bauer¹, Ann-Kathrin Bittner¹, Oliver Hoffmann¹, Siegfried Hauch², Markus Sprenger-Haussels², Markus Storbeck², Karim Benyaa², Peter Hahn², Pawel Mach¹, Mitra Tewes³ and Rainer Kimmig¹. ¹University Hospital, Essen, Germany; ²QIAGEN GmbH, Hilden, Germany and ³Dep. of Int. Med. (Cancer Res), Essen, Germany.

Background: The detection and characterization of circulating tumor cells (CTCs) as one of the analytes in liquid biopsy has been considered as surrogate marker to improve treatment decisions in metastatic breast cancer (MBC). In addition, cell-free tumor DNA (ctDNA) released by tumor cells and harboring tumor-associated variants is further discussed to give additional information for therapeutic options. Thus, CTC and ctDNA analysis from the same blood tube is desired. To test usability of plasma, generated after CTC isolation from whole blood for ctDNA analysis, we analyzed ctDNA from 42 hormone receptor-positive/HER2-negative MBC patients (pts) for the detection of tumor-associated variants (plasma isolated straight from whole blood) and compared the results for similarities and differences of the detected variants in a subgroup of these pts to those, obtained from plasma generated after CTC selection (taken from a separate tube).

Methods: 4 ml plasma of all MBC pts and 4 ml plasma obtained after immunomagnetic isolation of CTCs from 2x5ml blood [AdnaTest EMT-2/Stem Cell Select (n=17pts) followed by multimarker qPCR] were used for the analysis of cell-free DNA (cfDNA) applying the QIAamp MinElute ccfDNA Kit. A total of 30ng - 60ng cfDNA was applied for library construction using the QIAseq Targeted DNA Panel for Illumina with integrated unique molecular identifiers. Sequencing was executed on the NextSeq® 500 platform (Illumina, US). Data were analyzed using the QIAseq Targeted Sequencing Data Analysis Portal, the Biomedical Genomics Workbench and the Ingenuity Variant Analysis. All materials used were manufactured by QIAGEN, Germany.

Results: In the total cohort of 42 pts, most variants of all analyzed genes were detected in the MUC16 gene (31.2%). ERBB2, EGFR and AR (androgen receptor) also showed high numbers of variants (11.6%, 11.0% and 8.9%, respectively) with a majority detected pathogenic variants (47.7%) in AR. 92% of all detected variants showed an allele frequency of <5% and some of the detected MUC16, ERBB2 and AR mutations significantly correlated with overall survival. Comparing the plasma results from a separate blood draw with the results from plasma samples after CTC selection in a subgroup of 17/42 pts, no significant difference was found for cfDNA concentration but variability within the cohort. Whereas the variant comparison of ctDNA isolated from both plasma sources showed great concordance, additional variants (around 15%) were exclusively found in one of the two matched samples. Interestingly, in the variant population exclusively found in ctDNA isolated after CTC isolation, the relative amount of pathogenic variants was increased compared to the variant fraction only found in ctDNA from plasma of a separate blood tube. Results obtained for frequently overexpressed CTC transcripts in this subgroup included genes involved in the PI3K signaling pathway as well as ERBB2 and ERBB3 in about 30% of the pts.

Conclusion: We here present a feasible workflow for CTC and ctDNA evaluation for expression and mutation analysis from the same blood sample. These data emphasize that the use of different liquid biopsy analytes can empower treatment decisions of MBC pts in the future.
Genomic alterations of cell-free DNA in early breast cancer patients with recurrence

Jisun Kim1, Whi Kyung Jo1, Kyung Yeon Kim2, Byung Joo Kim2, Sae Byul Lee1, Hee Jin Lee1, Jong Han Yu2, Hee Jeong Kim1, Il Young Chung1, Beom Seok Ko1, Sung-Bae Kim1, Kyung Hae Jung1, Jin Hee Ahn1, Suwhan Chang4, Jong Won Lee1, Byung Ho Son1 and Sei Hyun Ahn1. 1Asan Medical Center, Seoul, Republic of Korea; 2Macrogen Inc, Seoul, Republic of Korea; 3Samsung Medical Center, Seoul, Republic of Korea and 4Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.

Cell-free DNA (cfDNA), as a non-invasive strategy, provides substantial benefit to overcome tumor heterogeneity. Surveillance of recurrence after standard treatment in early breast cancer (BC) using cfDNA, enables to detect minimal residual disease (MRD), also to identify genomic alterations driving recurrences. We aimed to assess the role of cfDNA in detecting MRD by investigating genomic alterations of 1) primary, recurred tumor and 2) cfDNA at time of recurrence using deep targeted sequencing. Fifty-four early BC patients were enrolled prospectively between 2014 and 2017 at time of recurrence. Median disease free interval was 28.5 months (range 6.2-49.8). 62.7% (32/51) were hormone receptor (HR) positive (28 HRpos/HER2neg, 4 HRpos/HER2pos), 11.8% (6/51) were HRneg/HER2pos and 25.5% (13/51) were triple negative BCs. 59.3% (32/54) patients developed loco-regional recurrence (15 local recurrence only, 13 regional only, 4 with both) and distant metastasis was observed among 40.7% (22/54) patients. Cell-free DNA was extracted from 5cc blood at time of recurrence. Deep targeted sequencing was performed using customized NGS panel – encompassing 426 cancer-related target coding region, 242 fusion and amplification-related region- of cfDNA and FFPE (formalin fixed paraffin embedded) tumor samples archived from surgical resection or biopsy. Deep targeted sequencing data was successfully performed in 72.1% (31/43) plasma samples and sequencing yield was significantly lower when stored for more than 2yrs (46.2% vs 83.3%).

Mutations of cfDNA and tumor (primary, recurred) were analyzed. Mean sequencing depth of cfDNA and FFPE were x425.7 and x777.6 respectively. Median number of pathogenic mutations found in primary tumor, cfDNA and recurred tumor were 27(range 12-99), 25(range 8-85) and 9(range 0-23). Among mutations found in primary tumor, 27.4% were shared mutations (range 8.1%-72.7%) with recurred tumor and 26.1% were shared mutations (range 4.7%-69.2%) observed in cfDNA sample. Among mutations found in recurred tumor, 40.9% were observed in cfDNA (range 17.7-87.5%). In primary tumor, median number of mutations with allelic fraction (MAF)>10% were 12 (range 4-21) and at least one mutation was found in cfDNA at time of recurrence. Among mutations with MAF>10%, 59.4% and 69.1% were found in cfDNA and recurred tumor. Known oncogenic mutations of PIK3CA, TP53, GATA3, AKT1, ESR1, RELN, ERBB2, ERBB3, BRCA1 mutation were found. PIK3CA gene (p.H1047R) was found in two cases both in primary tumor and cfDNA at recurrence (MAF 11.4% vs 5.3% and 12.3% vs 15.4%) suggesting de novo driver mutation. One patient developed regional recurrence during adjuvant aromatase inhibitor with ESR1 V392I mutation in both cfDNA and recurred tumor (MAF 48.1 and 54.5%), while another patient's recurred tumor during aromatase inhibitor harbored ESR1 D538G mutation exclusively in recurred tumor with MAF <1%. Both patients had no ESR1 hotpot mutation in primary tumor.

Our data showed sequencing yield of 83.3% in plasma samples within 2yr. Pathogenic mutations in primary tumor, especially when MAF>10%, half of them was observed in cfDNA at time of recurrence. ESR1 mutation should be included in cfDNA surveillance for patients undergoing endocrine therapy even absent in primary tumor.
Low peripheral blood CD4/CD8 ratio at the time of surgery is a negative long-term prognostic factor in women with early stage breast cancer

Mark Jesus M Magbanua¹, Christina Yau¹, Janet H Scott¹, Laura van't Veer¹, John W Park¹, Laura Esserman¹ and Michael Campbell¹. ¹University of California San Francisco, San Francisco.

It is hypothesized that cancer prognosis may be related to the functional status of the immune system. We examined the correlation between peripheral blood CD4/CD8 ratio measured at the time of surgery and clinical outcome in patients diagnosed with early stage breast cancer.

Patient and Methods
Peripheral blood from 57 treatment-naïve early breast cancer patients, not eligible for neoadjuvant chemotherapy, was collected on the day of definitive surgery. CD4+ and CD8+ T cells were enumerated using flow cytometry and the ratio between the two immune cell populations was calculated. Cox regression analyses were performed to determine the relationship between CD4/CD8 ratio vs. distant disease-free survival (DRFS), breast cancer-specific survival (BCSS) and overall survival (OS). The median follow-up times were 10.1 years (range: 0.4-17.5) and 15.0 (range: 1.0-18.5) for DRFS and BCSS/OS, respectively.

Results
The patients’ mean age at diagnosis was 54 years old (range: 31-78). 82% were hormone receptor-positive, 21% HER2-positive, and 61% node-negative. The median CD4/CD8 ratio was 2; and a ratio ≤ 2 was considered low. CD4/CD8 ratio was not associated with any of the clinicopathologic variable examined. Multivariate analysis using a survival model that adjusted for potential confounding factors (age, tumor size, grade, stage, hormone receptor, HER2, lymph-node status) revealed that patients with low CD4/CD8 ratio have statistically significant increased risk of distant recurrence (DRFS HR 5.3, Wald p=0.0381) and death (OS HR 3.8 Wald p=0.0271).

Conclusions
Immune dysfunction at the time surgery is correlated with long-term increased risk for metastatic recurrence and death. Larger clinical studies are warranted to confirm the results of this study.
Molecular characterization of circulating tumor DNA in Chinese metastatic breast cancer (mBC) patients

Jianjun Yu⁴, Huiping Li¹, Simon Zhang⁵, Amy Wang⁵, Zhixin Zhao⁵ and Xiao-Ran Liu¹. ¹Peking University Cancer Hospital and Institute, Beijing, China and ²Huidu Shanghai Medical Sciences Ltd., Shanghai, China.

Background: Circulating tumor DNA (ctDNA) have been increasingly used as a minimal invasive test to detect genomic alterations of cancer patients.

Methods: We performed a retrospective analysis of blood samples from mBC patients (pts) collected at baseline, on-treatment, and disease progression. A highly sensitive, plasma-derived ctDNA-based NGS assay (PredicinePLUS, a comprehensive 180 key cancer gene panel) was used to detect somatic mutations and copy number variations in ctDNA with an in-house propriety algorithm.

Results: In this study, we evaluated 162 blood samples from 109 mBC pts who underwent systematic therapy at Beijing Cancer Hospital with approval from Research Ethics Committee. 129 samples from 92 pts passed NGS quality check, and were included in the analysis. Among these pts, the percent of HR+, HER2+ and Triple-Negative pts is 36.8%, 29.5% and 31.5%, respectively. About 86% samples contain somatic mutations and/or copy number variations. Collectively, 372 somatic mutations (SNV and Indels) were detected on 76 genes, among which TP53 (44.2%), PIK3CA (25.3%), BRCA2 (10.5%) and ATM (10.5%) were frequently altered with frequency varying across different subtypes. ESR1 hotspot mutations ((D538G and Y537S/N/C) were also detected in a subset of HR+ patients. Copy number gain or loss was detected on 32 genes, including amplification of ERBB2, PIK3CA, FGFR1 and deletion of CDKN2A, ATM, RB1 etc. Importantly, ERBB2 copy number amplifications were only detected in HER2 IHC positive cases for base-line samples, leading to 68% sensitivity and 100% specificity. Interestingly, ctDNA yield increased as disease progressed, suggesting ctDNA yield may serve as a potential biomarker for predicting treatment response and monitoring disease progression. Additional genomic alterations that change dynamically along with the course of treatment or associate with drug response and/or resistance were also identified.

Conclusions: This study demonstrated ctDNA-based genomic analysis was highly sensitive and specific in detecting various genomic alterations, consistent with other published studies. It also suggests that HER2 copy number amplification could be robustly assessed in a non-invasive manner.
Association between interleukin 2 (IL-2) and circulating tumor DNA (ctDNA) is a novel biomarker for patients with metastatic breast cancer (BCa) after systemic therapies

Qiang Zhang¹, Lorenzo Gerratana¹, Youbin Zhang¹, Lisa Flaum¹, Ami Shah¹, Andrew Davis¹, Amir Behdad¹, William Gradishar¹, Leonidas Platanias¹ and Massimo Cristofanilli¹. ¹Lurie Cancer Center, Northwestern University, Chicago, IL.

Introduction: The detection and monitoring of ctDNA in metastatic breast cancer showed ability to predict treatment resistance and outcome. But the mechanisms has been a challenge to clinicians. Immune escape and immune tolerance has also been reported to cause BCa progress. Herein, we report a novel finding of the association between plasma IL-2 and the ctDNA in advanced BCa patients who received the systemic therapies, and it is potential utilization in clinic.

Methods: This study enrolled 43 patients with stage III/IV BCa at the Northwestern Memorial Hospital (2016-2017) that had longitudinally detection of ctDNA and circulating tumor cells (CTCs) before (baseline, BL) or 3 months after (first evaluation, FE) systemic therapies respectively. Duplicate whole blood samples (7.5ml/each) were collected in EDTA tubes from these patients. Plasma ctDNA was analyzed using the Guardant360 NGS-based assay (Guardant Health) and CTC enrichment and enumeration were performed in FDA approved semi-automated fluorescence CELLTRACKS ANALYZERII® System (Menarini Silicon Biosystems) by using CELLSEARCH® CXC Kit (Menarini). ELISA (Fisher) for IL-2 was performed by using patients' plasma.

Results: CTCs ≥ 5 were found in 23 patients at BL and 21 patients in FE respectively. There were 12 patients that had increase CTCs, and 31 patients with similar or less CTCs FE after systemic therapies. Decreased in CTCs was associated with increased IL-2 (P=0.004). The FE analysis showed that IL-2 dropped significantly in patients with CTC stably ≥5 (from 95.84pg to 79.46pg) after therapies (P<0.001). Furthermore, baseline IL-2 levels were significantly higher in patients with %ctDNA levels ≥5.7 (97.15pg) compared to patients with %ctDNA levels <5.7 (68.64pg) (P=0.0027). No other associations were highlighted in respect to age or number of ctDNA alterations. There was no significant variations between BL and FE levels of IL2 were observed according to BCa subtypes nor in respect to baseline %ctDNA ≥5.7 or CTCs ≥5. Compared with low level of BL IL-2 (<78.3pg) group, high level of BL IL-2 (≥78.3pg) had a significant negative impact on overall survival (OS) (P=0.037) in univariate analysis.

Conclusions: Our findings indicated that aggressive BCa with high level ctDNA mutation are associated with high level of IL-2 and immune response in patients with advanced disease. In addition we confirm a reverse correlation between change of IL-2 and change of CTCs potentially indication of immune escape. In summary, the study shows a dynamic relation between IL-2 level and tumor burden (ctDNA) and immune escape (CTCs) suggesting another potential biomarker to monitor interaction between tumor and immune environment.
The prevalence of estrogen receptor-1 mutation in advanced breast cancer: The estrogen receptor one study (EROS)

Omar Najim$, Manon Huizing$ and Wiebren Tjalma$. 1University Hospital of Antwerp/ Multidisciplinary Breast Clinic, Edegem, Antwerp, Belgium; 2Faculty of Medicine/ University of Antwerp, Edegem, Antwerp, Belgium and 3University Hospital of Antwerp/ Biobank-department of Pathology, Edegem, Antwerp, Belgium.

Background
Estrogen receptor alpha (ESRα), encoded by the estrogen receptor-1 (ESR1) gene, is expressed in approximately 70% of all breast cancers, and hormonal therapy represents a major treatment modality in ESRα-positive cancers. The most commonly used endocrine therapies inhibit ESR activity by either targeting the ESR protein itself or depriving the receptor of its ligand. Endocrine therapy has become the mainstay of prevention and treatment of ESR+ breast cancers in all stages of the disease. Furthermore, ESR status might be a strong predictor of response to endocrine therapy. About 20% of patients who present with early disease will develop resistance manifested as recurrences either during or after adjuvant endocrine treatments. While in metastatic breast cancer (MBC) patients, the resistance rate could be as high as 30%. Recent studies unveiled that these ESR1 mutations lead to constitutive activity of the ESR, meaning that the receptor is active in absence of its ligand estrogen conferring resistance against endocrine therapy.

Purpose: The goal of the present study is to determine the frequency rate of ESR1 mutations in hormone-sensitive advanced breast cancer by using digital droplet PCR (ddPCR) technique.

Materials and Methods
This retrospective study was conducted in the Multidisciplinary Breast Clinic of the Antwerp University Hospital. The seven most common ESR1 mutations (c.1138G>C (p. (E380Q)), c.1610A>G (p.(Y537C)), c.1613A>G (p.(p.D538G)), c.1607T>G (p.(L536R)), c.1387T>C (p.S463R)), c.16410A>C (p.(Y537S)), c.609T>A (p.(Y537N)) were assessed in available baseline plasma samples of women with hormone sensitive progressive breast cancer. Inclusion criteria for study participation were: female, age above 18 years, breast cancer, positive ESR expression, 5 years endocrine therapy of the primary disease, disease progression under endocrine therapy. ESR mutations were analyzed in cell-free DNA (cfDNA) by using ddPCR.

Results
In EROS study, ESR1 mutations were successfully examined in cfDNA from 21 patients with advanced breast cancer. In the current study, we reported positive ESR1 mutation in 19% of patients (4/21; 95% CI, 5%-42%). The test sensitivity was lower than the targeted value <0.1% in 29% of patients (6/21). No significant statistical difference in baseline clinical characteristics was observed in patients with wild-type and mutant ESR (p>0.05). All the patients had received AI with a variable period of good response. Adjuvant endocrine therapy for primary disease was Tamoxifen (TAM) for 57% of patients (12 of 21) of whom 8 patients had received aromatase inhibitor (AI) after two years, while 43% of patients (9 of 21) had received AI as first line adjuvant hormonal therapy. However, there was no sufficient number of samples to formally analyze the clinical impact of ESR mutation on the type of endocrine therapy.

Conclusion
ESR1 mutation analysis should be considered in hormone-sensitive MBC patients to improve the therapeutic strategies in controlling ESR signaling before the occurrence of wide spread disease metastasis.

Key words: Estrogen receptor, Mutation, breast cancer, hormonal therapy, and metastasis.
Detection of plasma tumor DNA (ptDNA) in patients with hormone receptor-positive HER2-negative (HR+HER2-) early breast cancer (EBC) in clinical remission

Mirat Shah1, Natasha Hunter1, Jennifer Ensminger1, Daniel Shinn1, Alex J Cole1, Hannah E Quinn2, Daniel L Edelstein2, Chenguang Wang1, Karen L Smith1, Andrea L Richardson3, Ashley Cimino-Mathews1, Antonio C Wolff1, Karen Cravero1, Ben H Park1 and Vered Stearns1. 1Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD; 2Sysmex Inostics, Baltimore, MD and 3Johns Hopkins Medicine, Baltimore, MD.

Background: Detection of ptDNA in patients with HR+HER2- EBC in clinical remission may impact recommendations for type and duration of adjuvant endocrine therapy. A sensitive technique to identify tumor mutations in plasma is BEAMing digital PCR. The frequency and timing of detectable mutations in plasma of patients in clinical remission from HR+HER2- EBC are unknown.

Methods: We screened a prospective institutional repository for patients that met inclusion criteria. Eligible patients must have been enrolled to the repository between 12/1/2008 (repository start) and 12/31/2016, had HR+HER2- EBC, received follow-up at Johns Hopkins with appointment scheduled between 3/1/2017 and 12/31/2017, completed curative surgery at least 6 months prior to this appointment, been recommended or initiated adjuvant endocrine therapy, and been in clinical remission. Appropriate patients were approached for a current blood sample during their follow-up appointment in 2017. Blood was analyzed using a BEAMing digital PCR platform (Sysmex Inostics OncoBEAM™) for AKT1, PIK3CA, and ESR1 mutations.

Results: We identified 67 eligible patients and collected blood from 60. Most patients had relatively low risk disease including 40 patients (67%) with stage I disease, and only 21 patients (35%) received chemotherapy. Patients were evenly divided between receiving tamoxifen or an aromatase inhibitor, and some patients switched from one to the other. The majority of patients (68%) had surgery between 1 and 5 years prior to the current blood draw. Detailed patient characteristics are provided in Table 1.

Two out of the 60 patients had detectable ptDNA, both with stage IIA disease. One patient had a mutation in the ESR1 ligand-binding domain P535H 9 months after surgery and while taking adjuvant tamoxifen for 7 months. Sanger sequencing of primary tumor tissue did not reveal this mutation. Another patient had a mutation in PIK3CA exon 9 E542K 9.5 years after surgery and after taking adjuvant tamoxifen for at least 7 years. Amplifying this locus in DNA from primary tumor tissue was unsuccessful; further analysis using droplet digital PCR (ddPCR) is planned.

Conclusions: Detection of ptDNA was feasible in a relatively low-risk group of patients with HR+HER2- EBC in clinical remission. Sampling a larger number of patients is needed to gain more understanding of the frequency and timing of detectable ptDNA. Next steps should also focus on determining the natural history of detectable ptDNA in patients with HR+HER2 EBC in clinical remission which may impact adjuvant treatment recommendations.

Aggressive subgroups of metastatic triple-negative breast cancer: Inflammatory breast cancer and young patients in the Dana-Farber cell-free DNA cohort

Jasneet Singh¹, Sarah Asad¹, William Nock¹, Yiqing Zhang¹, Elizabeth Adams¹, Adrienne Damicis¹, Heather A Parsons², Viktor A Adalsteinsson³, Eric P Winer², Nancy U Lin², Ann H Partridge², Beth Overmoyer² and Daniel G Stover¹. ¹Ohio State University Stefanie Spielman Comprehensive Breast Center, Columbus, OH; ²Dana-Farber Cancer Institute, Boston, MA and ³Broad Institute of MIT and Harvard, Boston, MA.

Background: Relative to other metastatic breast cancer subtypes, metastatic triple-negative breast cancer (mTNBC) has a shorter duration of response to therapy and worse overall survival. Within mTNBCs, there is a prevailing belief that inflammatory breast cancer and young women tend to have among the most aggressive phenotypes. We investigated clinical and cell-free DNA (cfDNA) characteristics of inflammatory-mTNBC and young-mTNBC. We hypothesized that inflammatory-mTNBC may have distinct clinical and cfDNA characteristics, offering potential novel biomarker and therapeutic strategies.

Methods: 164 patients from the Dana-Farber metastatic triple-negative cell-free DNA cohort (Stover DG, et al J Clin Oncol 2018) were included in this secondary analysis. Patients were stratified into three groups: 1) inflammatory breast cancer (‘IBC’); 2) non-IBC patients aged 45 years (yr) or younger at primary diagnosis (‘non-IBC young’); and 3) non-IBC patients over age 45 yr at diagnosis. For each subset population, we evaluated clinicopathologic characteristics, sites of metastasis, survival outcomes, and cfDNA ‘tumor fraction’ – the fraction of DNA in circulation derived from tumor. Those patients with adequate cfDNA tumor content for high confidence copy number calls (n=101) were included in an analysis of copy number alterations.

Results: Among 164 patients with metastatic TNBC, 13.4% (22/164) had IBC, 37.8% (62/164) were non-IBC young, and 48.8% (80/164) were non-IBC and over 45 yr. Race and primary receptor status were similar. IBC patients were diagnosed at a higher stage (Chi-square p=0.0009) while non-IBC young patients were significantly more likely to harbor a BRCA mutation (Chi-square p=0.03). Analysis of metastatic sites revealed that IBC patients had significantly greater frequency of ipsilateral and contralateral breast chest wall recurrences (p=0.04 and p=0.046, respectively) while non-IBC young patients had the most frequent lung metastases (p=0.002). There were no significant differences in frequency of bone, brain, or liver metastases. cfDNA analyses showed that cfDNA ‘tumor fraction’ was highest in non-IBC young patients (ANOVA p=0.03 for maximum tumor fraction). Median overall survival from metastatic diagnosis was 22.9 months. IBC and non-IBC young patients had a worse prognosis relative to non-IBC patients over 45 yr (hazard ratio IBC=1.97, 95% CI 1.09-3.57; HR non-IBC young=1.60 95% CI 1.07-2.41; log-rank p=0.023). By subgroup, median overall survival from metastatic diagnosis for IBC was 15.2 months, non-IBC young 21.2 months, and non-IBC over 45 yr 31.2 months. Analyses of genome-wide copy number alterations from cell-free DNA will be presented.

Conclusions: Among metastatic TNBCs, IBC patients and non-IBC young patients have a significantly worse overall survival compared with non-IBC patients over 45 yr of age. Young patients have more frequent lung metastases and higher ‘tumor fraction’ of cfDNA. Confirmation of the reported findings is limited due to cohort size and may reflect referral bias.
Correlation between circulating tumor DNA (ctDNA) alterations and circulating tumor cells (CTC) uncovers new mechanisms of metastasis for patients with metastatic breast carcinoma (MBC)

Andrew Davis¹, Qiang Zhang¹, Lorenzo Gerratana¹, Youbin Zhang¹, Lisa Flaim¹, Ami Shad¹, Amir Behdad¹, William Gradishar¹, Leonidas Platanias¹ and Massimo Cristofanilli¹. ¹Lurie Cancer Center, Northwestern University, Chicago, IL.

Introduction: Novel molecular diagnostics including CTCs and ctDNA have been proved to predict disease metastasis and survival. However, the frequency of detection of actionable mutations using CTCs and ctDNA is variable based upon tumor related factors and diagnostic platform sensitivity. Herein, we evaluated a novel NGS technology in the ability of detecting driver and clonal genomic abnormalities in samples from MBC patients, and compared ctDNA alterations with CTCs and CTC-cluster. This study demonstrated several novel correlation between some specific ctDNA alterations and CTCs or CTCs related biomarkers, which opened new insight on mechanisms of metastasis for MBC.

Methods: This study included 52 samples from 26 patients with stage III/IV BCa treated at NMH (2016-2017) and who received standard systemic treatments based on disease subtypes. Whole blood samples (7.5ml/each) were used for CTC enrichment and enumeration in FDA approved CELLTRACKS ANALYZERII® System (Menarini). ctDNA from clinical plasma samples was analyzed by using PredicinePLUS, a NGS-based assay (Predicine Inc) with a 180-gene panel for genomic alterations mutations. Results of CTCs and ctDNA alterations were linked to clinical database. Matched pairs variations between CTCs and ctDNA alterations was compared by Wilcoxon signed-ranks test and Kruskal-Wallis test.

Results: Genomic Alterations (SNVs, Indels and copy number variations) were detected on 52 genes by PredicinePLUS assay. All samples (100%) demonstrated at least 1 somatic alterations. There were 75 mutations detected within 29 genes, and the variant frequency of mutated genes ranges from 0.11% to 68.56%. Increased CTCs were highly significantly correlated with genomic alterations in the genes (wild type vs alterations) including GATA3 (8vs 37), ESR1 (2.5 vs 41.3), CDH1 (3.5 vs 50.5) and CCND1 (4 vs 120) (P<0.01). Decreased CTCs were correlated with alterations of CDKN2A (20.5 vs 0) (P=0.025). CTC-cluster appear associated predominantly with alterations of CDH1 (P=0.0018), CCND1 (P=0.008) and BRCA1 (P=0.04). Furthermore, in HER positive CTCs group, ERBB2 mutations caused increased CTCs in compared with ERBB2 wild type (0 vs 5), when CCND1, CDKN2A, GATA3 and TP53 alterations were associated with increase of HER2 negative CTCs.

Conclusions: By using the novel diagnostic platform with the ability to identify ctDNA mutation and copy number variation, this study demonstrated several novel genes alterations which were highly correlated with CTCs, CTC-cluster and HER2. Some genes (CCND1 and CDH1) got involved into the changes on both CTCs and CTC-cluster, when some genes (CCND1, CDKN2A, ESR1 and GATA3) were related with change of CTCs and HER2 expression. Correlation of CTCs and ctDNA can be reliably and routinely used as non-invasive method for monitoring disease metastasis and predict the prognosis in MBC in clinic.
Liquid biopsy and re-biopsy: Tracking mutational trajectories in HER2+ breast cancer patients undergoing T-DM1 treatment

Matteo Allegretti1, Elena Giordani1, Beatrice Casini1, Paolo Romania1, Simona Gasparro1, Michelangelo Russillo1, Enzo Gallo1, Simonetta Buglioni1, Edoardo Pescarmona1, Francesco Cognetti1, Gennaro Ciliberto1, Patrizio Giacomini1 and Alessandra Fabi1.

1IRCSS Regina Elena National Cancer Institute, Rome, Italy.

Background: The antibody-drug conjugate Trastuzumab emtansine (T-DM1, Kadcyla®) is standard of care in HER2+ breast cancer patients on clinical progression after Trastuzumab/Pertuzumab and taxanes. Despite considerable clinical benefits, most patients rapidly develop progressive disease due to adaptive resistance, the molecular bases of which remain largely unknown and/or controversial. Next generation sequencing (NGS) and digital PCR (dPCR) applied to serial biological samples obtained through liquid biopsy (LB) and re-biopsy (RB) offer a unique opportunity to intercept mutational trajectories and uncover molecular patterns linked to primary as well as adaptive resistance.

Materials and methods: Tumor tissues (n=14), either from primary or metastatic lesions, and plasma samples (n=99) were collected, upon informed consent, from 9 breast cancer patients undergoing T-DM1 administration. Tissue (tDNA) and circulating tumor DNA (ctDNA) were extracted by the QIAmp DNA FFPE and CNA kits (Qiagen), respectively, and analyzed by ultra-deep sequencing and dPCR (IonTorrent S5 and QuantStudio 3D, LifeTechnologies) with commercial 400-gene panel and custom-designed dPCR assays. Genomic data were correlated with clinical imaging (CT/PET).

Results: Six out 9 (66.7%) patients experienced progression within 1 year of treatment (mean 192±97 days), whereas the remaining 3 were stable at the last follow up (> 400 days). No correlation was found between outcome and HER2, ER or PR status in the latest available (prior to T-DM1) archival tissue, in which NGS revealed several pre-existing mutations, including some associated with resistance to ERBB2 blockade. LB analysis detected increases in both baseline and de novo occurring aberrations in 5/6 (83.4%) relapsing patients. As compared to clinical imaging, progression disease was anticipated by an average lead time of 1.9 months (range 0.7-2.8). Surprisingly, the sixth relapsing patient underwent rapid progression (3 months) in spite of decreased PIK3CA p.E545K in blood, further confirmed in the re-biopsy, thus suggesting heterogeneous response to T-DM1 across multiple cancer cell populations. However, a single administration of T-DM1 resulted in ultra-fast (within few weeks) clearance of ERBB2 p.L755S ctDNA, and stabilization of two distinct ‘bystander’ TP53 ctDNAs (p.R273H and p.S241T).

Conclusions: Non-invasive LB monitoring of a small cohort of T-DM1-treated patients provides proof of principle of intersecting mutational trajectories, anticipation and classification of resistance, as well as de novo appearance/clearance of resistance mutations. Thus, LB and RB may hint at disease evolution and successive lines of medical treatment. This work was supported by AIRC (Nuvenia Fellowship to MA, IG 19052 to PG), EU commission (grant #633937 – ULTRAPLACAD), and Regina Elena National Cancer Institute intramural funding.
Circulating tumor DNA as a predictive biomarker of response to palbociclib-fulvestrant in patients with estrogen receptor-positive, HER2-negative metastatic breast cancer

Lauren Darrigues1,2, Jean-Yves Piergà1,3, Alice Bernard1, Ivan Bièche2, Amanda Silveira1, Marc Michel5, Marie-Paul Sablin5, Paul Cottu5, Coraline Dubot5, Romain Geiss3, Francesco Ricci5, Charlotte Proudhon5 and François-Clément Bidard1,3. 1Laboratory of Circulating Tumor Biomarkers, Institut Curie, PSL Research University, SiRIC, Paris, France; 2Institut Curie, Paris, France and 3Institut Curie, PSL Research University, Paris, France.

Background:
Following the PALOMA-3 study results, the combination of palbociclib, a cdk4/6 inhibitor, with fulvestrant has become a standard therapy in women with estrogen receptor-positive (ER+) HER2-negative (HER2-) metastatic breast cancer (MBC) whose disease progressed under hormone therapy. Palbociclib increased the progression-free survival (PFS) in all patient subgroups, and no predictive biomarker of palbociclib efficacy has been validated so far. In that context, we evaluated whether early changes of circulating tumor DNA (ctDNA) levels are associated with the efficacy of palbociclib plus fulvestrant.

Methods:
After providing written informed consent, ER+ HER2- MBC patients were included in a prospective observational cohort (“ALCINA”, NCT02866149) prior to the initiation of palbociclib plus fulvestrant. Tumor response was assessed by a radiological evaluation (RECIST v1.1) every 3 months. Fresh plasma samples were collected at baseline, before the initiation of treatment, at day 15, at day 30 and at disease progression. For each patient, DNA from archived tumor tissue was subjected to targeted NGS to identify a driver mutation. In patients with identified driver mutation, circulating cell-free tumor DNA extracted from plasma was subjected to digital droplet PCR (ddPCR). Ratios of ctDNA levels (J15/baseline and J30/baseline) were correlated with prospectively registered patient characteristics and outcomes. For the current analysis, “responders” were defined as patients who experienced a PFS longer than 3 months.

Results:
61 MBC patients have been included and 26 were eligible for ctDNA mutation detection, after the characterization of single nucleotide variations in PIK3CA (N=21 patients), TP53 (N=3) and AKT (N=2). At baseline, 21 patients (81%) had detectable ctDNA levels, with a median level of ctDNA of 381 copies/ml of plasma; There was no significant correlation between ctDNA levels at baseline and PFS (p=0.06).

cDNA levels decreased under therapy, with 82% and 68% of patients displaying detectable levels of ctDNA at day 15 and day 30. Patients with undetectable ctDNA levels at day 15 and, principally, at 30 were more likely to experience a PFS > 3 month (HR=5.8, 95% IC=1.5-22.5, p=0.004).

We explored ctDNA level ratios (day 15/baseline and J30/baseline) and found that all patients whom ctDNA increases at day 30 (31%) will not respond to treatment. Moreover, among all patients, ctDNA detection at day 30 is correlated with shorter PFS [HR=2.63 IC95 (1.1 to 6.5)].

At time of tumor progression, all patients presented increased ctDNA levels.

In addition to tumor tissue sequencing, activating ESR1 mutations were found at baseline in 5 patients (19%).

Conclusion:
Our study suggests that the efficacy of palbociclib and fulvestrant may be monitored by serial analyses of ctDNA levels, before radiological evaluation and that early ctDNA levels and dynamics are prognostics factors for PFS. A large randomized trial, PADA-1 (NCT03079011), is currently testing the utility of real time resistant subclones detection in ctDNA from ER+ HER2- MBC treated with palbociclib and aromatase inhibitor.
Multiplexed targeted digital sequencing of circulating tumor DNA to detect minimal residual disease in early and locally advanced breast cancer

Bradon R McDonald¹, Tania Contente-Cuomo¹, Stephen-John Sammut³, Brenda Ernst², Ahuva Odenheimer-Bergman¹, Nieves Perdigones¹, Suet-Feung Chin³, Maria Farooq¹, Patricia A Cronin², Karen S Anderson², Heidi Kosiorek², Donald Northfelt², Ann McCullough², Bhavika Patel², Carlos Caldas³, Barbara Pockaj² and Muhammed Murtaza¹,². ¹Translational Genomics Research Institute, Phoenix, AZ; ²Mayo Clinic, Scottsdale, AZ and ³Cancer Research UK Cambridge Institute, Cambridge, United Kingdom.

Background:
Circulating tumor DNA (ctDNA) analysis holds potential for minimal residual disease (MRD) detection in early stage breast cancer. However, sensitivity for MRD is limited due to low ctDNA levels in early stage patients and limited blood volumes. Loss of input DNA during library preparation, limited multiplexing or low sensitivity of current molecular methods further limit accuracy. To address this gap, we have developed TARgeted DiGital Sequencing (TARDIS), a novel method for simultaneous analysis of multiple patient-specific mutations in plasma DNA.

Methods:
Using tumor exome sequencing, we identify and prioritize somatic founder mutations, design nested primers and evaluate them for multiplex performance. Using 5-10 ng input plasma DNA, we perform 1) targeted linear pre-amplification to improve downstream molecular conversion, 2) single-stranded adapter ligation to incorporate unique molecular identifiers (UMIs) and 3) targeted PCR to prepare sequencing-ready libraries. The resulting sequencing reads have fixed target-specific ends and variable ligation ends. We utilize fragment size and UMIs to group sequencing reads into read families. To ensure specificity, we require targeted mutations are supported by 2 or more read families.

Results:
To assess analytical performance, we targeted 8 mutations in cell-free DNA reference samples with 0.25%-2% mutation allele fractions (AFs). Precision across 7-16 replicates at each AF level agreed with expectations of Poisson distribution, demonstrating effective analysis of ~70% of input DNA. At 2%, 1%, 0.5% and 0.25% AFs, variant-level sensitivity was 96.4%, 96.4%, 91.1% and 65.8%, approaching the theoretical limit given input DNA. At 0.25% AF, 3-7 mutations were detected per sample, achieving 100% sample-level sensitivity. In 16 wild-type replicates, no targeted mutations were called (100% specificity). Averaging multiple mutations improved precision in sample-level AF estimates. Mean AFs from 8 mutations for the 2% sample were 2.34%-2.80% (5.8% CV).

In 6 patients with breast cancer treated with neoadjuvant therapy (NAT), we analyzed 8-18 patient-specific mutations (mean 11.8). Before treatment, ctDNA was detected in 5/6 patients at mean AFs of 0.02%-1.19% (mean 0.40%), supported by 2-10 mutations (mean 5.6). Of these 5 patients, 4 had residual disease after NAT and ctDNA was detected pre-operatively or during NAT in 3/4 patients. 1 patient achieved pathological Complete Response and ctDNA was undetectable after NAT.

Conclusions:
Preliminary results suggest TARDIS enables accurate MRD detection after neoadjuvant therapy in patients with early stage breast cancer. On-going work is expanding this analysis to include additional patients and investigate the clinical validity of peri-operative ctDNA monitoring.

A blood based diagnostic/prognostic for early stage breast cancer

Jennifer Sims-Mourtada¹, Kimberly M Arnold¹ and Adam Marsh². ¹Helen F Graham Cancer Center, Newark, DE and ²Genome Profiling LLC, Newark, DE.

**Purpose:** Although improvements in mammographic screening, including digital mammography and 3D tomosynthesis, have occurred in recent years, the positive predictive value (PPV) of mammography remains low. Screening mammography has an average PPV for biopsy of 32.6 % (range 22.2-54). Furthermore, for women with abnormally dense breasts, mammography may be hard to interpret or may provide a false negative. Here, we report a blood diagnostic for women with breast lesions that is capable of detecting and discriminating epigenetic biomarkers associated with either invasive or more benign disease. Our approach is based on the premise that circulating lymphocytes undergo epigenetic changes upon exposure to the tumor microenvironment and these changes can be followed to track tumor progression from a non-invasive to an invasive state. We hypothesized that DCIS samples with high risk for progression would maintain a predominant epigenetic signature that would match those observed in invasive disease, while those DCIS samples considered to have low risk or benign disease would resemble controls. To test the utility of these epigenetic biomarkers, we employed a novel diagnostic model which uses a combined machine learning approach integrated with the recombinatorial strategy of a genetic algorithm, to screen a large response space of thousands of CpG sites to identify a small set of CpG sites (< 20) with the highest combined predictive power.

**Methods:** Blood was obtained from women with histologically confirmed DCIS (n=14), or invasive ductal carcinoma (n=10) and women with no evidence of breast lesions on mammography (n=10). PBMCs were isolated using a modified Ficoll-Paque gradient, and DNA was extracted using standard commercial kits. Epigenetic profiling of DNA was performed using a highly sensitive and quantitative analytics platform, which utilizes methylation sensitive restriction endonucleases to detect changes in methylation of CpG sites from standard NGS data. Risk of invasiveness potential was determined based on pathologic criteria. Samples were scored as low risk (Cribriform subtype, no necrosis, low mitotic index) or high risk (Comedo or solid subtype, high mitotic index, necrosis).

**Results:** Non-metric multidimensional scaling ordination analysis of the CpG sites revealed highly distinct methylation patterns between Normal, DCIS and invasive samples. Using a Likelihood Ratio Test with defined ANOVA contrasts, over 14,000 significantly different methylated CpG sites were identified (p<0.05 after false discovery rate correction). A proprietary machine learning diagnostic model was employed to reduce this high-dimensional variable space to the most effective set of CpG sites. DCIS and invasive samples were discriminated in blinded tests (n=17) with 69% accuracy. Prognostic ability was determined in a blinded study of 10 DCIS samples in which we obtained an accuracy of 90% for risk assessment based on our pathological criteria.

**Conclusions:** Preliminary studies show strong ability of the identified DNA methylation metrics to detect and discriminate invasive and non-invasive breast lesions. The quantitative sensitivity and selectivity of this new diagnostic/prognostic blood test will be determined in larger patient cohorts.
Clinical significance of serum PSA in breast cancer patients

Toru Hanamura¹, Koichi Ohno¹, Shinya Houkibara¹, Hideki Murasawa¹, Toshitsugu Nakamura¹, Hidehiko Watanabe¹, Machiko Kaizuka², Shinji Sawano³, Hiroshi Koyama⁴ and Ken-ichi Ito⁵. ¹Japanese Red Cross Society Suwa Hospital, Suwa, Nagano, Japan; ²Suwa Central Hospital, Chino, Nagano, Japan; ³Okaya City Hospital, Okaya, Nagano, Japan; ⁴Koyama Clinic, Suwa, Nagano, Japan and ⁵Shinshu University School of Medicine, Matsumoto, Nagano, Japan.

Background: Recent preclinical data suggest that estrogen receptor (ER) positive breast cancer (BC), may switch from dependence on ER to androgen receptor (AR) as possible mechanism of resistance to ER-targeted endocrine therapy. AR dependency has also been suggested in a subset of ER-, AR+ BC. Based on these findings, clinical trials testing AR-targeting therapies in BC have been conducted. However, predictive markers for response to this type of therapies remain to be elucidated. PSA is the product of an androgen-responsive gene produced also in BC, and serum PSA (sPSA) could be detected in BC patients by a highly sensitive assay. Hypothesis: If sPSA reflects AR dependency of BC, it might be useful as a predictive marker for response to AR-targeting therapy. Methods: In this study, we investigated whether tumor-derived sPSA could be detected in BC patient, and if it might reflect tumor biology. In metastatic breast cancer (MBC) patients continuously observed, sPSA was evaluated monthly by CLEIA method (detection sensitivity ≥3 ng/L). Similarly, sPSA was evaluated at arbitrary points in non-BC control and point analysis BC group enrolled regardless of clinicopathological factor or treatment history. In the observational group, the relationship between change in disease condition and sPSA was analyzed. Next, correlations between sPSA and various clinicopathological factors were analyzed using combined data of point analysis group and initial sPSA value of observation group. In this study, 146 BC (26 observation group and 120 point analysis group) and 99 control were enrolled.

Results: In the observational analysis, 5 cases showed sPSA change well reflected the disease condition, but not in other 5 cases. In remaining 16 cases, sPSA was undetectable or the observation period was insufficient (<4m). In the point analysis, sPSA was detected in 28.3% and 28.1% in control and BC respectively. Although in pre-menopausal state, there was no significant difference in sPSA between control and BC (4.4 ± 6.98 ng/L vs 3.7 ± 5.5 ng/L), in post-menopausal state, sPSA was significantly higher in BC compared with control (0.7 ± 2.5 ng/L vs 64.6 ± 357.4 ng/L; P<0.05). In analysis limited to post-menopausal BC, sPSA was higher in MBC (de-novo stage 4 and recurrence) compared with non-MBC (Stage0-3) (106.0 ± 457.2 ng/L vs 2.1 ± 8.5 ng/L; P<0.05). Similarly, sPSA was higher in low ki-67 (<20%) cases compared with high ki-67 (≥20%) (105.7 ± 510.8 ng/L vs 30.5 ± 173.7 ng/L; p<0.05). There was no significant difference in sPSA due to histological type, ER or HER2 status and nuclear grade. In correlation analysis of quantitative data limited to post-menopausal MBC, sPSA was negatively correlated with Ki-67 (rS=-0.35, p<0.05) and positively correlated with treatment line of previous endocrine therapy (rS=0.27, p<0.05). It did not correlate with age, disease free interval, number of metastatic organs or treatment line of previous chemotherapy. Conclusion: Our data suggest that sPSA may be tumor-derived at least in post-menopausal MBC and may reflect some kind of tumor biological properties. These all findings justify further studies of the efficacy of sPSA as a predictive marker in AR-targeted therapy.
S100A11 is a diagnostic marker and promotes cancer progression for luminal breast cancer

Ava Kwong, Jue Wang, Jiawei Chen, Man T Siu, Isabella Chuek and Vivian Shin. 

1The University of Hong Kong, Pokfulam, Hong Kong; 2The Hong Kong Hereditary Breast Cancer Family Registry, Shau Kei Wan, Hong Kong and 3Hong Kong Sanatorium and Hospital, Happy Valley, Hong Kong.

Background: S100A11, also known as calgizzarin, is a member of S100 calcium-binding protein family and is upregulated in various cancers including lung cancer, renal cell cancer, ovarian cancer and pancreatic cancer. Many studies have shown that S100A11 is related to cancer progression. However, the function of S100A11 in breast cancer remains largely unknown. In the present study, we aim to investigate the underlying mechanism(s) of S100A11 in cancer cell proliferation, invasion, migration, and evaluate the clinical association with breast cancer.

Methods: The mRNA expression level of S100A11 in plasma samples from breast cancer patients and normal control individuals was detected with quantitative real-time PCR. Knockdown of S100A11 using small interfering RNA (siRNA) in luminal breast cancer cells (MCF-7 and T-47D) were used to study the biological function of S100A11 for the progression of breast cancer. Cell proliferation ability was analysed with MTT assay and colony formation assay. Cell invasion ability was analysed with transwell invasion assay. Cell migration ability was detected by wound healing assay. Cell cycle distribution and apoptosis were determined by flow cytometry.

Results: The mRNA expression level of S100A11 was significantly increased in the plasma samples obtained from 182 breast cancer patients compared with 115 normal control individuals, and the area under curve was 0.83. In particular, higher expression was associated with luminal breast cancer subtype as well as respective cell lines. S100A11 siRNA effectively inhibited the proliferation, invasion, and migration abilities of MCF-7 and T-47D cells. Knockdown of S100A11 caused cell cycle G1 arrest and induced apoptosis. Silencing of S100A11 decreased the mRNA and protein expression levels of cyclin D1 and NF-κB p50 whereas increased the expression level of E-cadherin in MCF-7 and T-47D cells.

Conclusion: These results suggest that S100A11 is upregulated in breast cancer and promoted cell proliferation, invasion and migration in MCF-7 and T-47D cells through the upregulation of NF-κB p50 and cyclin D1. Thus, S100A11 may be a potential diagnostic marker for luminal breast cancer subtype and also a therapeutic target for breast cancer.
Blood-based DNA methylation as epigenetic biomarkers for non-invasive detection of breast cancer

Dhruvajyoti Roy¹, Lianghong Zheng², Dan Liu², Gen Li², Mingzhen Li², Kang Zhang³ and Richard A Van Etten¹. ¹Laboratory for Advanced Medicine, Inc., Irvine, CA; ²Laboratory for Advanced Medicine, Inc., Beijing, China and ³Institute for Genomic Medicine, University of California at San Diego, La Jolla, CA.

**Background:** DNA methylation significantly contributes to all hallmarks of cancer. In particular, promoter hypermethylation has been identified as a potential marker for early detection of cancer, therapy monitoring, assessment of prognosis or prediction of therapy response. Here, we identified and validated breast cancer-specific methylation markers for diagnosis of the disease with high sensitivity and specificity.

**Methods:** 151 bio-banked samples were obtained for a randomized blind study; 65 subjects diagnosed with breast cancer (Stage I to IV), 15 subjects with benign breast disease, 32 subjects diagnosed with other cancer types (11 colorectal, 9 liver and 12 lung cancer), and 39 healthy donor samples. Cell-free DNA was then extracted from the samples, bisulfite converted, and DNA methylation was quantified by using the IvyGene Platform. Finally, the raw data were collected and analyzed to evaluate the test performance.

**Results:** A total of 53 of the 65 breast cancer samples were correctly identified for an overall calculated sensitivity of 89% with little difference between the sensitivity of detecting Stage I to Stage IV breast cancer (range 88% to 94%). The breast cancer subjects were correctly identified with 96% specificity. Additionally, 28 of 32 samples drawn from healthy donor subjects (specificity 95%) and all 15 samples drawn from subjects diagnosed with benign breast disease (specificity 100%) were also correctly identified. Of the samples drawn from subjects with cancer other than breast cancer, over 96% of lung cancer, colorectal cancer and liver cancer samples were correctly identified as not breast cancer.

**Conclusion:** The results demonstrate the high diagnostic potential of ctDNA methylation markers in the blood for the detection of breast cancer. In addition, a quantitative analysis of ctDNA provides an opportunity for non-invasive detection of cancer and its benefits can be anticipated to improve patient management and healthcare quality.

Circulating cell-free DNA in serum as a marker for the early detection of tumor recurrence in breast cancer patients

Alakesh Bera¹, Ofer Eidelman¹, Eric Russ¹, Adam Landa¹, John Karaian¹, Michael Eklund¹, Hai Hu³, Harvey B Pollard¹, Craig D Shriver² and Meera Srivastava¹. ¹Uniformed Services University, Bethesda, MD; ²Walter Reed National Military Medical Center, Bethesda, MD and ³Chan Soon-Shiong Institute of Molecular Medicine, Windber, PA.

Background: Quantitative estimation of circulating cell-free DNA (cfDNA) isolated from serum by noninvasive procedures can serve as a potential biomarker for the early detection of many cancers. However, a simple, straightforward technique is unavailable to estimate the cfDNA in clinical labs. Moreover, the prognostic value of cfDNA in patients with breast cancer (BrCa) is currently under debate. The aim of this study was to develop a simple yet effective quantitative method for measuring the cfDNA in serum and to eventually investigate the relationship between cfDNA and the occurrence of recurrence in BrCa patients.

Methods: A total of 240 patient cases (n=240) were selected and are comprised of different subtypes of breast cancer patients and control individuals. We selected 21 serum samples from patients which showed recurrence after 4-7 years of disease-free survival. For the compare studies, each of the recurrent and non-recurrent serum samples was incubated with the SYBR Green I (2 µM). A standard graph was also made with known DNA concentration to calculate the amount of cfDNA in these recurrent and non-recurrent serum samples. Additionally, a comparative study was also performed with the serum of patients with non-recurrent BrCa versus healthy patients.

Results: We develop a simple fluorescent based measuring technique which can easily estimate the cfDNA in one step. SYBR Green binds to DNA, and as a result, the fluorescence of SYBR Green increases substantially. Global Wilcoxon analyses were performed to compare the cfDNA amount between non-recurrent and recurrent patients. There is a significant difference in fluorescent intensities between recurrent patients' samples versus non-recurrent patients which are directly proportional to the cfDNA levels. The amount of cfDNA is higher in recurrent patient (ratio is 1.3 up; p= 0.03; AUC=0.76) compared to similar non-recurrent patients. While we compared the fluorescence data between normal/healthy patients versus non-recurrent is turned out as non-significant (healthy to non-recurrent ratio = 1.03; p= 0.20, AUC=0.61).

Conclusion: In this current study, we developed a straightforward one-step technique to measure the amount of cfDNA in serum, which can easily translate into a clinical diagnostic tool. To the best of our knowledge, this is the first report which demonstrates serum cfDNA as an early detection marker for recurrent breast cancer patients. The relatively high level of cfDNA in the serum of recurrent breast cancer patients compared to non-recurrent breast cancer patients indicates an uncovered circulating genetic information which triggers the cancer recurrence pathway to relapse cancer in the near future.
Analytical validation of an automated digital scoring protocol for Ki67: International multicenter collaboration study

Balazs Acs1,2, Samuel CY Leung3, Vasiliki Pelekanou1, Yalai Bai1, Sandra Martinez-Morilla1, Maria Toki1, Martin C Chang4, Abhi Gholap3, Anagha Jadhav5, Judith C Hugh6, Gilbert Bigras4, Arvydas Laurinavicius7, Renaldas Augulis7, Richard Levenson8, Austin Todd9, Tammy Piper9, Shakeel Virk10, Bert van der Vegt11, Daniel F Hayes12, Mitchell Dowsett13, Torsten O Nielsen3 and David L Rimm1.

1Yale School of Medicine, New Haven, CT; 2Karolinska Institute, Stockholm, Sweden; 3University of British Columbia, Vancouver, BC, Canada; 4Sinai Health System and University of Toronto, Toronto, ON, Canada; 5Optra Technologies, NeoPro SEZ, BlueRidge, Hinjewadi, India; 6University of Alberta, Edmonton, AB, Canada; 7Vilnius University Faculty of Medicine and National Center of Pathology, Vilnius University Hospital Santaros Clinics, Vilnius, Lithuania; 8University of California Davis Medical Center, Sacramento, CA; 9Biomarkers & Companion Diagnostics Group, Edinburgh Cancer Research Centre, Edinburgh, United Kingdom; 10Queen's University, Kingston, ON, Canada; 11University of Groningen, University Medical Center Groningen, Groningen, Netherlands; 12University of Michigan Comprehensive Cancer Center, Ann Arbor, MI and 13Institute of Cancer Research, London, United Kingdom.

**Background/Goal:** Ki67 expression has been a valuable prognostic marker in breast cancer, but has not seen broad adoption due to lack of standardization between institutions. Automation could represent a solution. Here we tested 3 automated digital image analysis (DIA) platforms including an open source platform to: (i) Investigate the reproducibility of Ki67 measurement across platforms with supervised classifiers performed by the same operator and by multiple operators. (ii) Compare accuracy of the 3 DIA platforms against outcome (prognostic potential). (iii) Assess inter-laboratory reproducibility of a calibrated DIA tool to evaluate Ki67 in breast cancer among 10 participating labs of the International Ki67 in Breast Cancer Working Group (IKWG).

**Methods:** The Mib-1 antibody (Dako) was used to detect Ki67 (dilution 1:100). HALO (H) (IndicaLabs), QuantCenter (QC) (3DHistech), QuPath (QP) (open-source software) digital image analysis (DIA) platforms were used to evaluate Ki67 expression. As a ground truth, we evaluated Ki67 LI with meticulous manual tissue segmentation using the Spectrum Webscope (SW) (Aperio). Calibration was performed using 30 ER+ breast cancer cases from phase 3 of the IKWG initiative where blocks were centrally cut and stained for Ki67. The inter-laboratory analysis was done with 10 participating laboratories divided into 2 groups where members within the same group were given the same set of images. The outcome cohort consisted of 149 breast cancer cases from the Yale Pathology archives in tissue microarray format. Intra-class correlation coefficient (ICC) was used to measure reproducibility with the pre-specified criterion for success being to exceed 0.80. Kaplan-Meier analysis supported with log-rank test was performed to assess prognostic potential.

**Results:** All 3 DIA platforms showed excellent inter-platform reproducibility (ICC: 0.933, CI: 0.879-0.966). Also, excellent reproducibility was found between all DIA platforms and the reference standard Ki67 values of SW (QP ICC: 0.970, CI: 0.936-0.986; H ICC: 0.968, CI: 0.933-0.985; QC ICC: 0.964, CI: 0.919-0.983). The intra-DIA reproducibility was also excellent for all platforms (QP ICC: 0.992, CI: 0.986-0.996; H ICC: 0.972, CI: 0.924-0.988; QC ICC: 0.978, CI: 0.932-0.991). Comparing each DIA against outcome, the hazard ratios were similar (QP=3.309, H=3.077, QC=3.731). The inter-operator reproducibility was particularly high (ICC: 0.962-0.995). As QP is open source software and also showed the lowest intra-DIA platform variability, we selected the QP platform to investigate inter-laboratory reproducibility among 10 IKWG labs. The different-section ICC across the 10 labs was 0.974 (CI: 0.954 - 0.986). The same-section ICC estimate was 0.984 (CI: 0.971-0.992) for group 1 and 0.978 (CI: 0.956-0.989) for group 2.

**Conclusions:** Our results showed outstanding reproducibility both within and between DIA platforms. We also found the platforms essentially indistinguishable with respect to prediction of breast cancer patient outcome. Automated Ki67 evaluation using a calibrated, open-source DIA platform (QuPath) met the pre-specified criterion of success in the multi-institutional setting. Assessment of clinical utility is planned.
Outcomes of diagnostic surgical biopsy in a population-based mammographic screening program

Holly J Keane, Kenneth Elder and Gregory B Mann. ¹Royal Melbourne Hospital, Melbourne, Victoria, Australia and ²University of California, San Francisco, San Francisco, CA.

Background: Screening mammography allows earlier diagnosis of breast cancer resulting in reduced breast cancer specific mortality, and potentially reduced morbidity from less intense treatment. These benefits may be offset by investigation and treatment of lesions that are detected on screening but which are eventually found to be clearly benign, have uncertain malignant potential, or are malignant but pose no threat to the person during her natural life. Abnormalities detected on screening mammograms are recalled for further assessment. The outcomes of assessment may be confirmation of the absence suspicious findings. It may be a core biopsy is performed to clarify the nature of a persistently indeterminate or suspicious lesion. In cases when workup has neither diagnosed malignancy nor excluded its possibility, diagnostic surgical biopsy (DSB) is recommended. DSB of a lesion where final pathology is benign is a harm from a screening program. The benefit of DSB where a core needle biopsy (CNB) has shown a high-risk lesion is dependent on identifying more significant pathology than that of the CNB. Trials are currently recruiting which investigate a non-operative approach for DCIS, yet DSB is still standard of care for less significant/benign pathologies in much of the world. We aimed to determine the outcomes for patients recommended for DSB in a population-based mammographic screening program in order to identify situations in which this may safely be omitted.

Methods: Ethics approval was obtained through Melbourne Health. Cases of DSB were reviewed from Northwest BreastScreen and Southern BreastScreen in Melbourne, Australia. Registry data was extracted including all patients where recommendation for DSB was made over a ten-year period (January 2004- December 2013). Patient demographics, imaging characteristics, core biopsy & surgical pathology were reviewed manually from individual BreastScreen files. Data points were entered to an Excell database. We reviewed assessment reports, tabulated indications for DSB, and surgical pathology reports for final histopathology.

Results: 1286 patients underwent DSB over the ten-year period. The overall upgrade rate to malignancy on DSB after non-malignant finding on CNB was 21.6% (14% to DCIS and 7.6% to invasive cancer). Atypical ductal hyperplasia (ADH) was the most common pathology identified on CNB generating recommendation for DSB. The overall upgrade rate for ADH was 31%, including 5.5% to invasive cancer, and 25.5% to DCIS. Further analysis of these ADH upgrades to DCIS revealed majority to low grade DCIS.

Discussion: A minority of patients with high-risk lesions, detected through screening mammography, were upgraded to malignancy on DSB in this cohort. The psychological and cost-effectiveness implications of this low upgrade rate to significant, life-threatening pathologies warrants further investigation. Future recommendations may involve including lesions of uncertain malignant potential or “high-risk” lesions in prospective observation and/or chemoprevention trials. This series suggests there may not be benefit in earlier diagnosis of the malignancies associated with ADH. Our data may therefore allow identification of groups of women who could be safely managed with less intensive treatment.
Impact of the 2018 ASCO/CAP HER2 focused update on human epidermal growth factor receptor-2 (HER2) testing in breast cancer: A retrospective review of a single institutional cohort

David G Hicks¹, Marcus D’Aguiar¹, Jill Henry¹, Loralee McMahon¹, Brandon Buscaglia¹ and Bradley Turner¹. ¹University of Rochester Medical Center, Rochester, NY.

**Background**: In the 2013 ASCO/CAP HER2 update, new recommendations for HER2 diagnostic criteria in breast cancer organized in situ hybridization (ISH) results into five categories; group 1 (amplified), group 2 (monosomy), group 3 (co-amplified), group 4 (equivocal) and group 5 (non-amplified). Patients falling into groups 2, 3 and 4 were potentially eligible for HER2 targeted therapy, however, there is uncertainty from limited prospective clinical trials that show patients in these uncommon groups would receive the same benefit as group 1. Concern over whether the interpretation criteria should be modified for these uncommon groups led to the recent publication of the 2018 HER2 focused update. This update has modified ISH criteria for groups 2, 3 and 4, recommending the final diagnosis take into consideration both immunohistochemistry (IHC) and ISH results. The publication of this new guideline has prompted us to investigate what impact this would have on our institution.

**Materials & Methods**: A retrospective review of the URMC pathology database revealed 2,281 cases that had undergone HER2 FISH analysis since the 2013 update. IHC for initial HER2 screening was used, followed by reflex testing of all 2+ results and cases with histopathologic discordance. All 2,281 FISH cases were sorted into their 5 HER2 categories based on the 2013 guidelines. The final HER2 diagnosis for groups 2, 3 and 4 were then re-determined after applying the new criteria presented in the 2018 focused update.

**Results**: The results from the 2,281 HER2 FISH cases are shown in Tables 1 and 2. The results for group 1 and group 5 cases remained the same. However, for ISH cases in groups 2, 3 and 4, there were alterations in the final HER2 results. All 25 monosomy cases, originally interpreted as HER2 positive by the 2013 guidelines, were now considered HER2 negative. All group 3 (co-amplified) cases remained positive (due to IHC 2+ results). The largest change was that the original 199 equivocal cases, based on the 2013 guidelines, became split into 198 HER2 negative (99.5%) and 1 HER2 positive (0.5%).

**Conclusion**: Comparison of the HER2 FISH cases between 2013 and 2018 revealed differences in the final HER2 status. Using the 2018 guideline, 13.72% (313 cases) of the 2281 cases were HER2 positive in contrast to 14.77% (337 cases) from 2013. While that is only a difference of 1.05%, the reclassification of 198 of 199 equivocal cases to negative indicates that 9.82% of the final HER2 results for the entire patient cohort was affected. With 266,000 new cases of breast cancer annually, the final HER2 status of approximately 26,000 patients and their potential eligibility for targeted-therapy would change. Further study of the clinical significance of these changes is warranted.

Tumor-infiltrating lymphocytes in invasive lobular breast cancer identify a poor prognostic sub-group

Jean-Christophe Tille1, Caroline Saint Martin2,3, Laetitia Fuhrmann2,3, Leanne De Koning2,3, Fabien Reyal2,3, Martine Piccart4, Youlia Kirova2,3, Paul Cottu2,3, Matthieu Carton2,3 and Anne Vincent Salomon2,3. 1University Hospital Geneva, Geneva, Switzerland; 2PSL Research University, Saint-Cloud, France; 3Institut Curie, Paris, France and 4Institut Jules Bordet, Bruxelles, Belgium.

Background:
Tumor infiltrating lymphocytes (TILs) are associated with an improved outcome in triple negative and HER2 breast cancers. Conversely, a recent pioneer study showed that TILs in infiltrating lobular carcinoma (ILC) were associated with a worse prognosis. We aimed at assessing the prognostic impact of TILs in a large cohort of primary surgically treated ILC with a long follow-up in a single institution.

Methods:
We retrospectively reviewed 459 ILC treated at the Curie Institute between 2005 and 2008. Clinico-pathological patients' characteristics were collected and all archived tumor slides were centrally reviewed for TILs quantification. We analyzed stromal TILs scored as a continuous variable. Cox analyses were performed for relapse free survival (RFS) and for overall survival (OS), and chi-square and Fisher test were performed to evaluate the correlation between TILs and other clinico-pathological variables. For statistical analyses, presence or absence of TILs was considered.

Results:
Patients had a mean age of 60.3 years and a median follow-up of 8.8 years, during which 74 local and/or distant relapse events occurred, among which 37 deaths due to the disease. The presence of TILs were significantly associated with greater tumor size (pT), positive nodal status (pN), molecular class (HER2 amplified), and specific morphological nuclear features such as high nuclear grade, multinucleation, macronucleoli and high Nottingham Prognostic Index class. Presence of intra-tumoral lymphocytes is significantly associated with a worse RFS (HR: 2.07 p=0.003) and OS (HR: 4.58 p<0.001) in a multivariate analysis, independently of chemotherapy.

Conclusion:
TILs are an independent prognostic factor associated with a poor outcome in ILC that are easy to assess on diagnostic biopsies. In order to elucidate the role of TILs in ILC, we will further characterize the immune infiltrate and integrate these results with DNA, RNA and protein analyses of the same carcinomas, in order to gain insight into their molecular features and to facilitate the identification of new therapeutic strategies for these ILC with TILs.
Apocrine morphology and LAR molecular subtype predict prognosis of TNBC patients with residual disease after neoadjuvant chemotherapy

Hiroko Masuda¹, Sakiko Miura¹, Kenichi Harano², Ying Wang³, Yuko Hirota¹, Yuki Matsunaga¹, Bora Lim³, Anthony Lucci³, Napa Parinyanilikut⁴, Hee Jin Lee⁵, Gyungyub Gong⁵, Arvind Rao³, Robert S Seitz⁶, Stephan W Morris⁶, David R Hout⁶, Seigo Nakamura¹, Debasish Tripathy³, Oi Harada¹,⑦, Savitri Krishnamurthy³ and Naoto T Ueno³. ¹Showa University, Tokyo, Japan; ²National Cancer Center Hospital East, Chiba, Japan; ³The University of Texas MD Anderson Cancer Center, Houston; ⁴Chulalongkorn University, Bangkok, Thailand; ⁵University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea; ⁶Insight Genetics, Inc., Nashville, TN and ⁷Kameda General Hospital, Kamogawa, Japan.

Background: TNBC molecular subtype classification updated by Lehmann et al. includes 4 subtypes: basal-like 1 and 2 (BL1), (BL2), mesenchymal (M), and luminal androgen receptor (LAR), and as a modifier of these subtypes, an Immunomodulatory (IM) gene expression signature. However, molecular subtypes have not been linked to morphological features of TNBC. Apocrine carcinoma has been proposed as a TNBC category that expresses androgen receptor. LAR-subtype TNBC has a poor response to neoadjuvant systemic therapy (NST). We hypothesized that defining the apocrine-featured TNBC by morphology and molecular subtype predict the prognosis of patients with residual disease after NST. Methods: We created the Pan-Pacific TNBC Consortium dataset, which contains paired samples of matched pre and post-NST TNBC tumors from 4 institutions. All patients received NST and didn't have a pathological complete response (pCR). Three pathologists examined hematoxylin and eosin-stained slides of 86 pre-NST samples and determined (1) the presence of apocrine differentiation, (2) the level of tumor-infiltrating lymphocytes (TILs), (3) the histological grade (HG), and (4) the rate of necrosis. These morphological features were compared among the subtypes. For a sample to be considered apocrine positive, apocrine differentiation had to be identified by 2 or more pathologists. Fisher's exact test was used to test the association of subtypes and morphological features. The log-rank test was used to compare disease-free survival (DFS). Results: Twelve of 24 (50%) apocrine-positive tumor samples were LAR subtype, and 12 of 17 (70%) LAR-subtype tumor samples exhibited apocrine differentiation. The other subtypes showed following: BL1, 11/44 (25%); BL2, 0/7 (0%); M, 1/10 (10%); unclassified, 0/8 (0%). The median follow-up time was 22 months. In all populations, 2-year DFS rates were higher in patients with apocrine-positive tumors than in those whose tumors did not exhibit apocrine differentiation (P = .027; 2-year DFS, 85% vs 54%). The LAR subtype was also associated with lower HG, although LAR tumors had a similar prognosis to the other subtypes. In the combined analysis of subtypes and apocrine differentiation, patients with apocrine-positive LAR tumors had a higher 2-year DFS rate than did those with apocrine-negative LAR tumors (P = .044; 2-year DFS, 88% vs. 30%). However, patients with apocrine-positive BL1 tumors had no better DFS than did those with apocrine-negative BL1 tumors (P = .133). TIL levels and the presence of the IM signature were positively associated (P = .01), and apocrine differentiation positivity tended to be negatively associated with TIL level (P = .06). Neither TIL level nor IM signature was associated with survival. Conclusion: Apocrine differentiation was associated with the LAR subtype of TNBC and better prognosis in patients who did not have a pCR. The LAR subtype alone did not predict DFS; however, LAR tumors with apocrine differentiation had a better prognosis than did LAR tumors without apocrine differentiation. Using a combination of morphologic and genomic testing may be helpful in determining the prognosis of patients with apocrine-positive TNBC tumors who have residual disease after NST.
Inter- and intra-laboratory variation in grading of ductal carcinoma in situ of the breast: A nationwide study in the Netherlands

Carmen van Dooijeweert¹, Paul J van Diest¹, Stefan M Willems¹, Chantal C Kuijpers¹, Lucy I Overbeek² and Ivette A Deckers².
¹University Medical Centre Utrecht, Utrecht, Netherlands and ²Foundation PALGA (the Nationwide Network and Registry of Histology and Cytopathology in the Netherlands), Houten, Utrecht, Netherlands.

Background:
A considerable part of ductal carcinoma in situ (DCIS) lesions may never progress into invasive breast cancer. Yet, standard treatment consists of surgical excision. Trials aim to identify a subgroup of low-risk DCIS that, under active surveillance, can safely forgo surgical treatment. These low-risk subgroups are in all trials solely based on histologic grade, which highlights the importance of accurate, consistent, and reproducible grading by pathologists. To improve standardization, we aimed to gain insight into laboratory-specific variation of DCIS grading in daily clinical practice.

Materials and methods:
All synoptic pathology reports of pure DCIS resection specimens between 2013-2016 were retrieved from PALGA, the nationwide Dutch Pathology Registry. Absolute differences in proportions of grade I-III between laboratories (inter-laboratory) were visualized using funnel plots, in which the proportions per laboratory are plotted against the number of DCIS per laboratory, with the national proportions per grade as target. Multivariable analysis to correct for case mix was performed by logistic regression, providing odds ratios (ORs) and 95% confidence intervals (CI) for high-grade (III) versus low-grade (I-II) DCIS per laboratory. Absolute differences of proportions of grade I-III between pathologists within laboratories (intra-laboratory) were also analyzed. Lastly, an online questionnaire was send to all pathology laboratories in the Netherlands to identify how pathologists determine histologic grade in daily clinical practice.

Results:
In total 4,952 DCIS cases from 36 laboratories were included, of which 12.5% were reported as grade I (range 6.1-24.4%), 39.5% as grade II (18.2-57.6%), and 48.0% as grade III (30.2-72.7%). After correction for case mix, 14 laboratories (38.9%) reported a significantly lower (n=4) or higher (n=10) proportion of high-grade DCIS than the reference laboratory. Adjusted ORs (95% CI) ranged from 0.52 (0.31-0.87) to 3.83 (1.42-10.39). Intra-laboratory analysis also showed significant differences between pathologists within 25% of the laboratories. The results of our questionnaire showed that pathologists mentioned numerous different guidelines as a reference for the histologic grading of DCIS, while 20.3% of them even stated that they grade DCIS (partially) based on intuition.

Conclusion:
We observed substantial inter- and intra-laboratory variation in the histologic grading of DCIS, which was not explained by differences in case mix. Therefore, there is an urgent need for nationwide standardization of grading practices, especially since the future management of DCIS may alter significantly depending on histologic grade.
Comparison of breast cancer molecular subtyping by Immunohistochemistry and by BluePrint® next generation RNA sequencing-based test at University Hospitals Leuven and Curie Institute Paris

Background
MammaPrint® (MP) and BluePrint® (BP) are microarray-based tests with MP being prognostic for distant recurrence and BP enabling stratification into breast cancer molecular subtypes (Luminal, HER2, Basal-type). Recently, a CE marked MP and BP targeted RNA Next Generation Sequencing (NGS)-based kit was developed at Agendia and validated at University Hospitals Leuven and Curie Institute Paris. Here we compare breast cancer molecular subtype stratification defined by immunohistochemistry (IHC) and by MP and BP NGS- and microarray- based tests.

Patients and Methods
In this study, 124 primary operable invasive breast cancer patients were included at University Hospitals Leuven and at Curie Institute (n=80 Leuven; n=44 Curie) with the following histological subtypes: ductal-NOS (n=100), lobular (n=16), mucinous (n=3), tubular (n=2), others (n=3). Patients with bilateral breast cancer or with >3 positive lymph nodes were excluded. Surrogate breast cancer subtypes based on IHC were defined as follows: luminal if ≥10% estrogen receptor (ER) expression; triple negative if <10% ER and progesterone receptor (PR) expression and HER2 stained negative by IHC and/or FISH; HER2+ if HER2 receptor stained positive (2+ or 3+) by IHC and/or FISH. Luminal subtypes were further stratified into Luminal A-like (HER2 negative, Ki-67<14%, PR≥20%) and Luminal B-like (HER2 negative or positive, Ki-67 ≥14%, PR<20%). When Ki-67% was not available, tumors with grade 1 or 2 were classified as Luminal A-like and with grade 3 as Luminal B-like. IHC subtypes were compared to the MP/BP NGS subtypes.

Results
Concordance between IHC and MP/BP NGS subtyping was 75.0% (93/124).

MP/BP NGS subtyping identified more low risk Luminal A tumors compared to IHC (54.0%, (67/124) vs 44.3% (55/124)). Notably, concordance was excellent for triple-negative and, to less extent for HER2 driven tumors (Luminal B-like-HER2 positive and HER2+).

**Conclusion**

This study shows a discordance of 25.0% between IHC and BP/MP NGS subtyping. This is in line with previous findings where IHC was compared to molecular subtyping based on microarray (Viale 2017, Whitworth 2014) underlining the complementarity of genomic testing in early stage breast cancer. Moreover, we observed a high concordance between NGS and microarray molecular subtyping, which suggests a successful translation of the MP/BP microarray test to a MP/BP NGS test.
Statistical modeling of influential variables affecting HER2-positivity in breast cancer: Final analyses from two large, multicenter, noninterventional studies in Germany

Josef Rüschoff¹, Annette Lebeau²,³, Hans Kreipe⁴, Peter Sinn⁵, Hans-Ulrich Schildhaus⁶, Thomas Decker⁷, Johannes Ammann⁸, Claudia Künzel⁹, Winfried Koch¹⁰ and Michael Untch¹⁰. ¹Institut für Pathologie Nordhessen and Targos Molecular Pathology GmbH, Kassel, Germany; ²Institut für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; ³Gemeinschaftspraxis für Pathologie, Lübeck, Germany; ⁴Institut für Pathologie, Medizinische Hochschule Hannover, Hannover, Germany; ⁵Sektion Gynäkopathologie, Pathologisches Institut der Universität, Heidelberg, Germany; ⁶Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany; ⁷Dietrich Bonhoeffer Medical Center, Neubrandenburg, Germany; ⁸Roche Pharma AG, Grenzach-Wyhlen, Germany; ⁹BDS Koch, Schwetzingen, Germany and ¹⁰HELIOS Klinikum Berlin-Buch, Berlin, Germany.

Background:
While HER2 testing in breast cancer (BC) has been routine for over a decade, testing quality remains a challenge. Currently, HER2-positivity rate is the only recommended quality indicator. However, the large, observational, prospective NIU HER2 study in Germany quantified the impact of patient- and tumor-related characteristics such as histologic grade, hormone receptor (HR) status, histologic subtype, age, and nodal status on HER2-positivity, indicating that these factors need to be considered when evaluating HER2-positivity as a measure of testing quality (Rüschoff et al. Mod Pathol 2017). We now report the final analyses from the multicenter EPI HER2 BC study (ML29763, NCT02666261) in Germany where we compared NIU and EPI study data, and aimed to validate the NIU study model.

Methods:
Data from eligible patients with invasive BC were collected (HER2 test result; patient- and tumor-related factors) and variables influencing HER2-positivity identified and compared between studies. The NIU study model was validated and its predictive power determined using newly collected data from the EPI study, with cutoff and variable coefficients from the previous NIU analysis. Additional promising variables were explored, and their relative influence investigated, using multiple stepwise logistic regression.

Results:
In total, 14,729 (EPI) and 15,281 (NIU) BC samples were analyzed. Distributions of the main variables were comparable; overall HER2-positivity rates were 13.47% (EPI) and 14.24% (NIU). Fitting the NIU study model to EPI study data demonstrated that all five covariates from the NIU study analyses significantly affected HER2-positivity (p < 0.01); the influence for each covariate differed only slightly between studies (in EPI, histologic grade had most influence followed by histologic subtype, HR status, nodal status, and age). Prediction profiles were used to visualize the relationship between the model-predicted probability of HER2-positivity and the five identified covariates, which showed good comparability between studies. The receiver operating characteristics area under the curve (ROC AUC) of the NIU model used to predict HER2-positivity in the EPI study data was close to that of the model fitted to the NIU data, thus successfully validating the NIU model. To further improve the model, the categorical HR status was replaced by estrogen receptor (ER) and progesterone receptor (PgR) expression. Inclusion of ER and PgR as continuous variables improved the predictive strength of the model (ROC AUC = 0.74; sensitivity = 0.76; specificity = 0.63). Based on this improved model, PgR status had the highest influence on HER2-positivity, followed by histologic grade, histologic subtype, nodal status, ER status, and age.

Conclusions:
Results from our analyses confirm the statistically and clinically significant influence of patient- and tumor-related factors on HER2-positivity, and highlight the necessity to integrate these factors into the quality control assessment of HER2 testing. Implementation of this model in routine practice may assist in addressing issues with interlaboratory variation, and help to identify centers with HER2 testing problems more accurately.
Clinical and histopathologic characteristics of breast cancer in very young patients

Brian S Finkelman¹, Luis Z Blanco¹ and Kalliopi P Siziopikou¹. ¹Breast Pathology Section, Northwestern University, Chicago, IL.

Background: While breast cancer risk increases with age, about 7% of breast cancer cases in the US are diagnosed in women <40 years of age. Evidence suggests that young breast cancer patients tend to have more aggressive disease subtypes, less favorable tumor biomarker profiles, higher risk of relapse, and poorer survival. However, there is no universally accepted definition of "young patients," and most studies have focused on premenopausal women or those <40 years of age, with some studies using age <35. To date, very little is known on the clinical and histopathologic characteristics of breast cancer in very young women, namely those ≤30 years of age. In this study, we describe such features in a cohort of very young women treated for breast cancer at our academic institution.

Methods: Our patient population consisted of all cases of invasive breast carcinoma at Northwestern Memorial Hospital in women <40 years of age at surgery between January 1, 2009, and December 31, 2015. Very young was defined as having an age ≤30. Histopathologic features including tumor size, grade, histologic type, presence of lymphovascular invasion (LVI), lymph node status, tumor markers (ER, PR, HER2) and Ki-67 proliferation rate were recorded. Cases in which specific histopathologic features could not be determined from available materials were excluded from the corresponding analysis. The use of neoadjuvant chemotherapy, type of surgery, and the use of prophylactic surgery on the contralateral side were also recorded and analyzed.

Results: A total of 301 invasive breast carcinoma cases were identified (age range 18-39). 40 cases of very young (age ≤30) women with breast cancer (13%) were identified. Nearly all very young patients were diagnosed with tumors of ductal histology (39/40, 98%). Just under half of these patients (19/40, 48%) had a T1 (<2 cm), 16/40 (40%) had a T2 (2-5 cm), and 2/40 (5%) had a T3 (>5 cm) tumor at the time of surgery. The majority of these carcinomas were grade 3 (25/39, 64%), 14/39 (36%) were grade 2, and none were grade 1 tumors. Over half of the tumors were highly proliferative with a high Ki-67 count of >20% (17/31, 55%). ER was expressed in 34/40 (85%), PR in 25/40 (63%) and HER2 in 9/40 (23%). LVI was present in half of the cases (20/40, 50%), and positive lymph nodes were identified in over a third (15/40, 38%) of the cases. Neoadjuvant chemotherapy was used in 9/40 (23%). Three patients (8%) had no residual carcinoma at the time of surgery post chemotherapy. Most of these very young patients chose a mastectomy (28/40, 70%), and 19/40 (48%) also underwent a prophylactic mastectomy on the contralateral side.

Conclusions: Our study is one of the largest to date to describe the characteristics of breast carcinomas in very young women (age ≤30). Poor pathologic features such as high tumor grade, high proliferation rate, and presence of LVI were seen in half or more of these very young patients. A high rate of positive lymph nodes was also seen. Mastectomy, often with contralateral prophylactic surgery, was the procedure of choice. Further studies evaluating the molecular characteristics of these tumors and the prevalence of underlying genetic mutations are under way in this unique population of very young breast cancer patients.
Are fine-needle aspiration (FNA)-derived cell blocks a useful tissue sample surrogate for testing conventional biomarkers and PD-L1 in breast cancer?

Sara Bravaccini¹, Sara Ravaioli¹, Andrea Rocca¹, Maria Maddalena Tumedei¹, Elisa Bucchi², Manuela Malmesi², Laura Medri³, Massimiliano Bonafè¹,⁴ and Maurizio Puccetti⁵. ¹Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, FC, Italy; ²Santa Maria delle Croci Hospital, Ravenna, Italy; ³Morgagni-Pierantoni Hospital, Forlì, FC, Italy; ⁴Alma Mater Studiorum, University of Bologna, Bologna, Italy and ⁵Imola Hospital, Imola, Italy.

**Background** The diagnosis of breast cancer (BC) is based on clinical examination in combination with imaging and confirmed by pathological assessment of core needle biopsy (CNB) or fine needle aspiration (FNA). The biological profile of the lesion is needed to define prognosis and guide therapy. Given the importance of an early and minimally invasive diagnosis, we aimed to verify whether the biological features detected in FNA-derived cytological material reflect the biological characteristics of surgical specimens.

**Methods** We used immunohistochemistry and fluorescence in situ hybridization (FISH) to study a panel of biomarkers (ER, PgR, Ki67 and HER2 in 93 patients, programmed death-ligand 1 (PD-L1) in 20 patients) in FNA-derived cell blocks of BC, comparing the results with those obtained on the histological specimens. Immunostaining was performed with the Ventana Benchmark XT system and the Ultraview DAB Detection Kit (Ventana Medical Systems). Confirm anti-ER (clone SP1, Ventana), Confirm Anti-PgR (clone 1E2, Ventana) and Ki67 (clone Mib-1, Dako, Carpinteria, CA, US) antibodies were used. Ventana PD-L1 (SP263) assay (Ventana Medical Systems) was used for PD-L1 immunostaining. HER2 status was analyzed by FISH using PathVysion kit (Abbott Molecular, Abbott Park, Illinois, IL, USA).

**Results** Median immunopositive values of ER, PgR Ki67, and PD-L1 were similar in cell blocks and surgical samples. Concordance for ER and PgR between FNA and histological samples was 98% and 84%, respectively. With regard to Ki67 and HER2 status, concordance between the two specimen types was 90% and 96%, respectively. PD-L1 expression analyzed in FNA-derived samples was 100% concordant with that of surgical specimens. Tumor subtype classification for triple-negative and HER2-positive tumors in FNA samples was always concordant with the subtype determined in surgical material.

**Conclusions** We showed that biological marker determination in FNA-derived cell blocks is feasible and provides useful information and comparable results with those obtained by histological evaluation. Given the low cost of the procedure and its minimal impact on patients, that cytological samples could be used as an alternative to tissue samples for early BC biomarker evaluation to facilitate the planning of tailored neoadjuvant therapy.
Computer vision detects morphological correlates of HER2 positive breast cancer in H&E stained histological images

Shubham Dhage¹, Deepak Anand¹, Neeraj Kumar², Peter H Gann² and Amit Sethi¹. ¹Indian Institute of Technology Bombay, Mumbai, India and ²University of Illinois at Chicago, Chicago, IL.

Background/Objectives: The determination of HER2-positivity by IHC or FISH is critical for identifying patients most likely to benefit from anti-HER2 therapy. However, these methods do not always provide an accurate indication of HER2 overactivity, which can occur without gene amplification or overexpression of the HER2 protein. Our study objective was to determine if a deep learning convolutional neural network (CNN) could be trained, using IHC HER2 staining, to learn a morphological signature for HER2 positivity in H&E stained slides.

Methods: For training, we used H&E images (whole slides scanned at 40x) from 10 HER+ patients (IHC 3+) and 15 HER2− patients (IHC 0 or 1+) along with their adjacent HER2 IHC images. We first annotated non-cancer regions in H&E images. We then identified tumor regions in HER2 IHC that were positive (intense/complete circumferential stain) or negative (no or weak stain). We ignored any regions with equivocal IHC response as well as whole slides of IHC 2+ patients. For rigorous testing, slides from a separate set of 7 HER2+ and 19 HER2− patients were used. Digitized slides and expert consensus IHC HER2 status for each patient were provided as part of an international HER2 IHC scoring competition organized by the University of Warwick.

The computer vision pipeline comprised four-stages. First, we color-normalized the H&E images to reduce unwanted color variation between slides. Second, a pre-trained neural network (NN1) marked all nuclear centroids to make it easier for subsequent stages to focus on nuclear morphology and inter-nuclear spatial arrangements. Third, a neural network (NN2) trained on sub-images of size 100x100 centered at nuclear centroids classified nuclei as non-cancer vs. cancer. Fourth, a final neural network (NN3) sub-classified cancer nuclei into HER2+ or HER2−. In H&E images of held-out test patients, the percent of cancer nuclei scored as HER2+ was analyzed.

Results: NN2 had a classification accuracy exceeding 97% on a validation set of 25,000 nuclei set aside from training patients, while NN3 had a validation accuracy of 88% on 7,500 test nuclei. On the set aside test patients, among the seven HER2+ patients an average of 49.8% cancer nuclei were scored HER2+, while among the 19 HER2− test patients the corresponding proportion was only 24.7% (p < 0.01). The AUC of binary classification of test patients into HER2+/− based on percent of HER2+ nuclei was 0.815. Upon closer inspection, the H&E morphology of some of the misclassified HER− patients showed visual similarity to the correctly classified HER2− patients and vice versa.

Conclusions: Even when morphological patterns associated with cancer subtypes are too subtle for humans to reliably detect, H&E stained slides analyzed by CNNs may be able to geographically map a HER2 signature. It is unclear if misclassification with respect to IHC status is a reflection of morphological confusion or discordance between genomic subtype and IHC response. By training multiple neural networks to detect morphological signatures corresponding to different molecular subtypes of breast cancer, we may be able to detect and study intra-tumor heterogeneity in a cost effective and/or complementary way compared to multi-region sequencing.
Comparison of RT-qPCR with consensus immunohistochemistry by three pathologists for ER, PR, HER2 and Ki-67 in Chinese breast cancer patients

Xiaodong Teng¹, Xingmin Li², Shaoting Xu¹, Jianfeng Zhang³, Kerstin Hartmann⁴, Mark Laible⁴, Rainer Hipfel⁴, Yanfeng Bai¹, Xiaoqun Ba¹, Zihan Wu¹, Ralph M Wirtz², Shujin Liu² and Sahin Ugur⁶. ¹The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; ²Shuwen Biotech Co. Ltd., Zhejiang, China; ³The First Affiliated Hospital of Zhejiang University Medical College, Shengzhou Branch, Shaoxing, China; ⁴BioNTech Diagnostics GmbH, Mainz, Germany; ⁵STRATIFYER Molecular Pathology GmbH, Colgne, Germany and ⁶BioNTech AG, Mainz, Germany.

Background
During the diagnostic work-up of breast carcinomas, immunohistochemistry (IHC) is the currently used method for assessing the expression of estrogen- (ER) and progesterone-receptors (PR), human epidermal growth factor receptor 2 (HER2) as well as of Ki-67 as a marker of tumor cell proliferation. In this study, we analyzed the concordance of these four breast cancer biomarkers between the RT-qPCR- and IHC-based (evaluated by three independent pathologists) determinations.

Methods
The expression of ER/E‡R1, PR/PGR, HER2/ERBB2 and Ki-67/MKI67 was determined in 269 FFPE breast cancer samples with tumor content >20% from Chinese patients. For IHC, the samples were freshly cut, stained and assessed by three independent pathologists using the same scoring methods in a blinded fashion (positivity defined as: ER/PR ≥1%, HER2 >2+ and Ki-67 ≥20%). Measurement of the markers on the mRNA level was done on total RNA extracts prepared from whole tissue sections from the same FFPE blocks using the CE-marked RT-qPCR based IVD MammaTyper® on a Cobas® z480 qPCR cycler. IHC assessments of the three pathologists were compared to each other with regard to concordance of positive/negative results. Subsequently, agreement of RT-qPCR and IHC results for each marker and in samples in which the three pathologists had a consensus positive/negative IHC result was determined. Furthermore, we compared the MammaTyper® assessments from a subset of whole FFPE sections to data obtained from paired samples enriched for invasive carcinoma via macrodissection.

Results
From the 269 samples, 256 were available for final analysis. When excluding cases with discordant IHC callings between the three pathologists (6.0% for ER; 7.4% PR; 4.1% Her2; 17.1% Ki-67)) the concordance to the RT-qPCR determination and consensus IHC-based analysis displayed an excellent agreement for ER (OPA: 95.4%, PPA: 97.5%, NPA: 91.5%, Kappa: 0.897), PR (OPA: 91.1%, PPA: 89.6%, NPA: 93.1%, Kappa: 0.820) and HER2 (OPA: 97.1%, PPA: 91.9%, NPA: 100.0%, Kappa: 0.936). For cancer MKI67 mRNA and Ki-67 protein expression, a lower but still good concordance was found (OPA: 90.1%, PPA: 91.8%, NPA: 83.3%, Kappa: 0.707). In addition, we could demonstrate an excellent agreement of quantitative RT-qPCR measurements between whole surface and paired tumor-enriched samples in 99 Chinese breast cancer patients with R² of 0.927 for ER, 0.926 for PR, 0.923 for HER2 and 0.908 for KI67. Even under highly standardized IHC scoring conditions, the discordance rates in the RT-qPCR marker callings with 0.0% for ESR1, 5.0% for PGR, 3.0% for ERBB2, 13.1% for MKI67 were lower than disagreements by three pathologists on the identical slide.

Conclusion
Standardized determination of the breast cancer biomarkers ER, PR, HER2 and Ki-67 on the mRNA level shows high concordance to a consensus IHC determined by three experienced pathologists indicating that RT-qPCR may be a valid alternative for determining the four breast cancer biomarkers. In line with previous research we could show on a large set of samples that macrodissection is not required for reliable assessment of the four breast cancer markers in clinical FFPE samples.
Inter- and intra-laboratory variation in grading of invasive breast cancer: A nationwide study in the Netherlands

Carmen van Dooijeweert¹, Paul J van Diest¹, Stefan M Willems¹, Chantal C Kuijpers¹, Lucy I Overbeek² and Ivette A Deckers².
¹University Medical Centre Utrecht, Utrecht, Netherlands and ²Foundation PALGA (the Nationwide Network and Registry of Histology and Cytopathology in the Netherlands), Houten, Utrecht, Netherlands.

Background
Histologic grading is one of the best established prognostic factors in invasive breast cancer (IBC) and is used to guide patient management. Yet, the level of inter- and intra-observer agreement does not reach high enough clinical standards. To improve standardization, we aimed to gain insight into laboratory-specific variation in histologic grading.

Methods
All synoptic pathology reports of IBC resection specimens between 2013-2016 were retrieved from PALGA, the nationwide Dutch Pathology Registry. All lesions were graded according to the modified Bloom and Richardson guideline, which combines assessment of cell morphology (nuclear polymorphism), measurement of differentiation (tubular differentiation) and assessment of proliferation (mitotic count). Absolute differences in proportions of grade I-III and the three components of grading between laboratories were compared to the national distributions. For logistic regression analyses, grade was dichotomized into high- and low-grade by two alternative definitions for high-grade IBC (either solely grade III or grade II-III). Multivariable logistic regression, to correct for case mix (age, tumor size, type of surgery, histologic subtype, ER/PR-receptor status, HER2-receptor status), provided two laboratory-specific odds ratios (ORs) and 95% confidence intervals (CI) for high versus low-grade IBC compared to the reference laboratory.

Findings
In total 33,792 IBC cases from 39 laboratories were included, of which 28.1% were reported as grade I (range 16.3-43.3%), 47.6% as grade II (range 38.4-57.8%), and 24.3% as grade III (range 15.5-34.3%). More than half of the laboratories (22/39) showed proportions outside the 95% confidence limits of the national proportion for both grade I and grade III, followed by 41.0% of the laboratories for grade II. After case mix correction, 20 laboratories (51.3%) showed at least one significantly higher or lower OR than the reference laboratory. Four laboratories (10.3%) showed significantly deviant ORs on both analyses. Most variation between laboratories was observed for nuclear polymorphism. Significant grading differences were also observed between pathologists within 62.5% of the laboratories that could be analyzed. Overall, the indication for adjuvant chemotherapy was dependent on histologic grade in 29.9% of patients.

Conclusion
We observed substantial inter- and intra-laboratory variation in the histologic grading of IBC, which may likely influence treatment decisions and subsequently patient outcome as the indication for chemotherapy depends on histologic grade in almost every one in three patients.
Digitalizing immunohistochemistry analysis (IHC) with quantitative dot blot analysis (QDB) by absolute quantification of biomarkers in FFPE specimens

Jiandi Zhang¹, Wenfeng Zhang¹, Guohua Yu², Fangrong Tang¹ and Jiahong Lv¹. ¹Quanticision Diagnostics, Inc, Chapel Hill, NC and ²Qingdao University, Yantai, Shandong, China.

Purpose: The feasibility of Quantitative Dot Blot (QDB) method for absolute quantification of diagnostic biomarkers was investigated here using diagnostic antibodies for biomarkers in breast cancer tissues, including 4B5 and EP3 for Her2, MIB1 for Ki67, SP2 for Estrogen Receptor and SP1 for progesterone receptor (PR) in more than 300 FFPE specimens. The specificity and accuracy of this method, and the inter-relationship among biomarkers were explored by the absolute expression levels of these biomarkers.

Methods: FFPE specimens of 332 breast cancer patients were provided by local hospital, tissue slices of 2X15 um was de-paraffined and total protein was extracted for QDB analysis, with each sample measured in triplicate in three independent experiments. Purified protein standards were included to convert the measurement into absolute levels. IHC and FISH results from local hospital were used to validate the sensitivity and specificity of QDB method.

Results: The results show high consistency with intra-cv less than 7% and inter-cv less than 14%. With Her2, 99.5% concordance was achieved with IHC method, and 92 to 94% concordance with FISH analysis. Both Her2 level and Ki67 levels were significantly increased in patients at grade III based on Nottingham histologic scores.

Conclusion: The QDB method was used here to achieve digitalization of biomarkers in breast cancer tissue with existing diagnostic antibodies for IHC analysis. The method is simple, objective, consistent, comprehensive and suitable for high throughput analysis. We expect this method to be extended to other diagnostic IHCs with existing diagnostic antibodies, and the easy adoption of this method in clinical practice should have instant impact on pathological practice.
The effect of the 2013 American Society of Clinical Oncology/College of American Pathologists (ASCO/CAP) guidelines in HER2 positivity rates among women with breast cancer in SEER registries

Xuechen (Kathryn) Wang, Nan Hu, Kimberly Herget, Baran R Cinbis and Evin H Gulbahce. 1University of Utah, Salt Lake City, UT; 2University of Utah, Utah Cancer Registry, Salt Lake City, UT and 3Skyline High School, Salt Lake City, UT.

Introduction: The American Society of Clinical Oncology/College of American Pathologists (ASCO/CAP) revised the HER2 testing guidelines in breast cancer (BC) which was published in December 2013, practically becoming effective in 2014. Since then, many studies reported a significant increase in HER2 positivity rate in BC. Although HER2 has been routinely evaluated in BC for over a decade, HER2 status was not included in SEER registries until 2010. The aim of this study is to look at the effect of the 2013 ASCO/CAP guidelines on HER2 status in the SEER database that captures approximately 28% of all cancers in the US.

Material and Methods. Using data from 18 SEER cancer registries between the years of 2010-2015 when HER2 status for breast cancers was available, women with invasive BC were identified and their HER2 status and race was recorded. The Chi-square test was used to test the significance between positive proportions before and after the new ASCO/CAP guidelines were effective. Logistic regression was used to test if the changes in positivity rate were the same among different races. All calculations were made after excluding cases with unknown/missing HER2 status.

Results: We identified 376,278 women diagnosed with invasive BC between the years 2010-2015. HER2 positivity before 2014 (2010-2013) was 14.4% compared to 15.6% after 2013 (2014-2015) (p<0.001). HER2 positivity increased in all races after 2013. There was no significant difference in the increase of HER2 positivity between whites and blacks after the new guidelines went into effect. Unknown/missing HER2 status continually decreased over the study period from 7.4% in 2010 to 5.3% in 2015. Overall unknown/missing HER2 was significantly different among races: 6.5% in whites; 7.1% in blacks; and 6.2% in other races (p<0.01).

Conclusion: Revised ASCO/CAP HER2 guidelines significantly increased HER2 positivity rates in SEER registries from 14.4% to 15.6% after implementation started in 2014. HER2 positivity increased in all races after 2013. Unknown/missing HER2 status is significantly different among different races. Blacks have highest unknown/missing HER2 status in SEER registries.
Pathway level complementarity of germline and somatic events in breast cancer

Tao Qing¹, Michal Marczyk¹, Vikram Wali¹, Vignesh Gunasekharan¹, Gauri Patwardhan¹, Lajos Pusztai¹ and Christos Hatzis¹.
¹Yale University, New Haven, CT.

Background: Progression from a normal cell state to cancer requires multiple genomic hits in key regulatory pathways. In the case of hereditary cancer syndromes, some of these hits occur in the germline, but additional somatic mutations are required for malignant transformation. We hypothesize that this paradigm could be extended to sporadic cancers as well. What somatic mutation function as a cancer driver event may be determined by the constellation of germline variants a person is born with. We propose that even rare, non-recurrent, high functional impact germline variants in genes involved in cancer-related pathways could influence the biological impact of somatic mutations in other cancer-related genes. The goal of the current analysis was to examine associations between pathway alterations caused by high functional impact germline variants or somatic mutations in the “hallmarks of cancer” pathways in breast cancer.

Methods: We obtained germline DNA sequencing and copy number variation (CNV) data from the breast cancer TCGA cohort. After population clustering with the HapMap cohort, we selected a homogeneous group of 796 patients of Western European ancestry and downloaded the matching somatic mutations (SNVs and INDELs) that were available for 750 cases, that comprise the current study population. Germline CNVs were classified as recurrent or rare losses or gains. Potentially pathogenic germline variants (SNPs) were obtained from the PanCancer Altas project. All germline or somatic mutations were mapped at the gene level to the 50 Cancer Hallmarks pathway collection. We designated a pathway mutated if at least 1 gene had a germline or a somatic mutation. Complementarity between pathway alterations by germline and somatic events were evaluated using the Fisher exact test adjusted for multiple comparisons.

Results: At the germline level, 2,057 genes were affected by CNVs (mean 30, range 3-151 genes/patient), and a total of 43 genes carried germline pathogenic SNPs that affected 13.8% of the patients. At the somatic level, we detected 40,881 high functional impact mutations (mean 54.3, range 1-3889 mutations/patient) in 13,080 genes (mean 50.8, range 1-3166 genes/patient). The 50 Cancer Hallmark pathways contained 4386 genes (mean 146.5, range 32-200 genes/pathway), and were mutated in the majority of the patients (85% germline, 93% somatic). Several pathways, such as HEME_METABOLISM, INTERFERON_ALPHA_RESPONSE, and KRAS_SIGNALING, were frequently affected by germline alterations, while the somatic mutations were most frequently involved in the COMPLEMENT, E2F_TARGET, and UV_RESPONSE_UP. Interaction analysis revealed co-occurrence between MYC_TARGETS_V1 (germline) and UV_RESPONSE_DN (somatic) or MTORC1_SIGNALING (somatic) (p<0.01), and TNFA_SIGNALING_VIA_NFKB (germline) and IL6_JAK_STAT3_SIGNALING (germline) with E2F_TARGETS (somatic) (p<0.01). We also observed an exclusive relationship between germline alterations in BILE_ACID_METABOLISM and somatic mutations in COMPLEMENT pathway (p<0.01).

Conclusions: Our results highlight the importance of pathway-level analysis of germline alterations in breast cancer, which might help to understand the interrelationship between germline and somatic alterations in breast cancer.
Casting a wide net: Finding actionable results in non-breast cancer (BC) genes on multi-gene panel testing (MGPT) in a BC cohort

Samantha Culver¹, Lindsay Kipnis¹, Samantha Stokes¹, Brittany Bychkovsky¹, Rochelle Scheib¹, Huma Rana¹ and Judy Garber¹.
¹Dana-Farber Cancer Institute, Boston, MA.

Background: MGPT for hereditary cancer syndromes allows for concurrent analysis of genes associated with many different cancer types. This may lead to the identification of unexpected mutations in genes with no BC link. The objective of this study was to examine the landscape of pathogenic mutations in a BC cohort who underwent MGPT, to assess if there was clinical suspicion for identified mutations and if the results would affect subjects' medical management.

Methods: Retrospective review of subjects with BC seen at a single institution who underwent MGPT from 1/1/15-5/31/18 was conducted. MGPT was defined as testing of more than the 9 genes associated with BC (ATM, BRCA1, BRCA2, CDH1, CHEK2, PALB2, PTEN, STK11, TP53). Deidentified pedigrees were analyzed by genetic counselors to determine whether there was clinical suspicion of the presence of the mutations using national testing guidelines or clinical diagnostic criteria.

Results: Among 3044 subjects, 365 (12%) were found to have one pathogenic mutation in at least one cancer susceptibility gene. Subjects with mutations in APC I307K, moderate-penetrance BC genes (NBN, RAD50, BARD1), and MUTYH were excluded from further analysis. We identified 52 pathogenic mutations in genes not typically associated with risk for BC in 51 (2%) subjects (table 1). There was clinical suspicion for the identified mutation in 17 (33%).

Conclusion: Of 3044 BC patients who underwent MGPT, 2% were found to have a pathogenic gene mutation that would have been missed by a smaller BC gene panel. Medical or surgical management would be affected by the MGPT result in 86% of subjects. Only 6% of subjects with genetic risk for ovarian cancer had a family history of this disease. The single FH and 3 of 4 VHL mutations are only associated with disease in the biallelic state; these findings do not affect the subjects' care, but have implications for reproductive risk. The HOXB13 mutations were found in female subjects only, but would have implications for their male relatives. NF1 mutations are associated with BC risk, but were included in this analysis due to a historically distinct clinical phenotype. Only 50% of NF1+ subjects had a clinical diagnosis or family history of NF1. In all cases, cascade testing was offered to at-risk family members, allowing for cancer and reproductive risk stratification and management. This study demonstrates how comprehensive MGPT can provide a more complete and personalized cancer risk assessment for BC patients and their families.
Germline potentially pathogenic variants in breast cancer intrinsic molecular subtypes are not associated with somatic TMB

Elias Obeid¹, Sanjeev B Reddy², Lori J Goldstein¹, Mary B Daly¹, Stephen C Benz², Michael J Hall¹ and Christopher Szeto². ¹Fox Chase Cancer Center, Philadelphia, PA and ²NantHealth, Culver City, CA.

Background: Breast cancer (BC) is a heterogeneous disease. It is estimated that 5 to 10% of all BC to have a germline genetic predisposition. A 50-gene assay (PAM50) identifies 5 intrinsic molecular subtypes (IMS): Luminal A, Luminal B, HER2-enriched, Basal-like, and Normal-like. Basal-like breast cancers are enriched for BRCA1/2 germline mutations. Deleterious mutations in BRCA1/2 or other DNA-damage repair (DDR) genes may increase tumor mutational burden (TMB), a biomarker for response to checkpoint inhibition therapy. We sought to determine the spectrum of germline mutations in molecular BC subtypes (IMS), and their relation to somatic TMB. Methods: We performed a retrospective analysis of data from NantHealth database. RNAseq was used to classify breast tumors into IMS. Germline variants within putative driver genes (COSMIC v.76) were detected in analysis of 181 whole-genomes and 89 whole-exomes sequenced using Illumina chemistry. Classification of germline variants into potentially pathogenic variants (pPv) was determined using ClinVar database annotation. Patients were categorized as TMB-high by thresholding on >200 non-synonymous exonic somatic mutations as was previously reported. Results: A total of 270 BC patients with comprehensive omics profiling (germline DNAseq, somatic DNAseq, and somatic RNAseq) were available for this analysis. The mean age (±SD) was 56.4 (± 12.5) years (range 20.8-86.5). Forty-six patients (17.0%) were classified TMB-high. The IMS distribution was 40.7% Luminal A, 31.5% Luminal B, 5.9% HER2-enriched, 21.5% Basal-like, and 0.37% Normal-like. Over 200 unique germline variants were detected of which 98 were pPv according to ClinVar annotation. These pPv spanned 21 genes, 7 of which are directly related to DDR. One hundred and four patients had ≥1 pPv (78 had only 1 pPv, and 26 had >1 pPv). The most common pPv were APC (5.9%), BRCA2 (5.2%), TSC2 (4.4%), BRCA1 (3.7%), SDHB (3.3%), SDHD (3.3%), TSC1 (3.0%), PMS2 (3.0%), MUTYH (2.6%), MSH2 (1.5%) and MSH6 (1.5%). BRCA1 and especially BRCA2 pPv were mostly seen in the basal-like patients. Luminal B had distinctly more germline pPv in PMS2, BRCA1 & BRCA2 than Luminal A. TMB-high patients were present in all 4 major IMS types; Her2-enriched 37.5%, Luminal B 23.5%, Basal-like 17.2%, and Luminal A 9.1%. Conclusion: We identified differential distribution of germline pPv in BC IMS. Of the pPv found, APC was the most commonly detected pPv across subtypes, while BRCA1/2 pPv were clustered in Basal-like subtype, and PMS2 in Luminal B subtype. 17% of all patients had a pPv within at least one DDR gene, that potentially may benefit from targeted therapy. Despite IMS types having distinct germline pPv profiles especially in DDR genes, there was no association with subsequent somatic TMB. This suggests that either 1. somatic events are the primary drivers of TMB, or 2. that germline variants with either unknown or benign significance need to be revisited. Future analysis in a larger demographically well-annotated dataset (commercial data, ExAC, other) or via functional studies should be considered.
Genetic testing contributes significantly to improved identification of women eligible for increased breast cancer screening compared to the Tyrer-Cuzick risk model

Heidi M Gorringe¹, Eric Rosenthal¹, Brian Morris¹ and Susan Manley¹.
¹Myriad Genetic Laboratories, Inc., Salt Lake City, UT.

**Background:** Increased screening, including breast MRI, is recommended for women carrying pathogenic variants (PVs) in certain breast cancer risk genes, as well as women with an estimated remaining lifetime risk of breast cancer >20% based on risk models such as Tyrer-Cuzick (TC). We determined the extent to which genetic testing identifies women as candidates for increased screening who would not have been flagged using the TC model.

**Methods:** We evaluated 100,318 women who underwent clinical genetic testing for suspicion of hereditary breast cancer risk between June 2017 and June 2018. Testing with a 28 gene pan-cancer panel included 5 established breast cancer risk genes for which there are National Comprehensive Cancer Network (NCCN) recommendations for increased screening including breast MRI (*BRCA1, BRCA2, ATM, CHEK2, PALB2*). A remaining lifetime breast cancer risk estimate was calculated using TC V 7.02, unless the woman was ineligible due to a breast cancer diagnosis, age over 85, or if the sample was submitted without any of the necessary TC data. Risk estimates were calculated entering the *BRCA1/2* status as unknown.

**Results:** 4,640 (4.6%) women were found to carry a PV in one of the five genes, with 57.0% of the PVs in *BRCA1* or *BRCA2*, and 43.0% in *ATM, CHEK2* or *PALB2*. Among the women with a PV, 1,479 (31.9%) had a diagnosis of breast cancer, and 407 (8.8%) were ineligible for TC for another reason. A TC risk estimate was calculated for 2,754 women, of whom 41.5% did not meet the 20% threshold using TC. Table 1 shows the breakdown for each gene by age at the time of testing. Women with PVs in *BRCA1* were the least likely to have a TC score <20% and those with PVs in *BRCA2* and *ATM* were the most likely to fall below the 20% threshold. Remaining lifetime risk declined with age in all groups.

**Table 1.** Percentage of women carrying PVs in breast cancer risk genes with a remaining lifetime risk of breast cancer risk estimated at <20% by Tyrer-Cuzick.

**Conclusions:** Among the women included in this analysis, the TC model failed to identify approximately 40% of women eligible for high risk breast cancer screening due to PVs in breast cancer risk genes. This demonstrates that risk models based on clinical factors alone will fail to identify a significant fraction of women who are candidates for modified medical management. Additionally, it may be desirable to re-evaluate setting thresholds based on remaining lifetime risk, since this dramatically reduces the likelihood that high-risk women will be flagged for increased screening at older ages, when their immediate risk of a breast cancer diagnosis is likely to be highest.
Multi institutional effort for contributing with the clinical classification of variant of uncertain significance in BRCA1 and BRCA2 genes

Dirce Maria Carraro¹, Edenir I Palmero⁴, Henrique C Galvao⁴, Carolina M Berra¹, Rafael C Brianese¹, Giovana T Torrezan¹, Maria N da Cruz Formiga¹, Fernanda T de Lima³, Gabriela C Fernandes⁴, André E de Paula⁴, Rodrigo D Michelli⁴, Angelica M Gutierrez Barrera² and Banu K Arun². ¹AC Camargo Cancer Center, Houston, TX; ²University of Texas - MD Anderson Cancer Center, Houston, TX; ³Albert Einstein Hospital AC Camargo, Sao Paulo, Brazil and ⁴Barretos Cancer Hospital, Barretos, Brazil.

BRCA variants of unknown significance (VUS) occur in approximately 10% of genetic testing. The clinical interpretation of these VUS is a crucial step in the reporting and counseling process. The likely pathogenic, uncertain, and likely benign categories include some level of uncertainty as to whether the variant is related the the disease. Much of the data regarding variants is proprietary or unpublished, presenting a barrier to reclassifying inconclusive results. Therefore, the aim of this study was to compile and compare VUS in BRCA1/2 in Hispanic patients with breast cancer at 4 collaborating international institutions: UT MD Anderson Cancer Center (USA), AC Camargo Cancer Center (Brazil), Barretos Cancer Hospital (Brazil) and Albert Einstein Hospital (Brazil).

Each institution queried for patients with BRCA1/2 testing. Missense variants either not reported in ClinVar database or those classified as “conflicting interpretations of pathogenicity” were compiled in this study. All VUS were assessed by four computational prediction software (SIFT, Polyphen2, CADD and REVEL) and classified in five categories according to the risk of pathogenicity. Clinical variables (age, tumor type and tumor immunophenotype) were also assessed were available.

A total of 327 supposedly unrelated breast cancer patients and of BRCA1/2 missense variants of unknown clinical significance were identified (87 of BRCA1 and 242 of BRCA2). Here, we detected 271 different VUS (73 in BRCA1 and 198 in BRCA2), which were classified in five classes of estimated pathogenicity (very high, high, medium, low and very low risk of pathogenicity), according to the number of in silico programs classifying the variant as probably damaging. In BRCA1, 48% of variants and 29% of BRCA2 were classified as very high/high risk. The age of tumor onset (n = 252) did not differ between the stratified risk categories for both genes. We evaluated the occurrence of the same VUS in more than one institution and identified 4 variants of BRCA1 that had carriers in two institutions; and 10 and 2 variants of BRCA2 with carriers in 2 and 3 institutions, respectively. From the 16 VUS identified in more than one institution, three variants were classified as very high or high risk of pathogenicity, one in BRCA1 (p.A1789T) and two in BRCA2 (p.P94S and p.R2784Q). Interestingly, the p.R2784Q was identified in AC Camargo and Barretos Hospitals and a different variant in this same amino acid was identified in one patient from MD Anderson (p.R2784L). In both genes, we identified a significant enrichment of variants occurring in known functional domains in the very high/high risk categories, when compared to the other categories.

The information that has been gained in this study will aid to the classification of VUS by co-segregation analysis of probands and their family members. The definition of pathogenicity will be important in regards to their personalized risk management options (increased surveillance, preventive surgery or normal screening). This is one of the global approaches to identify women at increased breast and ovarian cancer risk via BRCA mutation classification.
Limitations of direct-to-consumer genetic screening for HBOC: False negatives, false positives and everything in between

Edward D Esplin¹, Eden Haverfield¹, Shan Yang¹, Blanca Herrera¹, Michael Anderson¹ and Robert L Nussbaum¹. ¹Invitae, San Francisco, CA.

Background
Genetic screening of unaffected individuals for hereditary breast and ovarian cancer (HBOC) risk is a growing opportunity for personalized preventive medicine. The FDA recently authorized a direct-to-consumer (DTC) test to report on 3 BRCA1/2 variants, commonly found in individuals of Ashkenazi Jewish (AJ) heritage, out of more than 1000 known. Here we define the probability that DTC genetic screening for the 3 BRCA1/2 AJ founder variants would falsely reassure individuals of AJ and non-AJ ancestry of low risk for hereditary cancer syndromes (HCS). We also assess the frequency of false positive results reported by third parties from raw genotypes, which are routinely provided to clients who submit them for cancer risk analysis.

Methods
We analyzed de-identified data on three cohorts: 1) An indication-based cohort of 119,328 patients referred by healthcare providers for HBOC genetic testing due to personal or family history, 2) a screening cohort of 5,170 patients without personal or family history who had BRCA1/2 testing as a health screen, and 3) a confirmation cohort of 102 patients referred for clinical confirmatory testing instigated by positive DTC results from third party analysis of raw data.

Results
In the indication-based cohort 12,846 patients had a mutation in any HCS-associated gene: 4,733 (37%) were in BRCA1/2, of which 12% were one of the 3 AJ founder mutations. Ethnicity impacted AJ founder mutation frequency: 81% of AJ patients with any BRCA1/2 mutation had one of the 3 founder mutations, but only 6% of non-AJ patients. Overall clinical false-negative rate for the 3 AJ founder mutations in BRCA1/2 carriers was 88%; rates were 19% and 94% among AJ and non-AJ individuals, respectively. In the screening cohort, where 2.6% were AJ, 40 patients had a P/LP mutation in BRCA1/2; 12.5% were an AJ founder mutation. The clinical false-negative rate of 88.5% for any BRCA1/2 mutations in the screening cohort is similar to the indication-based cohort. Finally, in the confirmation cohort, among patients told of a positive DTC screening result, our analyses indicated 50% (52/102) were analytic false positives.

Conclusions
This study highlights the limitations of screening restricted to a few of the many genetic variants associated with HBOC risk. We found a greater rate of non-founder BRCA1/2 mutations in AJ patients than previously reported, and found a concerning rate of clinical false negatives with screening limited to the AJ founder variants. Although increasing access to genetic information is vital, the limitations of current DTC genetic screening, despite warnings from the FDA, may not be well understood by consumers and should be used with caution. Patients screened for HBOC on a platform limited to the AJ founder variants and supplemented by analysis of raw genotyping data, should receive confirmatory testing, regardless of having either a positive or negative result, a recommendation which the DTC companies and third party analysts of raw data ostensibly support. These results suggest that all HCS screening should include the support of a qualified clinician to assess the potential limitations and implement appropriate clinical management recommendations for patients and their family members.
Analysis of hereditary cancer syndromes by using a panel of genes: Novel and multiple pathogenic mutations

BACKGROUND
Hereditary cancer predisposition syndromes are believed to be responsible for approximately 5-10% of all diagnosed cancer cases. In the past, single genes analysis of certain high risk genes was used for the determination of the genetic cause of cancer heritability in certain families. The selection of genes was mainly based on the family history of the individuals analyzed and included only highly associated genes (e.g. the BRCA1 and BRCA2 genes for families with breast cancer history. Nowadays though, the application of Next Generation Sequencing (NGS) technology has facilitated multigene panel analysis and is widely used in clinical practice, for the identification of individuals with cancer predisposition gene mutations.

AIM
The aim of this study was to investigate the extent and nature of mutations in 36 genes implicated in hereditary cancer predisposition in individuals referred for testing in our lab.

MATERIALS & METHODS
In total, 1197 individuals were referred for testing in our lab in the past four years from Greece, Romania and Turkey. The analysis of genes involved in hereditary cancer predisposition was performed using two NGS approaches. The first 451 individuals were analyzed using an amplicon based sequencing method (26 gene panel), while the following 746 individuals were analyzed using a capture based method (33 gene panel). Genomic DNA was enriched for targeted regions of 36 genes involved in hereditary predisposition to cancer included in both versions of the panel (APC, BMPR1A, BRCA1, BRCA2, CDH1, CDK4, CDKN2A, EPCAM, MEN1, MLH1, MSH2, MSH6, MUTYH, PALB2, PMS2, PTEN, RET, SMAD4, STK11, TP53, VHL, ATM, BRI1, CHEK2, NBN, RAD51C, RAD51D, BARD1, BLM, CHEK1, ABRAXAS1 (FAM175A), MRE11 (MRE11A), NF1, RAD50, RAD51B, XRCC2). Sequencing was carried out using the Illumina NGS technology. Reads were aligned to the reference sequence (GRCh37), and sequence changes were identified and interpreted in the context of a single clinically relevant transcript. The presence of large genomic rearrangements was investigated by computational analysis of NGS results and the use of MLPA technology.

RESULTS
In total, a pathogenic mutation was identified in 259 of the 1197 individuals (21.6%) analyzed while a VUS was identified in 35.7% of the cases. Clinically significant mutations were identified in 29 of the genes analyzed. Concerning the mutation distribution among individuals with positive findings, 44.7% of them were located in BRCA1/2 genes whereas 20.9%, 19.9%, and 14.5% in high, moderate and low risk genes respectively. In addition to BRCA1 and BRCA2 genes other highly mutated genes were CHEK2 (10.6%), PALB2 (7.1%), MUTYH (7.1%) and ATM (4.3%). Of note is that 25 of the 259 positive individuals (9.7%) carried clinically significant mutations in two different genes and 5.8% had a large genomic rearrangement (LGR).

CONCLUSIONS
Our results support the clinical significance of analysis of a panel of genes involved in hereditary cancer predisposition. In our cohort, analysis of this panel allowed for the identification of 8.3% additional pathogenic variants in moderate/low risk genes,
enabling personalized management of these individuals.
Analyzing the clinical actionability of germline CYP2D6 polymorphism in Chinese breast cancer population

Liang Huang1 and Ayong Cao1. 1Fudan University Shanghai Cancer Center/Cancer Institute, Shanghai, China.

Background: Tamoxifen is effective for endocrine-responsive breast cancer as adjuvant therapy. CYP2D6 enzyme metabolizes tamoxifen to clinically active metabolites, while CYP2D6 polymorphisms may adversely affect tamoxifen efficacy by some retrospective clinical evidence. This study was carried out to estimate genotype frequencies of common variants of CYP2D6 in Chinese population. The relationship between prescription of selective estrogen receptor modulators (SERMs) and CYP2D6 polymorphism was also analyzed.

Methods: This was a retrospective research of early-stage patients who underwent surgical treatment at Fudan University Shanghai Cancer Center with ER+ and/or PR+ breast cancer. Genomic DNA was extracted from peripheral blood, which was used for genotyping CYP2D6*10 (C100T) single-nucleotide polymorphisms by polymerase chain reaction-based methods.

Results: A total of 312 patients with primary breast cancer were identified. More than 90.0% patients were in premenopausal status. The allele frequency of CYP2D6*10 in the Chinese population was 54.3%. The genotype frequencies of CYP2D6*10 were 20.5%, 50.3%, 29.2%, for wild-type, heterozygous and homozygous type respectively. We also found this SNP had no significant correlation with clinical characteristics. 145 patients were continuing endocrine treatment in first 5 years. 34.5% patients received CYP2D6 polymorphism test before the prescription of SERMs. The results significantly effected the choice of SERMs. Only 6.2% homozygous type patients took tamoxifen, 45.5% heterozygous patients chose tamoxifen, while 75.0% for wild type. 65.5% patients received CYP2D6 polymorphism test during the treatment of tamoxifen. 63.9% homozygous type patients switched to Toremifene, while 18.9% heterozygous patients changed the endocrine treatment.

Conclusions: The results showed that the frequency of CYP2D6*10 allele was high and nearly 30% Chinese breast cancer population were intermediate metabolizer for tamoxifen. The cyp2d6 polymorphism would influence prescription of SERM in premenopausal breast cancer patients. Patients with homozygous types should take other endocrine treatment instead of tamoxifen, which need more evidence of prospective clinical trials.
Genetic and hereditary factors in breast cancer: Experience in a mastology service on analysis of genetic tests in high risk women

Sabrina RP Chagas1,2, Maria de Rosario S Pineres1, Carlos Ricardo Chagas1 and Roberto JS Vieira1. 1PUC, Rio de Janeiro, Brazil and 2Mamarj, Rio de Janeiro, Brazil.

Background: Breast cancer is the most prevalent cancer in women in Brazil. The estimate by 2018 is 59,700 new cases. Of these, 10 to 15% are hereditary, caused by mutations in susceptibility genes that increase the risk of disease onset. These types of mutations can occur in several genes, each associated with different risks of developing the pathology. In hereditary breast-ovarian syndrome, the most frequently altered genes are BRCA1 and BRCA2. Mutations of these genes are associated with a 70-85% risk of developing breast cancer during life, but we know that there are other types of genetic alterations at risk of developing breast, ovarian, or other cancers - many are of uncertain significance and others, less known, appear to have high pathogenic potential. Thus, individuals identified with hereditary risk for developing breast or ovarian cancer should have intensive follow-up and genetic counseling.

Materials and methods: A retrospective study was carried out between 2015 and 2018. The charts of each of the patients submitted to genetic counseling with a total of fifteen women were analyzed. Eleven of these, performed genetic tests to evaluate mutations in BRCA1 and 2, and four patients extended panels. Subsequently, a statistical analysis of the data was performed and the results were analyzed thanks to the informed consent that the patients signed.

Results: Among the fifteen cases the age ranged from 27-68 years. Fifteen patients were analyzed, twelve with diagnosis of breast cancer and three without. In the eleven women who tested for BRCA1/2, 27% had mutations for these types of genes and three pathogenic variants of the genes. In the four who did the extended test, three had mutations in six types of genes, two with mutations of uncertain significance(VUS) and one pathogenic variant of the BLM gene. The indications for the exams were: 1)breast cancer patients: five cases with triple negative carcinomas and age less than 60 years-41.66%; 2)four with family history-33.33%; 3)three only by age-25%. In those without breast cancer the indications were family history. The majority of cases were requested for triple negative neoplasia, in which two cases presented mutation(40%) and three cases without mutation(60%), the two mutations in the BRCA1 and BRCA2 genes, one in each of them and none in VUS . In the four cases with a family history, two had mutations and two did not(50%) - two in BRCA 2 and one in VUS. In the three cases without cancer was found mutation in only one of them and with important family history was found mutation in one case(BRCA2).

Conclusions: Mutations in BRCA1/2 genes are associated with susceptibility to develop breast-ovarian cancer. Currently these mutations are responsible for only a minority of familial cases and we also find variants of uncertain and pathogenic behavior. Intensive research to identify other types of genetic mutations that could be responsible for a significant percentage of breast cancer in BRCA1/2 negative families, as well as assessing their importance, appear to be necessary. As already published by other authors, although our casuistry is small, we also call attention to the presence of mutations in young patients with triple negative breast carcinomas.
Identifying germline APOBEC3B deletion using hereditary cancer panel in Korean patients with operable breast cancer

Se Hyun Kim¹, Koung Jin Suh¹, Yu Jung Kim¹, Soomin Ahn¹, So Yeon Park¹, Su Min Chae¹, Eunyoung Kang¹, Eun-Kyu Kim¹, In Ah Kim¹ and Jee Hyun Kim¹. ¹Seoul National University Bundang Hospital, Seongnam, Korea.

Background: APOBEC3B is a cytosine deaminase implicated in host immune defense to virus and mutagenesis in cancer. Germline APOBEC3B deletion is known as risk factors for breast cancer with hypermutation and immune activation from previous database-based studies. This study was aimed to evaluate the incidence of germline APOBEC3B deletion in Korean patients with operable breast cancer.

Method: The copy number variants of germline APOBEC3B deletion was analyzed from leukocyte DNA of 103 breast cancer patients whose bloods were collected in 2009 for pharmacogenomic study at Seoul National University Bundang Hospital. Hybrid-capture based next-generation sequencing panel targeting 53 hereditary cancer genes were used. We also measured tumor infiltrating lymphocytes (TILs) and programmed cell death-ligand 1 (PD-L1) expression in tumor or immune cell with a rabbit monoclonal antibody (E1L3N).

Results: Median age of breast cancer diagnosis was 46 (25-72). In APOBEC3B deletion analysis, 10 (9.7%), 36 (35.0%), and 57 (55.3%) patients were identified as two-copy deletion (A3B₅del/del), one-one copy deletion (A3B₅del/wt) and no deletion (A3B₅wt/wt), respectively. In non-APOBEC3B analysis, 9 (8.7%) patients were identified as pathogenic variant: RAD51D(n=1), GJB2(n=1), BRCA1 (n=1), BRCA2 (n=2), ATM(n=1), USH2A(n=1), RET(n=1), BARD1(n=1). We observed no significant association between germline APOBEC3B deletion with any clinicopathologic features of breast cancer such as age, family history of cancer, and bilateral breast cancer. Triple-negative subtype was associated with A3Bwt/wt Tumors (35.1% in A3Bwt/wt vs. 5.6% in A3Bdel/wt vs20% in A3Bdel/del; P=0.018). After a median follow-up time of 92.8 months, APOBEC3B deletion was not predictive of recurrence or survival. In patients with sufficient tumor samples for the assessment of TIL (n=63) and PD-1 (n=71), A3Bdel/del tumor was associated with higher TILs (>10%) than other tumor types (6/7 patients in A3Bdel/del vs. 13/24 in A3Bdel/wt vs. 15/32 in A3Bwt/wt; Fisher’s exact test in A3Bdel/del, P=0.029).

Germline APOBEC3B deletion and TILs (n=63)

<table>
<thead>
<tr>

</tbody>
</table>

However, PD-L1 expression was not associated with APOBEC3B deletion status (1/7 patients >1% PD-L1 in A3Bdel/del vs. 4/26 in A3Bdel/wt vs. 8/38 in A3Bwt/wt; P=0.901).

Conclusion: We identified germline APOBEC3B deletion in 9.7% of Korean patients with operable breast cancer. The relationship between A3Bdel/del tumor and high TILs suggests that these tumors might be potential candidates for future immunotherapy.
The landscape of somatic genetic alterations in breast cancers from CHEK2 germline mutation carriers

Rahul Kumar¹, Xin Pei¹, Pier Selenica¹, Hannah Y Wen¹, Simon Powell¹, Mark Robson¹, Nadeem Riaz¹, Jorge S Reis-Filho¹, Britta Weigelt¹ and Diana Mandelker¹. ¹Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Checkpoint kinase 2 (CHEK2) is a tumor suppressor gene, which regulates cell cycle in response to DNA damage response. Selected CHEK2 germline mutations have been shown to confer an increased risk of breast cancer development. Multiple founder mutations in CHEK2 have been identified, and meta analyses have shown that CHEK2 truncating variants confer a higher breast cancer risk than missense variants. Here, we assessed the phenotype and repertoire of genetic alterations of breast cancers from 33 patients with CHEK2 pathogenic germline variants.

Materials and methods: We performed targeted capture massively parallel sequencing (≥410 genes) of tumor and normal samples from 13 patients with CHEK2 pathogenic germline variants, and retrieved whole exome sequencing (WES) data (BAM files) of tumor and normal samples from 20 patients with CHEK2 germline pathogenic variants included in the TCGA breast cancer study. In addition, we retrieved WES data of BRCA1, BRCA2 and ATM associated breast cancers from TCGA and Weigelt et al. (JNCI 2018). Somatic mutations, copy number alterations, mutational signatures and large-scale transitions (LSTs) were defined using state-of-the-art bioinformatics algorithms.

Results: Of the 33 CHEK2-associated breast cancers included in this study, 21 had missense and 12 had loss-of-function (LoF) germline mutations, and 81% were ER-positive and 12% HER2-positive. CHEK2-associated breast cancers statistically significantly less frequently displayed an ER-negative/HER2-negative phenotype (0%) than BRCA1- (80%) or BRCA2-associated (33%) breast cancers (BRCA1, p<0.0001 for both comparisons), but were similar to ATM-associated breast cancers. Biallelic inactivation of CHEK2 through loss of heterozygosity (LOH) of the wild-type allele was present in 17 of 33 samples (52%). LOH of the CHEK2 wild-type allele was significantly more frequent in tumors with LOF mutations than in those with missense mutations (78% vs 36%, respectively; p=0.0394). PIK3CA (36%) and GATA3 (33%) were the two most recurrently mutated genes in these samples. TP53 somatic mutations were detected in five cases, four of which harbored missense CHEK2 germline mutations. Unlike BRCA1- and BRCA2-associated breast cancers, but akin to ATM-associated breast cancers, CHEK2-associated breast cancers lacked the mutational signature associated with homologous recombination (HR) DNA repair defects (i.e. signature 3) and only five cases displayed high LST scores.

Conclusion: CHEK2-associated breast cancers are phenotypically and genetically distinct from BRCA1- and BRCA2-associated breast cancers, but similar to ATM-associated breast cancers. Akin to ATM-associated breast cancers, CHEK2-associated breast cancers are preferentially ER-positive, lack genomics features consistent with defective HR, and have a repertoire of somatic genetic alterations similar to those of non-BRCA1/2 ER-positive breast cancers. Our results suggest that either CHEK2 germline mutations contribute to an increased risk of breast cancer independently of the HR DNA repair defects or that the mutational signatures caused by CHEK2 pathogenic germline mutations differ from those caused by pathogenic germline mutations affecting bona fide HR-related genes (e.g. BRCA1, BRCA2 and PALB2).
Identifying ERBB-2 activating mutations (mts) in HER2 negative tumors for clinical trials – Impact of institute-wide genomic testing and trial matching on trial enrollment in clinical practice

Pedro Exman¹, Ana Garrido-Castro¹, Melissa E Hughes¹, Rachel A Freedman¹, Cynthia Ma², Ron Bose³, Ethan Cerami¹, Nikhil Wagle¹, Romualdo Barroso-Sousa¹, Catherine D Fitz¹, Neal I Lindeman³, Laura MacConaill², Brittany L Bychkovsky¹, Maxwell R Lloyd¹, Colin R Mackichan¹, Priti Kumari⁰, Sara M Tolaney¹, Ian E Krop¹, Eric P Winer¹, Deborah A Dillon¹,3 and Nancy U Lin¹.

¹Dana Farber Cancer Institute, Boston, MA; ²Washington University School of Medicine in St Louis, St. Louis, MO and ³Brigham and Women’s Hospital, Boston, MA.

Introduction
Tailored treatment trials with biomarker-driven hypotheses are becoming an important strategy in drug development. Umbrella, basket and enrichment trials with eligibility predicated upon results of tumor sequencing are increasingly common. Several institutional and commercial genomic assays have been developed. However, the value of broad-based testing in recruiting patients (pts) to molecular-based clinical trials designed for small subgroups has not been fully evaluated and has been challenging to assess in a real-world setting. We evaluated the likelihood of trial enrollment based upon an institute-wide genomic test.

Methods
Since 2013, all pts with metastatic breast cancer (MBC) seen at least once at Dana-Farber Cancer Institute have been offered the option of tumor sequencing using multiplexed copy number variation (CNV) and mts detection across the full coding regions of a total of 447 cancer genes and 191 regions across 60 genes for rearrangement detection (Oncopanel; OP). For our primary analysis, we selected the ongoing multi-center phase II trial (NCT01670877) activated at our site on Sep 30, 2013, evaluating neratinib in ERBB-2 mutated pts, as the study provided a clear delineation of eligible mts, and timing of slot availability was retrievable retrospectively over an extended time frame. Our primary aim was to describe the proportion of pts with a qualifying ERBB-2 mt detected by OP who enrolled on the selected trial. Secondary objectives included median time from OP result to trial registration and description of ERBB-2 mts spectrum within each subtype. Associations were calculated by Fisher’s test.

Results
We identified a total of 1,046 pts with HER-2 negative MBC and who had OP results between Sep 1, 2013 and Jun 1, 2017. A total of 43 pts (4.1%) were found to have ERBB-2 mts. Of these, 20 (1.9%) had activating eligible mts. The proportion of these pts who enrolled in the trial was 30% (6/20). Of the remaining 14 pts, 5 screen-failed and 2 were enrolled with known ERBB-2 mt through other testing modalities. Seven of 20 (35%) molecularly eligible pts were not approached (3 pts lost to follow-up, 3 enrolled in other clinical trials and 1 pt chose standard treatment). The median time from OP result to trial enrollment was 85 days (34-554). A significantly higher frequency of ERBB2 activating mts was found in ER+ compared to ER- primary tumors (2.5% vs. 0.3%, p =0.036), and in lobular tumors compared with ductal (5.5% vs. 1.25%, p=0.003). Frequency of eligible mts in primary tumors were similar to metastatic site (1.9% and 1.8%, respectively p=1.0)

Discussion
In this cohort, activating ERBB-2 mts were present in 20 of 1046 (1.9%) pts tested. Although over half of pts with mts on OP testing were approached for NCT01670877, only 0.5% of the total tested population were enrolled (6/1046). Our data illustrate the substantial challenges in screening and enrolling to trials of rare subsets, even within a large academic institution, and point to the need for creative and novel approaches to leverage pts and community- and academic-based providers to more effectively support the success of such studies.
PIK3CA mutations in breast tumor specimens in a cohort (n=791) of a multicentric study and associations to known prognostic factors and survival data

Kristin Reinhardt¹, Christoph Thomssen¹, Hanf Volker², Lantzsch Tilmann³, Uleer Christoph⁴, Peschel Susanne⁵, John Jutta⁶, Buchmann Joerg⁷, Weigert Edith⁸, Bürrig Karl-Friedrich⁹, Kantelhardt Eva Johanna¹ and Vetter Martina¹. ¹Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany; ²Klinikum Fürth, Fürth, Germany; ³St. Elisabeth & St Barbara Hospital, Halle (Saale), Germany; ⁴Medical Office Uleer, Hildesheim, Germany; ⁵St. Bernward Hospital, Hildesheim, Germany; ⁶Klinikum Hildesheim, Hildesheim, Germany; ⁷Institute of Pathology, Hospital Martha-Maria, Halle (Saale), Germany; ⁸Institute of Pathology, Klinikum Fürth, Fürth, Germany and ⁹Institute of Pathology, Hildesheim, Germany.

Introduction:
The PI3K/AKT/mTOR signalling pathway plays an important role in cellular processes like proliferation, apoptosis, survival and adhesion of tumor cells. It is one of the most deregulated pathways in cancer. In up to 30% of breast cancers, dysregulation of this pathway is reported, resulting from mutations in the PIK3CA gene that encodes the catalytic subunit (p110α). Hotspots of mutations, comprising 86% of all observed PIK3CA-mutations, were described in exon 9 (helical domain, E542K, G > A; E545K, G > A) and exon 20 (kinase domain, H1047R, A > G). Prevalence and the prognostic impact of the PIK3CA mutations as well as the predictive value with regard to endocrine therapy are controversially discussed.

In this study we describe the prevalence of the three most frequent PIK3CA mutations in a consecutive cohort of breast cancer patients and its association to tumor characteristics, to known prognostic factors and survival data.

Methods:
The cohort consists of 1,047 patients who were newly diagnosed for non-metastatic breast cancer in one of 6 German breast centres from 2009 to 2011 and who were registered within the prospective PIA-study (Prognostic assessment in routine Application, NCT 01592825). DNA of 806 fresh frozen tumors were available for analysis by qPCR (exon 9: C 763 and C760; exon 20: C 775).

Associations between the PIK3CA mutation status and clinical, pathological parameters were evaluated using binary logistic regression model. Survival probabilities were estimated by Kaplan-Meier-method, Log-Rank-Test and Breslow-Test. Recurrence free interval (RFI) was defined according to STEEP criteria.

Results:
Mutation status for the three most common PIK3CA mutations was available for 791 tumors. The mutation rate was 29.2%. Only two tumors harbored two mutations (C 765, C 763). Tumors with a PIK3CA mutation were significantly more frequent in HR positive tumors (32%; p=0.001), in HER2 negative tumors (31%, p=0.010) and in tumors with low or intermediate histological grade (39%; 32% resp., each pTumors with a PIK3CA mutation showed a slightly better recurrence-free interval (93.6%, CI 93.2-94.01 vs. 90.3%, CI 89.9-90.7). We found a prognostic impact on RFI after 5 y F/U in patients with HR-negative tumors (93% vs 71%) and those with TNBC (100% vs. 70%).

Conclusion:
PIK3CA mutations occur frequently in breast cancer tumors. We found a prognostic impact only in patients with HR-negative and TNBC tumors.

This data adds important information to the heterogeneous results of other previously published patient cohorts. In summary in our study, tumors that harbour a mutation of the PIK3CA-gene, were associated to prognostically more favorable factors and a better recurrence-free intervall.
The mutational profile of inflammatory breast cancer reveals a higher mutational burden leading to MAPK activation and chromatin remodeling

Steven Van Laere1,2, Pascal Finetti3, Charlotte Rypens1,2, Charlotte Billet1, Daniel Birnbaum3, Peter Vermeulen1,2, Patrice Viens3, Luc Dirix1 and Francois Bertucci3. 1University of Antwerp, Wilrijk, Belgium; 2GZA Hospitals Sint-Augustinus, Wilrijk, Belgium and 3Institut Paoli-Calmettes, Marseille, France.

Introduction. Inflammatory breast cancer (IBC) is an aggressive form of locally advanced breast cancer with increased metastatic potential. In the past, we have identified a gene expression profile that characterizes IBC, suggesting that a specific molecular biology underpins this devastating disease. Here, we explore the hypothesis that the molecular portrait of IBC is a reflection of underlying genomic alterations.

Materials and Methods. Mutation and copy number variation (CNV) profiles for 663 genes were assembled from 2,352 publicly available primary tumor samples (subtype distribution: 1,520 HR+, 355 HER2+, 414 TNBC and 190 unassigned) including 127 profiles from patients with IBC. Gene-wise differences in the frequency of genomic aberrations between patients with and without IBC, stratified per subtype, were investigated using Chi-square testing with adjustment for multiple comparisons. Genomic perturbation differences of pathways and processes, represented by KEGG or Gene Ontology gene sets, were evaluated by collapsing mutation and CNV profiles across all genes associated with the respective gene sets. Finally, mutational signature (MS) profiles were calculated and compared between patients with and without IBC.

Results. Seventy-six genes showed evidence of more extensive genomic alterations in samples from patients with IBC as compared to those without IBC (i.e. false discovery rate < 10%), whereas only 3 genes reveal the opposite pattern. Genes mutated in more than 15% (range 16.2% - 63.5%) of the IBC samples include: AXIN1, ERBB2, ERBB3, CBL, CTNNB1, CYP2D6, FGFR1, INSR, KIT, KMT2A, LRP1B, MYC, PBRM1, SACS, SMAD4, TP53 and ZNF217. Analysis of MS profiles revealed differences for signature 1 (i.e. age-related deamination of 5-methylcytosine), 2 (i.e. APOBEC3 activity), 3 (i.e. defective homologous recombination), 11 (i.e. alkylating agents), 20 (i.e. DNA mismatch repair) and 24 (i.e. aflatoxin), of which MS 11 and 24 are more active in IBC. When evaluating the same panel of genes in TNBC only, 28 genes were retained, suggesting data are confounded by the subtype distribution. Pathway analysis revealed genomic perturbation of MAPK signaling and chromatin organizational processes in respectively 55% and 74% of TN IBCs.

Discussion. These data suggest that IBC is characterized by an extensive mutational burden that results, amongst others in the activation of MAPK signaling as well as chromatin remodeling. The analysis of MS profiles does not provide a clear biological explanation for the increased frequency of genomic alterations in IBC, with APOBEC3 activity, defective homologous recombination, defective DNA mismatch repair and age-related deamination of 5-methylcytosine all being more prominent in nIBC samples. Notably, the lower frequency of age-related C>T transitions is in line with younger age at diagnosis typical for patients with IBC.
Spatial heterogeneity revealed by genomic profiles comparing 60 matched primary breast tumors and metastatic lymph nodes

Ning Liao¹, GuoChun Zhang¹, Yulei Wang¹, Liping Guo¹, Li Cao¹, Chongyang Ren¹, Lingzhu Wen¹, Kai Li¹, Minghan Jia¹, Shaokun Chuai² and Xiaoqing Chen¹. ¹Cancer Center Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China and ²Burning Rock Biotech, Guangzhou, China.

Background: Genomic profiling in primary breast tumors has been extensively performed and reveals the heterogeneous complexity in mutational landscape of the disease. However, little is known about differential mutation spectrums in synchronous breast tumors and matched metastasis in axillary lymph nodes. To characterize the spatial heterogeneity and identify potential biological mechanisms involved in the lymph node metastasis, we determined the genomic mutational profiles in synchronous primary lesion (PL) and metastatic lymph nodes (MLN) by using ultra-deep targeted sequencing.

Methods: Targeted deep sequencing was performed using a panel including 520 cancer-related genes and spanning 1.6MB of human genome. The mutational profiles were compared between the matched PL and MLN samples from 60 of treatment-naïve patients with invasive breast cancer and axillary lymph node metastasis. KEGG enrichment analysis was further performed between specific and shared mutations in either PL or MLN samples. The relationship between spatial heterogeneity and clinical characteristics was also explored.

Results: The cohort had a median age of 45 (ranging from 28-67), with a majority (86.7%) of them diagnosed with infiltrating ductal carcinoma. In this 60-paired cohort, 961 genomic aberrations were identified in 242 genes, including 405 single nucleotide variants (SNVs), 66 insertions or deletions (INDELs), 482 copy-number amplifications (CNAs), and 8 translocations. Although 584 (60.8%) events were shared in PL and MLN samples, 226 (23.5%) mutations spanning 51 genes and 151 (15.7%) mutations involving 46 genes were specific PL and MLN samples, respectively. In addition, 7 of patients (11.7%), all of whom are hormonal receptor (HR) positive, harbored completely similar mutation spectrum between PL and MLN. Twenty-one patients (35%) had PL specific mutations, but had no MLN specific mutations. In contrast, 6 patients (10%) only had MLN specific mutations and the remaining 26 patients (43.3%) had both PL and MLN specific mutations. Interestingly, the Ki67-based proliferation index in 7 of patients with completely similar mutation spectrum were significantly lower than other patients with differential mutational landscapes between PL and MLN (p=0.019). Furthermore, KEGG pathway enrichment analysis revealed that deregulation in PI3K/AKT and Ras signaling pathway were enriched in both PL and MLN samples. More importantly, we found that aberrant activation of Proteoglycans pathway and JAK-STAT signaling, as well as aberrant HIF-1 pathway, was specifically occurred in the MLN samples, suggesting crucial roles for these signaling pathways in the involvement of lymph node metastasis.

Conclusions: Our study revealed genomic heterogeneity between primary tumors and lymph nodes, and identified mutations as well as pathways that are potentially relevant to lymph node metastasis, emphasizing that such spatial heterogeneity may contribute to the evolution of the disease and result in differential responses of subsequent treatments. This study was supported by funding from National Natural Science Foundation of China (Grant No. 81602645) and Guangdong Provincial Natural Science Foundation (Grant No. 2016A030313768).
Study of the mutational landscape of normal and pregnant breast to predict pregnancy-associated breast cancer risk

Biancastella Cereser¹, Neha Tabassum¹, Philip Carter¹, Lisa Del Bel Belluz¹ and Justin Stebbing¹. ¹Imperial College London, London, United Kingdom.

Background: Amongst the various risk factors for breast cancer (BC), the molecular basis which may explain the correlation between age at first full-term and breast cancer risks is still understudied. Epidemiology studies indicate that an early first full-term pregnancy (before 25 years of age) confers a significant level of protection towards the development of post-menopausal BC compared to the risk in nulliparous or late-parous women. On the other hand, any pregnancy relates to a higher risk in developing cancer during or within one year of pregnancy (pregnancy-associated breast cancer, PABC). Thus, the relation between age of pregnancy and breast cancer risk may be too difficult to explain using only epidemiology data.

Aims of the study: With our research study, we aim to study a cohort of 60 normal breast samples of nulliparous and age-matched early- and late-parous women collected from Komen Tissue Bank, University of Indiana, and to create for the first time a mathematical model of cell clone expansion in the normal breast growth. This will allow us to determine how the rates of both cancer drivers, passenger mutations and genetic variations are affected by pregnancy. We then aim to translate this in cancer tissues, and to determine how the rate of the same mutations in both pregnancy and non pregnancy-associated cancers (post-menopausal). At the same time, we intend to create a mouse model which will be used to further validate our model, where driver mutations will be induced in the mammary epithelium of pregnant mice of different ages. This will allow us to test our model of growth of a mutated clone in a pregnancy environment, and to determine what are the molecular changes in the pregnant mammary gland which can trigger a different BC risk in the early-parous cohort.

Results: To examine the mutational landscape in the normal parous and nulliparous women, we extracted DNA from laser-capture microdissected epithelium and the stroma, the latter of which will be used to eliminate germ line mutations. We are currently analysing the results from Whole Genome Sequencing at 30x 100pe on a MGISEQ2000 platform on a first set of samples (two nulliparous samples and two age-matched parous samples from both early and late pregnancy). Our procedure for processing and analysis of this data follows the Broad Institute’s “GATK Best Practice Guidelines” for use of next generation sequencing (NGS) data. Based on the collected data, we plan to continue with targeted sequencing or whole genome sequencing on the remaining samples.

Conclusions: Our study will provide novel information on which areas of the genome are mostly mutated or altered in the normal breast, and will indicate how mutated cells, including mutations in driver genes for breast cancer, and genetic alterations change in the contest of pregnancy. With the mathematical model of clone growth/extinction, we intend to explain how different ages of pregnancy can significantly alter the clone composition in the normal breast and result in a different probability of developing breast cancer.
High-throughput barcode screening elucidates the functional characteristics and mutual relevance of \textit{PIK3CA} and \textit{PIK3R1} somatic mutations in Chinese patients with breast cancer

Li Chen\(^1\), Liu Yang\(^1\), Xin Hu\(^2\) and Zhiming Shao\(^{1,2}\). \(^1\)Fudan University Shanghai Cancer Center, Shanghai, China and \(^2\)Key Laboratory of Breast Cancer in Shanghai, Shanghai, China.

\textbf{Background}

Deregulation of the phosphoinositide 3-kinase (PI3K) signaling pathway is essential to malignant cellular processes of breast cancer, including proliferation and drug response. Oncogenic somatic mutations of the PI3K pathway are pervasive in breast cancer. However, identification of impactful mutations and determination of their relevance to major components of this pathway remains difficult. This study was conducted to identify the landscape of somatic mutations in the PI3K pathway in a Chinese population. Notably, we developed a recombination-based mutation barcoding (ReMB) library which enables a high-throughput mutation-phenotype screens for vulnerable mutations that contribute to the cancer development and drug resistance.

\textbf{Methods}

We collected 149 breast cancer specimens in a Chinese population and performed Ion Torrent Amplicon Sequencing for the key genes in PI3K/AKT pathway: \textit{PIK3CA}, \textit{PIK3R1}, \textit{AKT1}, \textit{AKT2}, \textit{AKT3}, \textit{PTEN}, \textit{PDK1} at 1000× coverage. To discriminate between 'driver' and 'passenger' mutations, we developed a recombination-based mutation barcoding (ReMB) library that contained the novel identified mutations and that reported in TCGA and COSMIC databases in \textit{PIK3CA} and \textit{PIK3R1} genes, each mutation tagging with a specific barcode to identify their potential oncogenic and drug-resistant characteristics. The unique barcode representing each mutation was detected using Illumina Miseq sequencing following proliferation and drug response selection (doxorubicin and BKM-120) assays to screen the functional mutations.

\textbf{Results}

We identified that mutations in \textit{PIK3CA} (44\%), \textit{PIK3R1} (17\%), \textit{AKT3} (15\%) and \textit{PTEN} (12\%) were prevalent and diverse in Chinese patients with a high proportion of tumours harboring multiple mutations, especially \textit{PIK3CA} plus \textit{PIK3R1} mutations (9.0\%). With ReMB screening, we found 11 non-synonymous impactful mutations in \textit{PIK3CA}; these included eight proliferation-driving mutations, nine doxorubicin-resistant mutations, and eight BKM120-resistant mutations. The highest-ranking \textit{PIK3CA} mutations include the deleterious mutations E542K, E545K and H1047R/L as well as mutations of unknown significance, including E39K, N345I, E453K, and G1049R. We also identified six non-synonymous impactful mutations in \textit{PIK3R1}, including five proliferation-driving mutations, six doxorubicin-resistant mutations, and five BKM120-resistant mutations. The \textit{PIK3R1} impactful mutations include E160D, Q329L, N564D and K674R. Most impactful mutations in \textit{PIK3CA} and \textit{PIK3R1} occurred at residues lying at the interfaces between p110 and p85, or between the functional domains within p110. These \textit{PIK3CA} and \textit{PIK3R1} impactful mutations exhibit a mutually exclusive pattern, leading to oncogenesis and hyperactivity of PI3K pathway. Additionally, impactful mutations in \textit{PIK3CA} are tightly associated with hormone receptor positivity.

\textbf{Conclusion}

This study identified the landscape of somatic mutations in the PI3K pathway in Chinese breast cancer patients. A novel developed ReMB screening platform allows the rapid identification of impactful \textit{PIK3CA} and \textit{PIK3R1} mutations in breast cancer and has important implications for PI3K-targeted therapy.
Genomic profiling of 304 treatment-naïve Chinese breast cancer patients: A comparison of Chinese and TCGA cohorts

Ning Liao¹, Guochun Zhang¹, Yulei Wang¹, Liping Guo¹, Li Cao¹, Zhou Zhang², Charles M Balch³ and Funda Meric-Bernstam⁴. ¹Cancer Center Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, Guangdong, China; ²Burning Rock Biotech, Guangzhou, Guangdong, China; ³University of Texas MD Anderson Cancer Center, Houston, TX and ⁴Institute of Personalized Cancer Therapeutics, University of Texas MD Anderson Cancer Center, Houston, TX.

**Background:** The complexity of BC at the clinical, morphological and molecular level has been well recognized. Molecular profiling, which reveals the intrinsic biology among subtypes, has significantly advanced the management of this disease. However, previous studies have provided very limited molecular data on Chinese breast cancer patients.

**Methods:** We performed targeted sequencing using a panel consisting of 36 BC related genes to interrogate the genomic landscape of 304 consecutive treatment-naïve Chinese BC patients and compared our results to the TCGA data set.

**Results:** Comparing to TCGA, our cohort had significantly fewer patients with triple negative breast cancer (8.2% vs 15.5% p=0.002). The most prominent genomic difference was our cohort had significantly higher $TP53$ mutation frequency in HR+/HER2- and HR+/HER2+ groups. The composition of $TP53$ mutations also differed significantly between two cohorts in HR+/HER2- group, with TCGA cohort having missense mutation as the predominant mutation; whereas, in our cohort, nonsense and frameshift mutations were predominant. We classified the most populated and diverse group of HR+/HER2- cancer into 4 subgroups based on molecular signature. The clinical significance of this proposed classification was confirmed by differences in overall survival using data from the TCGA.

**Conclusions:** We identified distinctive genomic patterns associated with Chinese breast cancer patients compared to TCGA data, suggesting the importance of mutation-based stratification according to ethnic status. To the best of our knowledge, this is one of the largest study of Chinese BC patients that interrogated the spectrum of mutational events and correlated these molecular signatures with clinical outcomes.

Comparing tumor mutation burden detection between whole exome and target enrichment sequencing among Taiwanese breast cancers

Chi-Cheng Huang¹ and Ching-Shui Huang². ¹Fu-Jen Catholic University Hospital, New Taipei, Taiwan and ²Cathay General Hospital, Taipei, Taiwan.

Purpose: The ability to detect tumor mutation burden (TMB) is increasingly demanding and has become a pre-requisite for breast cancer personalized therapies, especially for those interrogating immune-modulating agents. The optimized quantification method determining TMB, however, remains inconclusive, and the current study compared tumor mutation yields among Taiwanese breast cancers, either with whole exome or target enrichment sequencing.

Methods: Sporadic breast cancers were prospectively recruited. Target-enrichment sequencing was performed with Illumina Solexa™ technology with read length of 150 paired ends and was analyzed with Agilent SureCall™. There were 56 targets comprising 990 regions with a total regional size of 173,999 kbp. For whole exome sequencing, SureSelect™ Human All Exome V6r2 was adopted. The minimum coverage was set to 20 and the minimum alternative reads was set to 10 to enhance sequencing reliability. Samtools version 1.2 was utilized as variant caller for both whole exome and targeted sequencing. Novel and synonymous variants, as well as those located outside coding regions were removed. TMB was calculated as the number of somatic mutations per megabase (mb).

Results: A total of 61 and 52 Taiwanese breast cancers underwent target enrichment and whole exome sequencing, respectively. The number of somatic mutations ranged from 36 to 292 (median: 205), equivalent to 207~1678 (median: 1178) mutations/mb for targeted sequencing. On the other hand, there were 9947 to 10981 somatic mutations (median: 10727) when the whole exome was sequenced, resulting in TMB between 333 and 366 (median: 358). TMB for ER+/HER-, ER+/HER2+, ER-/HER2+, and ER-/HER2- was 1322 (n=31), 713 (n=11), 793 (n=10), and 1230 (n=9) for targeted sequencing and was 358 (n=29), 358 (n=12), 354 (n=5), and 357 (n=6) for whole exome sequencing. The most frequent nonsense mutations were NOTCH1 (S255*), RET (Q87*), KRAS (G57*), JAK3 (Y267*), and SMO (Y61*), while MAP2K1 (G148C), FNACA (G175V), BSG (H254P), ABL1 (T57P), and NOTCH1 (H416P) were the most common missense mutations.

Discussion and conclusions: High-throughput parallel massive sequencing can identify large numbers of variants, dependent both on the size of the sequenced regions and the variant caller algorithm utilized. Although Samtools identified more variants against reference than other methods, there should be no differential between whole exome and targeted sequencing. The number of somatic mutations, as well as the variability in TMB, was much higher in target enrichment approach than whole exome sequencing, highlighting that different TMB threshold should be established before wide clinical applications. Uneven distributions of “hotspot” mutation regions across genome as well as hundred-fold of sequencing length of whole exome versus targeted sequencing sequencing may contribute to such discrepancy.
Genomic profiling of multifocal breast cancer reveals inter-lesion heterogeneity

Soomin Ahn¹, Hyun Jeong Kim¹, Eunyoung Kang¹, Eun-Kyu Kim¹, Se Hyun Kim¹, Jee Hyun Kim¹, In Ah Kim¹ and So Yeon Park¹. ¹Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Introduction: Multifocal breast cancers are common, and tend to show more aggressive clinical features than unifocal breast cancers. While each foci of multifocal breast cancers with similar histology shares the same hormone and ERBB2 receptor status in most cases, substantial genomic differences among lesions have been reported. We aimed to investigate the potential genomic differences between multifocal breast cancer lesions.

Materials and methods: Twenty-one patients with multifocal breast cancer documented in the resection specimen were included. We selected two lesions with the same histology from each of these 21 patients. Capture-based targeted next generation sequencing was performed using a cancer gene panel consisting of 170 genes for single nucleotide variants (SNV) and small insertions/deletions (Indel), and copy number alterations.

Results: The most frequent mutation was TP53 (38.1%), followed by PIK3CA (28.6%). Pathogenic mutations (SNV and Indel) were detected in 13 of 21 patients, of whom 11 shared oncogenic variants in the two lesions. The remaining two patients had different mutation results in TP53 and PIK3CA, respectively. Genomic heterogeneity of copy number alteration was observed in 6 (28.6%) of 21 patients, including difference of FGFR1 status in two patients and difference of FGFR2 status in one patient.

Conclusion: Despite similar histologic features of multifocal tumors, genomic inter-lesion heterogeneity was identified in about one-fourth of patients. The spatial genomic heterogeneity in multifocal breast cancers needs to be considered in representative sampling and molecular tests for personalized medicine.
A small amount of primary breast cancer shows high tumor mutation burden that may benefit from immune checkpoint inhibitor therapy.

Jingshu Wang¹, Wei Chen², Zhimin Jiang¹, Xiangan Lin¹, Tao Qin¹, Xing Yang¹, Tianhao Liu¹, Hai Hu¹, Zhihua Li¹, Derong Xie¹, Herui Yao¹ and Erwei Song¹. ¹Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China and ²The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China.

Background: Targeted therapy using immune checkpoint inhibitors (ICIs) is a major breakthrough in cancer treatment in the last decade. ICIs like PD1 or PD-L1 antibodies have been shown to be quite effective in cancer like melanoma. However, in most other tumor types including breast cancer, the situation is not as optimistic. Only a small percentage of those patients respond to ICIs therapy. This highlights the importance of identifying biomarkers to predict which patients may benefit from such treatment. Tumor Mutation Burden (TMB) has been shown to be a sensitive marker for ICI treatment. This study is to investigate whether TMB could be used as a biomarker for breast cancer treatment.

Methods: We reviewed next generation sequencing studies of breast cancer. Two such studies with raw data provided were included in our analysis. One study entitled METABRIC performed targeted sequencing of 173 cancer-related genes in around 2500 primary breast cancer tissues. The other study was from TCGA breast cancer project, which performed Whole Exome Sequencing (WES) of around 1000 primary breast cancer samples. Mutation data were downloaded from public data deposit. The number of mutations per sample was calculated. TMB was calculated by divide the coverage in million base pair from that of the total mutation counts.

Results: In METABRIC study, 17272 mutations were identified in 2369 samples, with a median of 7 mutations per sample (95% CI: 6 ~ 7). The median TMB of METABRIC dataset was 5.8 SNVs/Mb (95% CI: 5 ~ 5.8). Totally 30 out 2369 (1.3%) samples had a TMB equal or larger than 20 SNVs/Mb. In another cohort from TCGA breast cancer study using WES technology, 90172 mutations were identified in 977 samples, with a median of 44 mutations per sample (95% CI: 39 ~ 50). The median TMB was 1 SNVs/Mb (95% CI: 0.9 ~ 1.1). Totally 13 out 977 (1.3%) samples had a TMB equal or larger than 20 SNVs/Mb.

Conclusions: Breast cancer shows middle to low mutation burden compared to other cancer types. Around 1.3% of breast cancer has quite high TMB of at least 20 SNVs/Mb, which may be qualified for immune checkpoint inhibitors therapy. Our study indicates that TMB may be incorporated as a standard test for late stage breast cancer patients in the clinical practice.

TZAP mutation leads to poor prognosis of patients with breast cancer

Jae-Ho Lee’. Keimyung University, Daegu, Korea.

The zinc finger protein ZBTB48 is a telomere-associated factor that has been renamed as telomeric zinc finger-associated protein (TZAP). It binds preferentially to long telomeres, competing with telomeric repeat factors 1 and 2. However, its expression in cancers has not been investigated. In the present study, we analyzed the TZAP mutation in 128 breast carcinomas (BCs). In addition, its association with telomere length was investigated. The TZAP mutation (c.1272G>A, L424L) was found in 7.8% (10/128) of the BCs and was associated with the N0 stage (p = 0.035). BCs with the TZAP mutation had longer telomeres than those without this mutation (2.62 ± 1.71 vs. 0.98 ± 0.37, p = 0.009). Telomere elongation was shown in 29.7% (38/128) of BCs and was significantly higher in luminal A and triple negative BCs (p < 0.001). Other characteristics were not associated with TZAP mutations and telomere length. Survival analysis showed that the TZAP mutation resulted in a poorer overall survival (52.8 vs. 87.3 months, \( \chi^2 = 4.37, P = 0.037 \)). However, telomeres did not have any prognostic value for BCs (\( P = 0.908 \)). These results suggest that the TZAP mutation is a possible prognostic marker in BC.
Limb-Bud-and-Heart (LBH), a novel WNT effector in promoting basal-like breast cancer

Karoline Briegel and Kilan Ashad-Bishop. 1University of Miami Miller School of Medicine, Miami, FL.

BACKGROUND: Clinically aggressive basal-like breast cancers (BLBC) disproportionately contribute to cancer deaths, but lack effective treatment options due to absence of expression of key therapeutic targets (i.e. ER, PR, HER2). New evidence suggests BLBC may originate from luminal breast epithelial cells through luminal-to-basal cell lineage conversion and dedifferentiation. However, the factors that reprogram cell fate and differentiation states during BLBC development remain poorly understood. Our laboratory has identified a novel WNT/β-Catenin target transcriptional regulator, Limb-Bud-and-Heart (LBH), and shown LBH is majorly over expressed in aggressive BLBC harboring WNT hyperactivation. We previously showed in genetic mouse models in vivo that LBH is a key mammary stem cell and basal cell lineage regulator essential for normal mammary gland development. Using crosses between MMTV-Wnt1 transgenic mice and conditional LBH knockout mice, we tested if LBH is a critical effector of WNT-driven baseloid breast cancer, and whether its inhibition may prevent and/or attenuate BLBC formation and progression.

RESULTS: In our in vivo mouse model, LBH inactivation in the basal mammary epithelium using a Keratin 14/K14-Cre deleter strain significantly attenuated MMTV-Wnt1-induced mammary gland hyperplasia and led to a delay in tumor onset. Surprisingly, tumor burden and tumor volumes were not changed, indicating that LBH is not required for WNT-driven tumorigenesis. However, LBH-deficient MMTV-Wnt1-transgenic tumors exhibited pronounced histopathological differences compared to LBH WT MMTV-Wnt1-transgenic tumors. Whereas MMTV-Wnt1+;K14CreLbh WT tumors were highly vascularized, disorganized, with mixed basal and luminal cell identity; tumors from MMTV-Wnt1+;K14CreLbh KO mice were more organized, differentiated, and predominantly luminal Keratin 8 positive. Since attenuation of mammary gland hyperplasia and tumor onset in this model suggests that LBH deficiency may negatively affect WNT-induced stem cell expansion, we next investigated the LBH effects on the tumor stem cell compartment. MMTV-Wnt1+;K14CreLbh KO mice were crossed with two different stem cell reporter lines: Lgr5-eGFP mice, which specifically mark WNT-responsive epithelial stem cells; and SHIP-GFP reporter mice, which mark activated, proliferating mammary stem cells but not quiescent or slow-cycling stem cells. These studies are ongoing and the latest findings will be discussed.

CONCLUSION: Our data indicate that LBH is an essential cell fate regulator downstream of oncogenic WNT signaling that maintains basal lineage identity in baseloid breast cancers. LBH inhibition may be a potential novel strategy to treat basal subtype triple negative breast cancer patients through differentiation therapy.
Immunomonitoring of triple negative breast cancer patients undergoing neoadjuvant therapy with durvalumab - Results from the prospectively randomized GeparNuevo trial

Chiara Massa1, Andreas Schneeweiss2, Thomas Kam3, Claus A Hanusch4, Jens-Uwe Blohmer5, Peter A Fasching6, Christian Jackisch7, Marion van Mackelenbergh8, Frederik Marmé2, Volkmar Müller9, Christian Schem10, Elmar Stickeler11, Jens Huober12, Karsten E Weber13, Michael Untch14, Carsten Denkert15, Sibylle Loibl13, Anja Mueller1, Katharina Biehl1 and Barbara Seliger1.
1Institute of Medical Immunology, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany; 2Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany; 3Klinik für Frauenheilkunde und Geburtshilfe, Universitätsklinikum, Frankfurt, Germany; 4Klinikum zum Roten Kreuz, München, Germany; 5Brustzentrum, Charité-Universitätsmedizin, Berlin, Germany; 6Brustzentrum, Universitätsklinikum, Erlangen, Germany; 7Sana Klinikum, Offenbach, Germany; 8Klinik für Gynäkologie und Geburtshilfe, Universitätsklinikum, Kiel, Germany; 9University Medical Center, Hamburg, Germany; 10Mammazentrum Hamburg am Krankenhaus Jerusalem, Hamburg, Germany; 11Uniklinik RWTH, Aachen, Germany; 12Universitätsfrauenklinik, Brustzentrum, Ulm, Germany; 13German Breast Group, Neu-Isenburg, Germany; 14HELIOS Klinikum, Berlin-Buch, Germany and 15Institut für Pathologie, Charité-Universitätsmedizin, Berlin, Germany.

Background: The GeparNuevo trial is a randomized, double-blind, multi-center phase II trial of neoadjuvant therapy in patients with early-stage triple negative breast cancer (TNBC) investigating the role of durvalumab, an anti-PD-L1 antibody, which blocks PD-L1 binding to PD1 and CD80, in addition to standard anthracycline/taxane based chemotherapy (Loibl S et al. ASCO 2018).

Methods: In order to determine possible predictive or prognostic biomarkers, blood samples were taken before and during the different treatment phases (3 or 4 time points) and evaluated by multicolor flow cytometry by monitoring the absolute cell counts of T cells, B cells and NK cells as well as the frequency, composition and functionality of different immune cell populations using a panel of 35 distinct antibodies.

Results: Overall 174 patients were randomized into the GeparNuevo study. 117 patients participated in the window phase of this study and 49 patients provided evaluable material for flow cytometric analyses for material at the above specified time points. Evaluation of the absolute cell count in the whole blood prior and after therapy highlighted a mixed behavior of the total leukocytes. Overall, there was a statistically significant reduction in the lymphocyte count, particularly during the last phase of the treatment (ECdd +/- durvalumab). Further dissection into the different immune populations highlighted an almost complete loss of B cells, which in some patients was also accompanied by a reduction of NK cells, mainly of the CD16+ subset. The loss of CD4+ and CD8+ T cells was less pronounced resulting overall in an enhancement of their percentages within the total lymphocytes. In addition, the different populations have also been evaluated for the expression of PD-L1 activation and exhaustion markers. A pre-specified analysis clearly demonstrated a specific effect of durvalumab during the window phase with mean decreases of 21.7% and 15.0 % in PDL1+ lymphocytes in the CD4+ and CD8+ subgroups, respectively (P<0.001). Currently, all data generated are statistically analyzed focusing on their clinical significance in relation to the treatment received and the pathological complete remission (pCR) of these patients.

Conclusion: Using this approach we hope to identify biomarkers, which will allow a better selection of TNBC patients undergoing specific immunotherapies. Final data will be presented at the meeting.

The trial and this translational research project were funded by AstraZeneca and Celgene, Germany.
Chemoimmunotherapy with cyclophosphamide plus a toll-like receptor 9 (TLR9) agonist eradicates triple negative breast cancer in a murine model

Michael J Campbell1, Vickram Tandon1, Balim Senman1, Jiali Li1 and Laura Esserman1. 1University of California, San Francisco, CA.

Background. Toll-like receptors (TLR) recognize conserved molecular patterns expressed by microbes and together with other molecular sensors serve as a first line of defense, inducing soluble and cellular mediators of innate immunity and initiating key steps of an adaptive immune response. The use of TLR agonists for therapeutic purposes relies on the ability of these compounds to induce, at least partially, some of the immune events that occur during natural infections. For example, synthetic CpG-containing oligodeoxynucleotides (ODN) act as TLR9 agonists, mimicking stimulation of the immune system by bacterial or viral DNA. CpG ODNs are being developed for cancer immunotherapy based on their capacity to stimulate innate and adaptive anti-tumor responses. In this study, we examined the efficacy of intratumorally administered CpG-ODN 1826 alone or in combination with immunomodulatory antibodies (anti-PD-1, anti-OX40, anti-CTLA4) or chemotherapy (cyclophosphamide, paclitaxel) in the syngeneic mouse 4T1 breast tumor model.

Methods. Tumors were implanted orthotopically in the mammary fat pads on the left and right flanks while only one tumor was injected with CpG-ODN 1826. Therapy began 12-14 days post tumor injection when tumors were 8-10 mm in diameter. CpG-ODN 1826 (100 ug) was administered intratumorally, while immunomodulatory antibodies (anti-PD-1 [200 ug], anti-CTLA4 [100 ug], anti-OX40 [400 ug]) and chemotherapies (cyclophosphamide [150 mg/kg], paclitaxel [10 mg/kg]) were administered intraperitoneally. Tumor volume was monitored on both flanks to assess direct and abscopal/systemic anti-tumor activity. Tumor tissue obtained during the treatment regimen was used to evaluate therapy-induced changes in the immune microenvironment.

Results. CpG-ODN 1826, administered intratumorally over 5 consecutive days induced complete regressions in ~50% of the treated tumors, but only delayed growth in the distant lesions. The immunomodulatory antibodies had little effect on their own and did not add to the therapeutic efficacy of CpG-ODN 1826. The best therapeutic efficacy was obtained with a combination of weekly cyclophosphamide + CpG-ODN 1826 resulting in complete regression of both the CpG injected tumors and the contralateral tumors in 100% of the mice.

Conclusions. These data support the clinical investigation of the combination of a TLR9 agonist (CpG-ODN) with cyclophosphamide in women with breast cancer.
Introduction: Triple negative breast cancer (TNBC) constitute 10-20% of all breast cancers and is associated with a worse prognosis and limited treatment options. Recent trials evaluating immune checkpoint blockade in TNBC demonstrated encouraging results for a subset of patients. TNBC is highly heterogeneous and its tumour microenvironment (TME) has been recognized as a critical determinant of its behavior and clinical outcome. Genome-wide gene expression profiling analyses have already improved our understanding of the complexity of this disease and have defined 6 different molecular subtypes namely Basal-like 1 (BL1), basal-like 2 (BL2), immunomodulatory (IM), mesenchymal (M), mesenchymal stem-like (MSL) and luminal androgen receptor (LAR), exhibiting distinct biological and clinical characteristic.

In this study, we aim to dissect the molecular diversity of the TME and more specifically to assess the immune landscape according to TNBC molecular subtypes.

Methods: A cohort of 485 TNBC patient with publicly available data (RNA-Seq and Illumina HT-12 v3) from the METABRIC and the TCGA consortia were used in the gene expression analysis. Gene signatures reflecting different features or cellular components (immune, stromal, angiogenesis, lymphangiogenesis, hypoxia, metabolism) of the TME were used to evaluate multiple biological processes known to contribute to tumorogenesis. A compendium of 17 immune specific gene signatures and T cell localisation classification were used to evaluate the immune composition and spatial pattern of immune infiltrates. All parameters were compared using a logistic regression model to evaluate their relative contribution according to each molecular subtype.

Results: Our analyses demonstrated that each molecular subtype exhibits different TME profiles, as well as specific immune composition and localisation. IM tumors were associated with the highest expression of immune-related gene signatures, enriched with adaptive immune cells and with a fully inflamed spatial pattern. MSL tumors were mostly associated with the expression of Lymphangiogenesis and Stromal TME signatures. They also exhibited some immune activity through the expression of immune gene signatures capturing innate immune and adaptive immunosuppressive cells. This subtype was mainly associated with margin restricted and to some extent with fully inflamed spatial pattern. BL1 tumors were associated with the expression of Metabolism TME signatures, along with fully inflamed and stroma restricted spatial pattern. To a lesser extent, this subtype was also associated with activated DC and CD4 Tem cells. LAR and M tumors exhibited an immune cold phenotype. They were associated with Stromal and Metabolism TME signatures, enriched in margin restricted spatial pattern and negatively associated with every immune cells.

Conclusions: Our results demonstrate for the first time the huge heterogeneity that characterizes the TME of TNBCs. Identification of specific TME profiles could help to design more rationale and appropriate synergistic therapeutic combinations targeting TME elements in this high-risk disease.
Targeting neo-epitopes from *PIK3CA* and *p53* mutations for immunotherapy of breast cancer

Meixuan Chen¹, Padhmavathy Yuvaraj¹, Amit A Sharma¹, Pooja Narang², Melissa A Wilson Sayres¹² and Karen S Anderson¹²³.¹Center for Personalized Diagnostics, Biodesign Institute, Arizona State University, Tempe, AZ; ²School of Life Sciences, Arizona State University, Tempe, AZ and ³Mayo Clinic, Phoenix, AZ.

Introduction: Preclinical data suggests that priming T cell immunity to mutated or overexpressed proteins can induce tumor rejection, and may potentiate the effects of checkpoint blockade. *PIK3CA* and *p53* are the most commonly mutated genes in breast cancer, and are enriched in high-grade and metastatic tumors. Here, we evaluated the immunogenicity of neo-epitopes derived from common *PIK3CA* and *p53* mutations.

Methods: We applied a custom informatics pipeline, EpitopeHunter, to predict neo-epitopes (8-11mers) from twelve *PIK3CA* and ten *p53* mutations restricted to thirty-nine MHC class I alleles. We selected high affinity neo-epitopes (IEDB score < 500) with predicted poor binding of the matched wild type epitope. We used the predicted peptides to stimulate PBMC from healthy donors in vitro, and measured T cell immunity by interferon-γ ELISPOT. We compared the T cell specificity of mutant vs wild type epitopes. A positive response to an epitope was defined as a response that met both of the following criteria: 1) net number of spots (after subtracting background) was >5 spots/50,000 cells and 2) net number of spots exceeded the background spots plus two SDs.

Results: In total, 1,824 PIK3CA and 1,520 p53 derived peptide sequences were generated. Of these, 42 PIK3CA (2%) and 45 p53 (3%) peptides were predicted to bind to the HLA class I molecules included in our study. Over 90% of the neo-epitopes were 9- and 10-mers, and the predicted neo-epitopes varied across mutations (range 2-10 per mutation). PIK3CA$^{H1047L}$ and p53$^{R248W}$ had the highest number of potential binding neo-epitopes (n=10 each). We successfully generated T cell lines specific for A$^*$0201 PIK3CA$^{H1047L}$, A$^*$1101 PIK3CA$^{H1047L}$, A$^*$1101 PIK3CA$^{E542K}$ and A$^*$0201 p53$^{R248W}$.

Conclusions: Common mutations of *PIK3CA* and *p53* can lead to the generation of potential HLA class I restricted neo-epitopes. We identified four immunogenic neo-epitopes, which may serve as candidates for targeted immunotherapy in breast cancer.
PanCancer profiling reveals population difference in breast cancer immune microenvironment

Ahmed Elkhanany¹, Kazuaki Takabe¹, Thaer Khoury¹, Angela Omilian¹, David Cheng², Eriko Katsuta¹, Warren Davis¹, Li Yan¹, Chi-Chen Hong¹, Elisa Bandera³, Christine Ambrosone¹ and Song Yao¹. ¹Roswell Park Comprehensive Cancer Center, Buffalo, NY; ²University of Florida, Gainesville, FL and ³Rutgers Cancer Institute of New Jersey, New Brunswick, NJ.

BACKGROUND. Breast Cancer (BC) outcome in patients (pts) of African ancestry (AA) is worse than pts of European ancestry (EA) despite accounting for socioeconomic status and access. AA have higher hormone receptor negative (HR-) and Triple Negative (TNBC) tumors, subtypes associated with stronger presence of tumor infiltrating lymphocytes (TILs). We hypothesize that BC Immune Microenvironment (IME) composition differs by ancestry, and describe IME from two independent datasets.

METHODS. Transcriptome data from the Cancer Genome Atlas (TCGA) (Group 1, Gp1) were used to estimate 22 IME cell types in BC samples by CIBERSORT. Clinical and overall survival (OS) data were accessed from XENA. Gp2 tissue samples were obtained from Women's Circle of Health study and Pathology Resource Network at Roswell Park Comprehensive Cancer Center and processed using NanoString™ PanCancer Immune Profiling panel, consisting of 770 immunity-related genes describing 24 IME cell types. Immune Dysfunction and Exclusion (TIDE) scores were derived from an algorithm by Jiang et al.

RESULTS. Gp1 consisted of 183 AA and 752 EA, with median age older in EA (54.5 vs 59). On CIBERSORT IME analysis by race, AA had higher IME infiltrates including macrophages (Mp), dendritic cells (DC) and TILs; notably T regulatory (Treg) and T Follicular Helper (Tfh) cells. The ratios of Tregs and Tfh to total TILs were also elevated. When stratified by subtypes, AAs with TNBC/Basal-like BC had higher Tregs and Tfh cells. CD8+ cells were higher in HR+ and high-grade AA pts only. CD4+/total T-cells was higher in AA across all subtypes, and predicted worse OS (HR 3.15[1.07-9.2]). Gp2 had 190 AA and 177 EA with comparable median age at diagnosis (53 versus 54) and tumor grade. By subtype, TNBC had significantly higher total TILs, CD45+, CD8+, exhausted CD8+, Treg, cytotoxic T cells, B, natural killer (NK), activated NK, DC and Mp; yet significantly lower mast cells and neutrophils (p <0.01). CD8+/Exhausted CD8+ and CD8+/Treg ratios were lower in TNBC and higher-grade tumors, and lowest in HR- grade III. Most of immune pathways were enriched in HR- tumors, with only exception being cell cycle genes being remarkably enriched in HR+ tissues (p <0.01). TIDE demonstrated high immune dysfunction in HR- and high exclusion in HR+ tumors. When compared to EA, AA had more TILs, including B, cytotoxic T-cells, exhausted CD8+, NK, activated NK and Tregs (p <0.01). Neutrophils, Mp and CD8+ were higher in EA. EA also had significantly higher ratio of immune cell types to total TILs across cytotoxic, exhausted CD8+ and Tregs, as well as persistent higher neutrophils, Mp and CD8+ ratios. CD8+/Treg ratio was higher in EA. Consistent with Gp1; CD4+/total T-cell ratio was higher in AA across all subtypes.

CONCLUSION. IME differed significantly by HR, grade and ancestry. Aggressive BC demonstrated stronger overall immune response but dysfunctional IME phenotype (higher Treg, lower granulocytes and mast cells ratios). AA had more TILs across all subtypes, but lower ratios of activator (CD8+, Cytotoxic) to suppressor TILs (Treg, exhausted CD8+), demonstrating immune tolerance and immune-desert model, exception being persistently high fraction of CD4+ ratio predicting worse OS.
Comparison of the immunological and clinical effect of personalized peptide vaccination for patients with breast cancer

Uhi Toh¹, Mina Okabe¹, Yuka Tanaka¹, Takahiro Shigaki¹, Miki Takenaka¹, Nobutaka Iwakuma¹, Tomoya Sudo¹, Akira Yamada², Shgeki Shichijo³, Kyogo Itoh³ and Yoshito Akagi¹. ¹Kurume University School of Medicine, Kurume, Fukuoka, Japan; ²Research Center for Innovative Cancer Therapy, Kurume University, Kurume, Fukuoka, Japan and ³Cancer Vaccine Center, Kurume University, Kurume, Fukuoka, Japan.

Background: Selected therapeutic personalized peptide vaccines (PPV) were effective for boosting anticancer immune response that was associated with the clinical outcome as a prognostic factor for metastatic recurrent breast cancer (mrBC) ¹-². In this study, we investigated the immunological and clinical effect of PPV as the prophylactic cancer vaccine for non-recurrent but high-risk BC (nrhrBC) patients (pts), and we compared it's features to those of the mrBC pts who had active cancers or became resistant to the standard therapies(TR-mrBC). Methods: Material and Patient eligibility criteria: The peptides were selected from the 31 PPVs according to the results of HLA typing and peptide-specific IgG titers. Pts with a histological diagnosis of BC and their HLA-A molecules should be each of -A2, A3, A11, A24, A26, A31 or A33. The clinical protocols were approved by the institutional review board. (UMIN000003081and 00000184400000). Treatment schedule: A maximum of 4 peptides was administrated as weekly for initial four vaccinations and as biweekly for further inoculations. The concomitant standard endocrine therapy and the chemo-endocrine therapy were available for nrhrBC pts after finishing the standard adjuvant chemotherapy, and for mrBC pts concurrently. Immune and clinical response assessment: Specific T-cell responses, IgG titers and cytokines were evaluated using by interferon (IFN)-γ ELISPOT, Luminecx assay and ELISA system in every 6-8 vaccinations. Toxicity, clinical response and correlation with the immune responses were investigated. Results: 16 pts with nrhrBC, 41 pts with mrBC and 79 pts with TR-mrBC received median 18, 16 and 14 vaccines, respectively. After PPV therapies, peptide-specific IgG and CTLs increased significantly in a total of 47 (77%) and 37(60%) in nrhrBC pts, 102 (63%) and 98 (61%) in mrBC pts, and 150(53%) and 100 (42%) in TR-mrBC pts. Pts experienced Grade 1-3 skin reaction at injection site, no other grade 3 or 4 SAEs were associated with PPV but with the disease progression or combination therapy. The median time to progression (TTP) and overall survival (OS) were not reached in nrhrBC pts, 7.8 and 29 months in mrBC pts, and were 7.5 and 15.9 months in TR-mrBC pts, respectively. The peptide specific CTL response was correlated significantly with OS in nrhrBC pts and the IgG levels were associated with the better OS in either non TR-mrBC pts or TR-mrBC pts. High levels of IL-6, GM-CSF, IFN-g, IL-2 receptor, BAFF were associated with worse prognosis for pts with TR-mrBC. And high levels of GM-CSF and BAFF were associated with worse prognosis for pts with nrhrBC and mrBC, respectively. In contrast, High levels of IL-2 were associated with the better prognosis for pts with mrBC. Conclusion: This study indicated that immunological features of these three groups were different from each other with most potent PPV-induced immune boosting for nrhrBC pts. Pts with mrBC who had lower immune-suppressive cytokine levels had the better prognosis. These results suggested the PPV therapy could be effective for postoperative prophylactic vaccination in patients with nrhrBC. References: 1. Takahashi R, Toh U, et al. Breast Cancer Res. 2014; 2. Toh U, Okabe M, et al. THE BREAST 2015.
Activity of nivolumab alone or in combination with targeted therapies in a humanized BLT-mouse model of human breast cancer

Neil A O'Brien¹, Tong Luo¹, Raul Ayala¹, Suruchi Salgar¹, Dylan Conklin¹, Martina McDermott¹, Scott Kitchen², Valerie Rezek², Christine Horak³, Ute Dugan³ and Dennis J Slamon¹. ¹UCLA-Translational Oncology Research Laboratories, Los Angeles, CA; ²UCLA AIDS Institute, Los Angeles, CA and ³Bristol-Myers Squibb, Lawrenceville, NJ.

**Background:** Recent advances in the field of cancer immunotherapy have increased demand for reliable preclinical models to inform patient selection and rational drug combination strategies. The development of the bone marrow-liver-thymus (BLT) mouse may provide the opportunity to study the complex interactions of human tumor and host immune systems in vivo. Other models are limited by the rapid onset of graft versus host disease (GVHD) and a lack of orderly maturation and trafficking of human T and B cells. In BLT mice, implantation of human fetal liver and thymus fragments beneath the kidney capsule of NSG (NOD/SCID/IL-2Rαβ-/-) mice followed by engraftment of matched ex vivo expanded CD34+ cells supports the production of an almost complete human immune system. In this study, we used this model to assess the efficacy of the anti-PD-1 therapeutic antibody, nivolumab, in combination with targeted therapeutics in specific breast cancer sub-types.

**Materials and Methods:** For triple negative breast cancer (TNBC), the activity of nivolumab was assessed in combination with the PARP1/2 inhibitor, talazoparib, in humanized BLT mice. Xenografts were established by subcutaneous injection of \(5.0 \times 10^6\) MDA-231 (TNBC) cells. Mice (n=5) were randomized into treatment groups as follows; 1) Vehicle control (PBS), 2) nivolumab (10mg/kg QW), 3) talazoparib (0.33mg/kg Q5/2D) and 4) nivolumab+talazoparib. After 21 days of treatment, tumor tissue, serum and PBMCs were collected for biomarker analysis.

**Results:** Successful reconstitution of mature human T and B cells was confirmed in BLT mice 12-weeks post engraftment of donor tissue and CD34+ hematopoietic stem cells. MDA-231 cells injected subcutaneously into the flank of these mice formed palpable tumors (150-200mm³) within 9 days of injection. For vehicle control treated mice, tumors grew (2.5-fold) throughout the 21-day study. Single agent nivolumab induced significant tumor growth inhibition (TGI) relative to vehicle control treated mice at Day 21. Single agent talazoparib also induced comparable levels of TGI as did the combination of nivolumab plus talazoparib. Nivolumab treated mice continued to gain weight throughout the study without overt signs of toxicity. Reversible weight loss was observed in the talazoparib and combination treated arms. Overt signs of GVHD were not observed in any of these animals. Preliminary tissue analysis identified high levels of cell surface PD-L1 protein in control treated MDA-231 xenografts. Further analysis of the treated tumors will provide valuable insight into the mechanism of action of this class of molecule. We are establishing xenograft models of hormone receptor (ER+) positive breast cancer to measure the activity of nivolumab +/- CDK4/6-inhibition in humanized BLT mice and these data will also be presented.

**Discussion:** The data presented here highlight the potential of the PD-1 antibody nivolumab to have activity in TNBC. Furthermore, these findings illustrate the potential of the humanized BLT-mouse to model responses to immune check-point in the preclinical setting. Expanded use of this model may help to identify response biomarkers and inform design of combination therapies using immune oncology molecules and approved targeted therapies.
The spatial localization of immune cells predicts prognosis and response to therapy in inflammatory breast cancer

Christophe Van Berckelaer1,2, Cecile Colpaert3,4, Charlotte Rypens1, Koen M Marien5, Yannick Waumans6, Mark Kockx5, Peter Vermeulen1,3, Luc Dirix1,3, Steven Van Laere1 and Peter Van Dam2. 1Translational Cancer Research Unit, GZA Hospitals & CORE, MIPRO, University of Antwerp, Antwerp, Belgium; 2MOCA, Antwerp University Hospital, Edegem, Belgium; 3GZA Hospitals Sint-Augustinus, Antwerp, Belgium; 4UZA, Antwerp University Hospital, Edegem, Belgium and 5HistogeneX, Antwerp, Belgium.

Introduction
The mechanisms contributing to the aggressive biology of inflammatory breast cancer (IBC) are still under investigation. Our lab reported a 79-gene signature that is shaped by specific immune response programs and discriminates between IBC and non-IBC (nIBC). Furthermore, the presence of cytotoxic CD8+ immune cells is associated with a better prognosis in proliferative subtypes of breast cancer. However, not only the presence of CD8+ cells, but also the interaction with other immune cells plays a role in the functional immune response. In this study we assessed the spatial associations between immune cells in IBC.

Methodology
Affymetrix gene expression data of 105 IBC patients were analyzed using CIBERSORT and xCell modules to narrow down the number of stainings for the immunophenotyping. To analyze the composition of the immune infiltrate, we used five validated antibodies: CD79α (B-cell lineage), CD8 (cytotoxic T-cells), FOXP3 (Tregs), CD163 (Tumor associated macrophages, TAMs) and the SP142 PDL1 antibody.

A standard H&E stained section was used to mark the tumor area on pretreatment biopsy sections. Subsequently, 5 slides were stained according to a validated protocol, scanned and evaluated using VISIOPHARM® software that makes virtual multiplexing possible after the alignment of the scanned images. Using both point pattern analysis and the Morisita–Horn index (MHI), developed for ecological studies, we assessed the co-localization of the different types of immune cells. Currently, we report the result of our validation cohort (30 patient samples).

Results
Most of our IBC patients presented with a hormone receptor positive carcinoma (64.7%). Almost a quarter of the patients (23.3%) with initially localized disease achieved complete pathological response (pCR) after neo-adjuvant chemotherapy (NACT). For every staining we report the median relative marker area (RMA), MHI for colocalization with CD8 applying a square tessellation of 100 µm and the number of cells in a radius of 30 µm around CD8+ cells (direct cell-cell contact) in table 1.

Table 1: Median spatial properties.

The RMA of CD8 predicted pCR after NACT (RMA= 1.07% pCR vs 0.35% no pCR, P=0.04), but was not prognostic for OS (P= 0.445). PDL1 positivity predicted neither pCR nor OS in this cohort. However, OS of patients with more PDL1+ cells (> 0.703) in close contact with the CD8+ cells was significantly shorter (5y OS: 50% vs 68%, P= 0.03).

Interestingly, the colocalization of CD8+ cells with TAMs (MHI= 0.69 no pCR vs. 0.75 pCR, P= 0.04) and CD79α+ B-cells (MHI= 0.63 no pCR vs. 0.69 pCR, P= 0.04) was also associated with pCR after NACT, while the number of CD163+ or CD79α+ cells was not.

Conclusion
In this study we described the dynamic interplay between cancer and immune cells. In a validation cohort of 30 patient samples...
we showed that the colocalization of TAMs or B-cells with cytotoxic T cells was associated with pCR after NACT. Furthermore, patients with more PDL1+ cells around CD8+ cells (r= 30 µm) had a worse prognosis while solely the number of PDL1+ or CD8+ cells was not prognostic. By December we will present data on 179 IBC patients.
Immune related gene expression to explore immune escape in primary to metastatic breast cancer transition

Carlo Fremd¹, Niels Halama¹, Ralph Wirtz², Inka Zoernig¹, Hans-Peter Sinn³, Zsuzsanna Varga⁴, Manuel Feisst⁵, Thomas Deutsch⁶, Florian Schuetz⁶, Andreas Schneeweiß¹, Dirk Jaeger¹ and Markus Wallwiener⁶. ¹National Center for Tumor Diseases, University of Heidelberg, Heidelberg, Germany; ²Stratifyer Molecular Pathology GmbH, Cologne, Germany; ³Institute of Pathology, University of Heidelberg, Heidelberg, Germany; ⁴Institute of Pathology, University of Zürich, Zürich, Switzerland; ⁵Institute of Medical Biometry and Informatics, University of Heidelberg, Heidelberg, Germany and ⁶University of Heidelberg, Heidelberg, Germany.

Background: Targeting programmed cell death receptor I pathway (anti-PD-1/PD-L1) demonstrated objective clinical response rates in a subgroup of patients with metastatic breast cancer with overall response rates of up to 20%. However, the vast majority of breast cancer patients is not responding to immune checkpoint blockade. With regard to the diverse tumor biology of breast cancer and recent data, immune evasion is likely mediated by various, coincident mechanisms. Consequently, our objective was to identify patterns of immune responses during the transition of primary to metastatic breast cancer.

Methods: We performed comprehensive immunohistochemistry on both tumor and immune cells in two independent, matched cohorts of 67 primary and metastatic breast cancer patients. Further, the analysis was integrated with mRNA expression levels (RT-qPCR) of key regulatory and effector function immune genes and clinical as well as histopathologic parameters.

Results: Both, immunohistochemistry and mRNA gene expression profiling of immune genes revealed immunological ignorance, defined as an immunological "cold" tumor by particularly low infiltration of CD8⁺ T cells and corresponding immune gene and effector function, as a key feature of primary to metastatic breast cancer transition. However, CD8⁺ T cell infiltration and effector function (Granzyme B, Interferon-γ) were found to be an independent prognostic marker for PFS and OS. Unsupervised hierarchical clustering and regression analysis identified distinct immune response types according to T-cell infiltration, interferon-γ signalling (IFNG), immunosuppression (IDO, TGF-β, FOXP3) and humoral immune responses (Immunoglobulin κ constant; IGKC). Expression of programmed death receptor 1 ligand (PD-L1), and T-cell immunoglobulin and mucin-domain containing-3 (TIM-3) were linked to CD8⁺ T cells and associated with a better prognosis only in triple negative breast cancer patients. Importantly, induction of CD4⁺ and CD8⁺ T cell infiltration as well as humoral immune responses (IGKC, CXCL13) in matched pairs during progression from primary to metastatic disease, where strongly associated with improved distant disease free and overall survival.

Conclusion: Our findings demonstrate a switch to a less immunoreactive environment in metastatic compared to matched, primary samples of breast cancer patients. Nevertheless, induction of T-cell mediated immunity during tumor evolution, observed across all biologic subtypes, warrants further research with the overall goal to convert immunologically ignorant breast cancers and to stratify future immunotherapies.
Cryoablation of murine mammary tumors induce robust immune response

Jonah D Klein¹, Zachary Aukers², John Kennedy², Robin M Ciocca¹, Jennifer L Sabol¹, Ned Z Carp¹ and U Margaretha Wallon².  
¹LMC, Wynnewood, PA and ²Lankenau Institute for Medical Research, Wynnewood, PA.

**Background:** Breast cancer is traditionally not considered as a highly immunogenic disease. Triple-negative breast cancer (TNBC) is an aggressive form of breast cancer with reported high genomic instability and high mutation rate, indicating the possible presence of neoantigens. Cryoablation, the destruction of cells by ultra-low temperatures, can release these neoantigens and induce a tumor specific immune response. We hypothesized these neoantigens might be sufficient to trigger a robust immune response to prevent and/or reduce spread and relapse of TNBC.

In this pilot study we cryoablated orthotopical 4T1 tumors in immune competent Balb/c mice and compared the results to surgery to evaluate 1) possible induction of immune responses and 2) effects on metastases formation.

**Methods:** We used 4T1 mammary carcinoma cells to initiate tumor growth in the mammary fatpad. Tumors were treated by cryoablation, cryoablation followed by surgery (cryo-surgery), or surgery alone. Tumor growth was followed and allowed to reach 3-4mm in largest dimension. Animals were euthanized 7 days post-treatment and tissues were collected to assess cytokine levels and presence of dissociated 4T1 cells. Single-cell suspensions of tumor, tumor-draining lymph node [TDLN], and spleen were tested for secretion of mouse Th1/Th2 cytokines using a bead array and measured by flow cytometry. Possible metastatic spread was assessed by a clonogenic assay using cells from venous blood, lung, and brain. Cell suspensions were seeded in growth medium supplemented with the selection agent 6-thioguanine, allowing only resistant 4T1 cells to form colonies.

**Results:** Cryoablation transformed tumors into a gelatinous mass surrounded by a fibrotic capsule, as typically seen in the clinic. Frozen sections of tumors revealed a necrotic core and infiltrating lymphocytes in the microenvironment. These animals displayed robust increases of Th1 and Th2 cytokines in both spleen and TDLN compared to animals with cryo-surgery treatment. TDLN of animals with surgically excised tumors secreted only IL-2. Circulating tumor cells were found in animals prior to treatment, while no 4T1 colonies formed from cell suspensions of lung and brain tissue [N=8]. At end-point, the surgery alone group had more 4T1 foci formed from lung and brain [mean foci /animal = 6.25 and 0.75, respectively; N=6] than the other two groups. Two animals in this group progressed and were euthanized early due to numerous lung metastases. The cryoablated group had the lowest number of foci formed in the lung and brain [2.25 and 0 respectively; N=8], and all animals were healthy at the predetermined end-point. Mean foci formation in the cryo-surgery group [N=7] was in-between the two other groups and one animal was euthanized early due to metastatic burden 5 days after surgery.

**Conclusion:** Cryoablation of TNBC can induce stimulatory immune responses in vivo. These immune responses might explain why animals treated with cryoablation, though having circulating tumor cells at the time of treatment, exhibited fewer micro metastatic growths compared to surgery alone and the cryo-surgery combination. On-going experiments aim to identify long-term effects of cryoablation on the formation of metastatic foci and growth.
Biological characteristics and prognostic value of Tfh-like cells in the tumor tissue of breast cancer

Lin-xiaoxi Ma¹, Liang Guo¹, Shyamal Goswami², Teng Li², Chun-mei Cao¹, Xiao-ming Zhang² and Jiong Wu¹. ¹Key Laboratory of Breast Cancer in Shanghai, Collaborative Innovation Center for Cancer Medicine, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China and ²Institute Pasteur of Shanghai Chinese Academy of Science, Shanghai, China.

Objective T follicular helper (Tfh) cells formed in germinal center are a distinct subpopulation of CD4⁺ T cell, with high levels of CXCR5, ICOS, PD-1, Bcl-6 and CXCL13 as their characteristic markers. Secreting IL-21 and helping humoral response are their key features. They have been identified in different types of tumors. However, it still remains unclear in breast cancer. Researches of them may provide new clues to the diagnosis and treatment of breast cancer, especially for the potential immunotherapies. This study was performed to explore the existence and a possible role of Tfh cells in breast cancer.

Method Freshly resected invasive breast cancer tissue from Fudan University Shanghai Cancer Center (FUSCC) were collected, with 27 samples for identifying the presence, phenotype and cytokine-producing capacity of Tfh-like cells and 386 for exploring the correlation between Tfh-like cells and clinicopathological characteristics in breast cancer during 03/2015 to 05/2017. Of all those 386 samples, patients were divided into Luminal A (N=61), Luminal B (HER2-) (N=138), Luminal B (HER2+) (N=72), HER2+ (non-luminal) (N=57) and triple negative (N=58) based on St Gallen International Expert Consensus. Data was analyzed based on the result from Multiparameter Flow Cytometry. The correlation between Tfh-like cells and clinicopathological characteristics in breast cancer was examined with t test or one way ANOVA with Tukey's multiple comparisons test.

Results A subpopulation of PD1⁺CD4⁺ T cells in tumor tissues of breast cancer was identified as Tfh-like cells, with the specific expression of Bcl-6 and CXCL13. Phenotypes of those cells were checked by flow cytometry. They were of a high level of ICOS but negative for CXCR5, suggesting that they were atypical Tfh cells. They had high levels of activated molecules such as CD38, CD71, CD95 and HLADR, showing that they were highly activated. They had high levels of suppressive markers as Tim3, TIGIT, and LAG3, indicating they could have regulatory functions. In addition, Tfh-like cells specifically secreted cytokine IL-21 with stimulation. Data showed that high grade (N=166; mean±SEM, 17.62±0.87) compared with low grade (N=220; mean±SEM, 12.41±0.46) or high Ki-67 level (N=300; mean±SEM, 15.38±0.58) with low Ki-67 level (N=86; mean±SEM, 12.10±0.67), and negative ER expression (N=115; mean±SEM, 17.47±1.05) compared with positive ER expression (N=271; mean±SEM, 13.46±0.50) or negative PR expression (N=177; mean±SEM, 16.87±0.83) compared with positive PR expression (N=209; mean±SEM, 12.77±0.50) was associated with higher frequency of Tfh-like cells (P<0.01 to all). Patients with triple negative had higher frequency of Tfh-like cells than those with Luminal A (difference, 6.83; P=0.0006) and Luminal B (HER2-) (difference, 4.61; P=0.0124). Patients with HER2+ (non-luminal) had higher frequency of Tfh-like cells than those with Luminal A (difference, 5.34; P=0.0146). These results indicate that higher frequency of Tfh-like cells could have negative prognostic influence.

Conclusion Our study defined a PD1⁺Bcl6⁺CXCL13⁺CD4⁺ T cell subpopulation, which specifically secretes cytokine IL-21 as Tfh-like cells. Higher frequency of Tfh-like cells is more likely to be seen in patients with poor prognosis.
Programmed death-1 and programmed death-ligand 1 expression in sporadic breast cancer compared to BRCA germline mutation related breast cancer and male breast cancer

Quirine F Manson¹, Natalie D ter Hoeve¹, Cathy B Moelans¹ and Paul J van Diest¹. ¹University Medical Center Utrecht, Utrecht, Netherlands.

Introduction Programmed death 1 (PD-1) and its ligand PD-L1 seem to have a prognostic and predictive role in a variety of cancer types, especially the ones with a high mutational load and immunogenic profile. Despite that breast cancer is not considered as immunogenic, recent studies suggested that PD-1 and PD-L1 do have a prognostic and/or predictive value in breast cancer, which varies between molecular subtypes. However, the role of PD-1 and PD-L1 in BRCA germline mutation related breast cancer and male breast cancer has not yet been examined. We therefore evaluated the expression of PD-1 and PD-L1 in sporadic, BRCA related and male breast cancer.

Methods Tissue microarrays were constructed of formalin-fixed paraffin-embedded resection material from 257 sporadic, 132 BRCA related and 175 male breast cancer patients and stained for PD-1 and PD-L1 by immunohistochemistry. Expression in BRCA related and male breast cancer was compared to the sporadic group and correlations with clinicopathological features were tested.

Results PD-1 and/or PD-L1 expression was available for 245 sporadic, 145 male and 103 BRCA related breast cancers. PD-1 expression in the BRCA group was significantly higher than in the sporadic group (79.0% vs 64.1%), this in contradictory to the male group, where PD-1 was significantly less often expressed than in the sporadic group (46.9% vs. 64.1%). For PD-L1 expression no significant differences were seen between the groups. In subgroup analysis PD-1 expression was higher in grade 3 tumors compared to the lower grade tumors, which was significant in sporadic and male breast cancer. For PD-L1 a significantly higher expression was observed in grade 3 tumors in BRCA related breast cancer, while a significantly lower expression in grade 3 tumors was seen in the sporadic subgroup. No differences were observed looking at PD-(L)1 expression and molecular subtype.

Conclusion PD-1 expression is higher in BRCA related breast cancer compared to sporadic breast cancer, but lower in male breast cancer. Additionally, PD-1 expression is more frequent in grade 3 tumors. Patients with BRCA related breast cancer might therefore respond better to PD-1 inhibitors than patients with sporadic breast cancer, this in contrast to men with breast cancer.
Single-cell RNA sequencing to delineate changes in tumor microenvironment induced by immunotherapy

Hanne Vos¹, Junbin Qian², Giuseppe Floris¹4, Ines Nevelsteen¹4, Kathleen Lambein¹, Lieze Berben³, Patrick Neven¹4, Hans Wildiers³4, Diether Lambrechts² and Ann Smeets¹4. ¹KU Leuven, Leuven, Belgium; ²Center for Cancer Biology, VIB; Laboratory for Translational Genetics, KU Leuven, Leuven, Belgium; ³Laboratory of Experimental Oncology, KU Leuven, Leuven, Belgium and ⁴Multidisciplinary Breast Centre, University Hospitals Leuven, Leuven, Belgium.

Introduction: Improved understanding of the interplay between the immune system and cancer would lead to more adequate response prediction to immune-checkpoint blockade (ICB) treatment. Furthermore, insight into immune interactions would allow identifying biomarkers for response to ICB. Single-cell RNA sequencing has emerged as a powerful technology to characterize heterogeneity in a large population of cells and opens up opportunities to predict response to therapy.

Purpose: Tracking the effect of a single dose of Pembrolizumab on the tumor microenvironment through single-cell RNA sequencing.

Methods: Single-cell RNA sequencing was performed on tumor tissue of one patient before and 10 days after a 200 mg dose of Pembrolizumab (Keytruda®). Changes in cell (sub)populations were analyzed. Fresh tumor material was obtained from a core needle biopsy at diagnosis and from the resection specimen. Single cell suspensions were converted to barcoded scRNA-seq libraries with the Chromium Single Cell 3’ kit with 10X Genomics platform, aiming for an estimated 5,000 cells per library. The libraries were sequenced using HiSeq400. Expression matrices were generated using CellRanger and analyzed by Seurat package. Dimensionality reduction using principle component analysis was applied to identify major cell types and their subtypes.

Results: The analyzed tumor was a grade 3 invasive ductal adenocarcinoma, hormone receptor negative and HER2+ positive, pT2N0M0. Tumor infiltrating lymphocyte (TIL) count was 30% on core biopsy and 50% on resection specimen. We sequenced a total of 9867 transcriptomes at single cell resolution before and after Pembrolizumab treatment, consisting of 5808 and 4049 cells, respectively. Major cell types of the tumor microenvironment were identified by leveraging single-cell transcriptomics analysis. We observed a sharp decrease in cancer cells after treatment (74% versus 25%), which was accompanied by an increase of tumor infiltrating T cells (18% versus 50%). The residual cancer cells after immunotherapy showed a higher expression of the major histocompatibility complex (MHC), MHC-II in particular. In addition, we found enrichment of B-cells and endothelial cells and a downregulation of fibroblasts and myeloid cells. Furthermore, we analyzed subtypes of each cell type. We found a marked increase in cytotoxic CD4 (6% versus 18%) and cytotoxic CD8 cells (4% versus 12%) in the T cell population. These cytotoxic CD8 cells clearly expressed higher PD-1 after immunotherapy. A decrease in CD4 Tregs, naïve CD4 and intermediate CD8 cells was observed and the B cell enrichment after treatment was mainly driven by the increase of follicular B-cells. The increase of endothelial cells was driven by capillary tumor endothelial but not tip cell population, suggesting vessel normalization rather than neo-vascularization.

Conclusion: Single-cell RNA sequencing provides a powerful tool in detecting changes in the tumor microenvironment induced by immunotherapy, and thus offers new opportunities to predict response to immunotherapy. Thirty-three additional patient samples will be analyzed in the near future, with a special focus on T- and B- cell receptor repertoire.
Role of B lymphocytes and B cell-produced IL-27 in breast cancer progression and drug resistance

Hui Yan¹, Suryavathi Viswanadhapalli², Maria Fernandez¹, Carlos Rivera¹, Gangadhara Sareddy², Paolo Casali¹, Ratna Vadlamudi² and Zhenming Xu¹. ¹UT Health San Antonio, San Antonio, TX and ²The Long School of Medicine, UT Health San Antonio, San Antonio, TX.

How host immune elements, particularly B cells, are hijacked to promote breast cancer (BCa) tumor progression and acquisition of resistance to current endocrine therapies remain largely unclear. Prompted by our recent findings that B cells are a major source of cytokine IL-27 (the heterodimer of IL-27p28 and EBI3), which regulates many immune functions as both a pro-inflammatory and anti-inflammatory cytokine, as well as the high expression of IL-27 receptor genes in the breast, elevated circulating IL-27 in BCa patients and the association of increased IL-27p28 expression with reduced survival in BCa patients overall and ER⁺ BCa patients after endocrine therapies, here we hypothesize that B cells promote BCa tumor progression and drug resistance and do so by producing IL-27. In C57 mice transplanted with ER⁺ E0771 syngeneic medullary breast adenocarcinoma cells, deficiency in B cells in mMT mice resulted in virtually abolished tumor growth, resulting from significantly high tumor cell death. Remarkably, in residual tumors developed in mMT mice after transplantation with a higher load of E0771 cells, B cells, which were absent in the blood and lymph nodes, were accumulated within tumors – at an even higher frequency than that in wildtype C57 mice – and expressed IL-27. Further, like class-switching B cells that respond to IL-27 produced by neighboring B cells to express an IFNγ-induced gene signature in the secondary lymphoid organ during the antibody response, a distinct population of tumor-infiltrating B cells expressed high levels of PD-L1, which could be induced by IL-27 in many immune cell types, including B cells, and several cancer cell types. Finally, IL-27 promoted the growth MCF-7 human BCa cells in the presence of tamoxifen in vitro, consistent with a role of B cell-produced IL-27 in the acquisition of drug resistance by BCa. These, together with the delayed tumor growth in mixed bone marrow chimeric mice with B cell-specific deficiency in IL-27 production, outline a potential role of B cell-produced IL-27 in BCa progression and drug resistance through both BCa cell-intrinsic mechanisms and induction of PD-L1⁺ B regulatory cells that participate in the immune checkpoint in BCa.
Analysis of tumor infiltrating lymphocytes in three age categories of luminal B-like breast cancer patients and its correlation with lymph node involvement and systemic immunosenescence/frailty markers

Lieze Berben¹, Sigrid Hatse¹, Cindy Kenis², Bruna Dalmasso³, Ann Smeets⁴, Hanne Vos⁴, Patrick Neven¹, Giuseppe Floris⁴ and Hans Wildiers¹, ¹Laboratory of Experimental Oncology, KU Leuven and University Hospitals Leuven, Leuven, Belgium; ²University Hospitals Leuven, Leuven, Belgium; ³University of Genoa and Ospedale Policlinico San Martino, Genoa, Italy and ⁴University Hospitals Leuven, KU Leuven, Leuven, Belgium.

BACKGROUND Immunosenescence, the age-related decrease in immune competence, which is characterized by decreased adaptive immunity and increased low-grade inflammation. It may lead to altered tumor immunity. However, immunosenescence markers have not been correlated yet with tumor infiltrating leukocytes (TILs) nor with clinical frailty.

METHODS This is the first study that investigates how age affects the relation between systemic immunity and tumor microenvironment in early luminal B-like breast cancer (BC) in function of age. Luminal B-like BC was defined as grade II-III, ER+, HER2- on core biopsies at inclusion. Three distinct age categories of BC patients were chosen: 35-45 years (y) (N=15), 55-65y (N=19), ≥70y (N=31). Stromal TILs (sTILs) % were assessed according to published guidelines, on representative tumor sections. Further characterization of the TILs by immunohistochemistry, using the antibodies against CD3, CD4, CD8, CD5, CD20, CD68 and FOXP3, is currently ongoing. Immunosenescence was evaluated by looking at eleven inflammatory plasma cytokines and chemokines, circulating insulin-like growth factor-1 (IGF-1), T-cell p16INK4a expression, PBMC subset profiles and expression levels of twenty immune-related microRNAs. In the old age category, geriatric assessment was performed.

RESULTS With increasing age, sTILs % significantly decreased, concomitant with significantly increased plasma levels of several inflammatory cytokines (IL-1α, IL-6) and chemokines (IP-10, IL-8, MCP-1), intermediate monocytes, as well as T-cell p16INK4a expression. Significant age-related decrease was seen for plasma IGF-1, naïve CD8+ T-cells and CD8+ T-cells expressing CD27 and/or CD28. Four immune-related microRNAs showed significantly different expression levels between the age groups: miR-18a decreased with age, miR-155 increased with age, miR-19b and miR-20a peaked in the middle group. As expected, various correlations exist between the different blood immunosenescence markers. The % of sTILs showed weak negative correlations with IL-6, IL-8, IL-1α, MCP-1 and the % of regulatory T-cells. Additionally the % of sTILs and several makers of immunosenescence (MCP-1, miR-20a, miR-155, intermediate monocytes) correlated with components of the geriatric assessment (activities of daily living (ADL), mini nutritional assessment (MNA), mini–mental state examination (MMSE)) and with the Leuven oncogeriatric frailty score (LOFS) in the oldest group. Conversely, lymph node involvement was not associated with the % of sTILs nor with any blood aging biomarker.

CONCLUSION sTILs % and several blood immunosenescence markers significantly differ between young and older luminal B-like BC patients. Some of these markers correlated with markers of clinical frailty as well. These findings suggest that interactions between tumor cells and immune/inflammatory cells differ with age and therefore applicable immune biomarkers and approaches for immunotherapy may vary depending on patients’ age.
Investigating trastuzumab-induced myeloid cell alterations for improving combination therapy in HER2+ breast cancer

Meghan J Bloom¹, Angela M Jarrett¹, Todd A Triplett¹, Anum K Syed¹, Thomas E Yankeelov¹ and Anna G Sorace¹. ¹University of Texas, Austin, TX.

Introduction: The purpose of this study is to identify temporal changes in the identity and cellularity of myeloid cells infiltrating human epidermal growth factor receptor type 2 positive (HER2+) breast cancer following trastuzumab therapy. Trastuzumab is a targeted therapy used in combination with cytotoxic therapies to treat HER2+ breast cancer. Previous data shows that in HER2+ tumors, trastuzumab increases vascular maturation and decreases hypoxia, both of which can sensitize tumors to cytotoxic therapies. Preliminary immunofluorescent data reveals a significant increase in the amount of myeloid cell infiltrates in trastuzumab treated tumors during the same temporal window as vascular and hypoxia alterations. The balance of myeloid cells in the tumor microenvironment (TME) can impact neovascularization, hypoxia, and tumor progression. Thus, we hypothesize that quantifying immune modulation following trastuzumab treatment will identify mechanistic properties of trastuzumab induced vascular alterations in the TME. We present results identifying an increase in various myeloid infiltrates between control and trastuzumab treated tumors in HER2+ breast cancer.

Experimental Design: BT474 HER2+ breast cancer cells were implanted subcutaneously into athymic nude mice. After reaching 250 mm³, tumors were treated with trastuzumab (10 mg/kg) or saline for one week and were excised for analysis on days 0, 4, and 7. Each tumor was cut at the largest cross-section; half was fixed in 10% neutral buffered formalin for immunohistochemistry staining of TME markers (pimonidazole, CD11c, F4/80, CD31, and alpha-SMA), and half was digested for single cell analysis using flow cytometry. Data was analyzed with FlowJo software. Distinct populations of myeloid cells have been quantified in day 4 control (n = 6) and trastuzumab treated (n = 4) tumors. A non-parametric Wilcoxon rank sum test was used to determine statistical differences.

Results and Discussion: Flow analysis revealed a significant (p < 0.05) increase of macrophages in tumors treated with trastuzumab for 4 days compared to control tumors. Spatial immunofluorescent data confirms these findings showing a significant increase in macrophage populations, indicated with increased CD11c+ and F4/80+ co-staining in day 4 treated tumors compared to control (p < 0.01). Additionally, flow cytometry results show a significant (p < 0.05) increase in neutrophils in day 4 trastuzumab treated tumors compared to control tumors. Ongoing studies are evaluating spatial variations in myeloid infiltration (CD11c, F4/80), hypoxia (pimonidazole), and vascular maturation index (ratio of alpha-smooth muscle actin to total CD31 stained vessel count) through immunohistochemistry as well as comparing myeloid infiltration in trastuzumab-treated and control mice on day 7.

Conclusion: Quantifying trastuzumab induced immune-modulation will provide mechanistic insight into how trastuzumab alters the TME and improves tumor sensitivity to treatment. This information will be of great importance to identifying optimal windows to administer combination therapies as well as in the development of novel immunotherapies in breast cancer.

We acknowledge the support of CPRIT RR160005, NCI R01CA186193, and ACS RSG-18-006-01-CCE.
The effect of relieving adenosine-mediated immunosuppression on trastuzumab-mediated antibody-dependent cell-mediated cytotoxicity (T-ADCC) against HER2+ breast cancer cell lines

Nicola Gaynor1, John Noone1,2, Javier Monedero2, Enda E Murphy2, Donal J O’Gorman1,2, John Crown3 and Denis M Collins1.
1National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland; 2School of Human Health and Performance, Dublin City University, Dublin, Ireland and 3St. Vincent's University Hospital, Dublin, Ireland.

Introduction: Trastuzumab (T) is a monoclonal antibody therapy used in the treatment of HER2+ breast cancer. T inhibits HER2 intracellular signalling and is capable of engaging the immune system through ADCC. Adenosine is an important negative regulator of the immune response through its interaction with the A2A receptor (A2AR, ADORA2A). Relieving adenosine-mediated immunosuppression by inhibiting A2AR may improve NK cell-mediated T-ADCC against HER2+ breast cancer cells. In addition, we have previously shown that SKBR3 cells resistant to the EGFR/HER2 tyrosine kinase inhibitor (TKI) lapatinib are less sensitive to T-ADCC and showed increased A2AR protein levels. This study examines the effects of inhibiting A2AR signalling on NK cell-mediated T-ADCC against treatment naïve HER2+ breast cancer cell lines HCC1954 and SKBR3 and lapatinib and afatinib (irreversible pan-HER-family TKI)-resistant sublines of HCC1954 and SKBR3.

Methods: HER2+ breast cancer cell lines SKBR3 and HCC1954 were exposed to afatinib (150nM) or lapatinib (1µM) for 6 months to generate TKI-resistant SKBR3-A and HCC1954-L cell lines. Acid-phosphatase-based proliferation assays were used to confirm resistance to TKI treatment. Western blotting was used to examine A2AR and HER2 protein levels in cell lines. NK cells were isolated from healthy volunteer whole blood by MACSxpress isolation kits. Immune cell-mediated cytotoxicity was determined at a 1:1 (NK cell: TC) ratio over 12 hours using a flow cytometry-based method. Direct cytotoxicity and T-ADCC were determined +/- A2AR agonist CGS21680 (1 µM) and/or A2AR antagonist preladenant (100 nM) for all cell lines. Experiments were carried out three times with three separate volunteer samples with representative results presented.

Results: HCC1954-L cells were 5.3-fold resistance to lapatinib (IC50 1.65 µM +/- 0.22 µM) vs. HCC1954 (IC50 0.31 µM +/- 0.15 µM). SKBR3-A cells were 33-fold resistant to afatinib (IC50 0.28 µM +/- 0.006 nM) vs. the parental SKBR3 cell line (IC50 0.009 µM +/- 0.006 µM). SKBR3 and HCC1954 expressed detectable protein levels of A2AR. A2AR and HER2 levels were not significantly changed between parental and resistant cell lines. Levels of direct cytotoxicity and T-ADCC elicited by NK cells were higher against SKBR3-A (p=0.002) and HCC1954-L cells (p=0.0004) than parental cell lines. The A2AR agonist CGS21680 alone had inconsistent effects on direct cytotoxicity and T-ADCC in all cell lines tested. The addition of A2AR antagonist preladenant to CGS21680, but not preladenant alone, increased T-ADCC against the parental HCC1954 cells by 12.7 +/- 3.4% and parental SKBR3 cells by 9.5 +/- 3.6%. T-ADCC levels in the targeted therapy-resistant HCC1954-L and SKBR3-A cell lines were not impacted by the CGS21680/ preladenant combination.

Conclusions: A HER2-targeted therapy resistance phenotype is associated with increased T-ADCC in the models tested. Inhibition of activated A2AR can increase T-ADCC elicited by NK cells against treatment naïve HER2+ breast cancer cell lines but not TKI-resistant sublines. Further work is warranted to examine the impact of targeting A2AR in HER2+ breast cancer.
Delivering tumour antigens survivin and mucin-1 on virus-like particles for breast cancer immunotherapy

Katrin Kramer1, Donaldson Braeden1,2, Vivienne L Young2, Greg F Walker3, Vernon K Ward2 and Sarah L Young1. 1Dunedin School of Medicine, University of Otago, Dunedin, New Zealand; 2School of Biomedical Sciences, University of Otago, Dunedin, New Zealand and 3School of Pharmacy, University of Otago, Dunedin, New Zealand.

Breast cancer is the most frequently diagnosed cancer in women worldwide. Although there are a variety of treatment options available, breast cancer is a difficult disease to treat and many patients experience recurrence following treatment. We have previously shown that tumour antigens delivered on virus-like particles (VLP) induce a targeted anti-cancer immune response. In this study we investigated whether combining the two tumour antigens survivin and mucin 1 as vaccine targets can induce a superior anti-cancer immune response for breast cancer immunotherapy. VLP were designed to recombinantly express the murine survivin epitope. Following expression of Survivin-VLP, aberrantly glycosylated mucin 1 (MUC1) peptide was conjugated onto the Survivin-VLP using intracellular cleavable bis-arylhydrazone linking strategy. Western Blot analysis and electron microscopy confirmed Survivin-VLP expression and UV absorption confirmed conjugation of the MUC1 peptide to the Survivin-VLP. C57mg.MUC1 breast cancer cells were injected into the mammary fat pad of C57Bl/6 and MUC1 transgenic mice. Once tumours were palpable, mice were vaccinated with the Survivin-MUC1-VLP and controls of DPBS, VLP without antigen or VLP delivering either survivin or MUC1 antigen. Tumour growth and mouse survival were monitored for 80 days. Mice vaccinated with Survivin-MU1-VLP delivering both antigens showed enhanced survival (D78) compared to mice vaccinated with VLP delivering only one of the antigens (D66) and controls (D53). Delivery of two tumour antigens induced an enhanced anti-tumour immune response compared to delivery of single tumour antigens. The induction of multiple immune responses against different tumour antigens may apply additional evolutionary pressure upon tumours, prolonging the ability for tumours to develop resistance, or escape through the proliferation of a resistant subpopulation. The use of VLP for the delivery of multiple antigens and adjuvants represents a promising approach to improve cancer immunotherapy for breast cancer.
MEK inhibitor cobimetinib induces immunogenic cell death and immune-modulatory effects in triple negative breast cancer

Chun-Yu Liu¹, Ka-Yi Lau¹, Ji-Lin Chen¹, Pei-Yi Chu², Chun-Teng Huang³, Wan-Lun Wang¹, Pei-Ju Lien¹ and Ling-Ming Tseng¹.
¹Taipei Veterans General Hospital, Taipei, Taiwan; ²Show Chwan Memorial Hospital, Changhua, Taiwan and ³Yang-Ming Branch of Taipei City Hospital, Taipei, Taiwan.

Background
Triple-negative breast cancer (TNBC) has been associated with a robust tumor immune infiltrate. Tumor-infiltrating lymphocytes (TILs) in TNBC have been demonstrated a prognostic value. The mitogen-activated protein kinase (MAPK) signaling pathway have been shown to regulate the immune response with the production of immunomodulatory cytokines, such as TNFα, interleukin (IL)-1, IL-10, and IL-12. Clinical studies have shown that the high expression level of Extracellular signal–related kinase (ERK), a member of the MAPK pathway, correlates with shorter survival in TNBC patients. Accordingly, ERK is a potential target for anti-tumor and cancer immunotherapy. In this study, we aimed to investigate a MEK inhibitor cobimetinib and elucidate whether the MEK/ERK pathway is implicated in immunogenic cell death (ICD) and/or other immunomodulatory effects.

Methods
Mouse TNBC cell line 4T1 was treated with cobimetinib. The cell viability and cell apoptosis were determined by MTT assay and flow cytometric analysis. Cobimeinib-induced damage-associated molecular patterns (DAMPs), such as cell-surface translocation of calreticulin (CRT), extracellular release of ATP, and increase in high-mobility group box protein B1 (HMGB1) release from dying tumor cells, were examined by immunoblotting and flow cytometric analysis. Further, the molecular mechanisms involving cobimetinib-induced cell death were examined by Immunoblotting. Last but not least, establishment of 4T1 animal model in immunocompetent and immunodeficient mice was conducted to investigate the efficacy of cobimetinib in restoration of immunosurveillance and cancer metastasis in vivo.

Results
The results showed that cobimetinib impaired cell proliferation and induced cell apoptosis in a dose-dependent manner in 4T1 cells. Importantly, cobimetinib treated 4T1 cells elicited ICD, by increasing HMGB1 and ATP release, and by promoting membrane exposure of CRT. The molecular mechanisms involved in cobimetinib-induced DAMPs were partially through the downregulation of p-ERK expression. Moreover, cobimetinib induced processing of procaspase-3 and -8 in 4T1 cells, thereby resulting in caspase activation. In addition, 4T1 tumor bearing immunocompetent mice treated with cobimetinib showed reduced size of primary tumors, fewer lung metastases and increased survival. In addition, we noticed that the tumor-suppressive effects of cobimetinib were much stronger in immunocompetent mice than in immunodeficient mice, evident by distinct mice survival in drug-treated mice. Flow cytometric analysis of murine splenocytes also revealed that cobimetinib treatment increased total number of CD8+ T cells, dendritic cell maturation, and suppressed the number of Myeloid-derived suppressor cells (MDSCs) in immunocompetent mice.

Conclusions
Our findings suggested that the MEK/ERK inhibitor cobimetinib induces ICD in vitro and exerts additional immune-modulatory effects in immunocompetent TNBC mice model. Our study highlights the possibility for the use of cobimetinib as an ICD inducer and immunomodulator for therapeutic intervention in TNBC.

Transcription factor T-bet and PD-L1 expression in tumor microenvironment of triple-negative breast cancer

Hitomi Mori¹, Makoto Kubo¹, Masaya Kai¹, Kanako Kurata¹, Hitomi Kawaji¹, Kazuhsa Kaneshiro¹, Yurina Motoyama¹, Rumi Kuroki¹, Mai Yamada¹, Reiki Nishimura², Masayuki Okido², Yoshinao Oda¹ and Masafumi Nakamura¹. ¹Kyushu University, Fukuoka, Japan; ²Breast Center, Kumamoto Shinto General Hospital, Kumamoto, Japan and ³Breast Center, Hamanomachi Hospital, Fukuoka, Japan.

Background: Many analyzes regarding immunotherapies using checkpoint blockade has made it clear that tumor infiltrating lymphocytes (TILs) plays an important role in treating cancers with high levels of somatic mutations such as triple-negative breast cancer (TNBC). We reported the relationship between TILs and PD-L1 expression, and revealed that high-TILs/positive-PD-L1 expression population in TNBC was associated with better prognosis (Oncotarget 2017). However, its molecular mechanism is still unclear. Meanwhile, T-box transcription factor 21 (T-bet) which regulates effecter T-cells activation is derived by stimulation of T-cell receptor and IL-12. Activated T-cells work as antitumor lymphocytes by enhancing the production of cytokines such as INFγ. We focused on T-bet and examined the function of activated T-cells.

Patients and Methods: This study included 242 patients with primary TNBC who underwent resection without neoadjuvant chemotherapy at our three hospitals between January 2004 and December 2014. The immunohistochemistry scoring for CD8 and T-bet expression on TILs was defined as ≥30 per 0.00625mm². PD-L1 positivity was defined as ≥1% of tumor cells staining positive for PD-L1.

Results: Of the 242 TNBC, CD8 on TILs was expressed as positive in 127 (52.5%) tumors, T-bet on TILs was expressed as positive in 67 (27.7%) tumors, and PD-L1 expression on tumor cells was expressed as positive in 99 (40.9%) tumors. T-bet expression was significantly correlated with CD8 expression (P<0.0001) and PD-L1 expression (P=0.0004). There was no significant difference in recurrence free survival (RFS) and overall survival (OS) regardless of CD8 or PD-L1expression level. Meanwhile, the patients with T-bet-positive tumors had a longer OS, compared to those with T-bet-negative tumors (P = 0.13 in RFS and P = 0.047 in OS). The multivariate analysis revealed that T-bet expression on TILs was an independent and positive prognostic factor for OS(HR = 0.5, 95%CI 0.1-0.9, P = 0.035).

Conclusion: OS was significantly longer among patients with high T-bet expressing TNBC. These results may validate the significance of T-bet as a biomarker for various immunotherapies in TNBC.
Feasibility of syngeneic mice models of breast cancer for research of immune checkpoint blockades

Yong Wha Moon¹, Nahee Park¹, Jin Hur², Kamal Pandey², Young Bin Cho¹, Seung Ki Kim¹, Seung Ah Lee¹, Gun Woo Son¹, Jong Min Jo¹ and Hee-Jung An¹. ¹CHA Bundang Medical Center, Seongnam, Republic of Korea and ²CHA University, Seongnam, Republic of Korea.

Background: With the increasing success of immune checkpoint blockades for cancer treatment, we increasingly need well-characterized preclinical models. Syngeneic mice models (with a fully competent immune system) have advantages that they are easily established and cost less, though they do not reflect genetic complexity of human tumors. We evaluated feasibility of syngeneic mice models of breast cancer by analyzing efficacy of immune checkpoint blockade and dynamic change of tumor immune microenvironment.

Methods: We used syngeneic mice model of JC, 4T1, and EMT6 cells, which are all murine triple negative breast cancer in BALB/c mice. At the time when subcutaneous tumors reach at 50~100mm³, each mice models were divided into 2 groups for treatment versus no-treatment control. In the treatment group, mice version of anti-PD-1 antibody was intraperitoneally injected (q3 days, x 6). Anti-tumor efficacy was monitored by measuring tumor volume. 'Tumor response' was defined as a case with tumor volume less than that of control group by a standard error at a determined time point. Immune microenvironment was evaluated by measuring serum cytokines (IL-2, IL-6, IL-10, IFNγ, and TNFα) with legendplex and immune cells (CD3, CD4, CD8, CD56, and FOXP3) of peripheral blood with FACS before injection of PD-1 blockade, after 1st injection, and when euthanized. Tumor-infiltrating immune cells were evaluated with FACS, when euthanized.

Results: The tumor response rate to PD-1 blockade was highest in the 4T1 model (54.5%, 6/11) compared to JC model (40%, 4/10) or EMT6 model (36.4%, 4/11). Bleeding 3 times and tumor obtainment when euthanized in each mouse were feasible for profiling of cytokines and immune cells. Although before treatment with PD-1 blockade, CD3+T cells in peripheral blood were slightly lower in 4T1 model (18.3±8.1%) than JC model (24.6±4.7%) or EMT6 model (27.9±6.3%), after injection of one dose of PD-1 blockade, CD3+T cells increased 1.5 times in 4T1 model (18.3% to 27.3%), whereas those CD3+T cells decreased slightly in JC model and EMT6 model. Dynamic changes were not observed in other subsets of peripheral immune cells in all 3 models. Serum TNFα (with statistical significance) and IFNγ (with borderline significance) were higher in responders than in non-responders or no-treatment control.

Conclusions: Syngeneic mice models of breast cancer were feasible to investigate immune checkpoint blockades and monitor dynamic change of immune microenvironment. In this regard, such models may be used to evaluate immune checkpoint blockade-based combination therapy as well.
Microenvironment heterogeneity of triple-negative breast cancer reveals distinct immune escape mechanisms and potential driver events

Yi Xiao1, Ding Ma1, Shen Zhao1, Yi-Zhou Jiang1 and Zhi-Ming Shao1. 1Fudan University Shanghai Cancer Center, Shanghai, China.

Background The microenvironment phenotypes strongly affect the immunotherapeutic strategies for triple-negative breast cancer (TNBC). Although the multi-omics profile of TNBC has been comprehensively characterized, few studies have focused on the microenvironment phenotypes of TNBC.

Methods With multi-omics data for the largest single-center TNBC cohort (n=386), we first established a TNBC-specific microenvironment cell signature. We further used single sample gene set enrichment analysis to calculate the relative number of microenvironment cell subsets in each sample. Then, we performed k-means clustering to classify the TNBC microenvironment phenotypes into heterogeneous clusters. Furthermore, we systematically analyzed the extrinsic and intrinsic immune escape mechanisms of different TNBC microenvironment clusters. In addition, we explored genomic alterations that might decrease immune infiltration in certain TNBC microenvironment clusters.

Results We classified the TNBC microenvironment phenotypes into three heterogeneous clusters. Cluster 1 (type 1 “cold tumor”) had low microenvironment cells infiltration. Cluster 2 (type 2 “cold tumor”) was characterized by resting innate immune cells, fibroblasts and endothelial cells infiltration. Cluster 3 (“hot tumor”) was featured by adaptive immune cells infiltration. Analysis of immune escape mechanism revealed that an incapability to attract innate immune cells (resulting in failure of adaptive immunity) led to immune escape of cluster 1. The chemotaxis but inactivation of innate immunity (also leading to failure of adaptive immunity) and low tumor antigen burden resulted in immune escape of cluster 2. High expression of immune checkpoint molecules contributed to immune escape of cluster 3. In addition, we found that tumor infiltrating lymphocytes (TILs) were positively correlated with immune checkpoint molecules expression, while mutation load was negatively correlated with those indicators in triple-negative breast cancer. Analysis of enrichment pathways, mutations and somatic copy number variations between the “cold tumor” and “hot tumor” clusters revealed that amplification of MYC and activation of MYC-related pathways might decrease the immune infiltration of cluster 1. Mutations in PI3K-AKT pathway members and activation of fibroblasts-related pathways might decrease the immune infiltration of cluster 2.

Conclusion Utilizing the largest single-center TNBC cohort with multi-omics data, our study first revealed the heterogeneity of the TNBC microenvironment, with translational significance both clinically and biologically. First, we identified a subtype of “hot tumor” in TNBC (cluster 3), for which immune checkpoint blockers (ICBs) might be effective. TILs and immune checkpoint molecules expression but not mutation load might predict the efficacy of ICBs. Second, we presumed some genomic alterations that might drive “cold tumor” formation in TNBC. Our study represents a step toward personalized immunotherapy for TNBC patients.

B7-H3 and B7-H4 expression in ductal carcinoma in situ of the breast: Associations with clinicopathologic features and T-cell infiltration

Ji Shin Lee¹, Ga-Eon Kim¹, Min Ho Park¹ and Jung Han Yoon¹. ¹Chonnam National University Medical School, Gwangju, Republic of Korea.

Background: With the clinical success of immune check point blockades in treating malignant tumors, there are intense investigations in identifying new pathways to activate immune system by targeting immunoregulatory molecules. B7-H3 and B7-H4 play an inhibitory role in T cell function by limiting proliferation and cytokine production. Although several studies have investigated the expression of B7-H3 and B7-H4 in invasive breast cancers, the information of the B7-H3 and B7-H4 molecules in ductal carcinoma in situ (DCIS) remains uncertain.

The present work was undertaken to evaluate the expression of B7-H3 and B7-H4 in DCIS and its association with clinicopathological features in patients with DCIS. In addition, the association of B7-H3 and B7-H4 expression with the T-cell infiltration was also assessed to investigate its roles in the regulation of tumor immune surveillance.

Materials and methods: B7-H3 and B7-H4 expression was examined in 8 pairs of DCIS tissues and matched normal adjacent tissues at mRNA and protein levels by RNAscope in situ hybridization (ISH) and immunohistochemistry. Immunohistochemical staining of B7-H3 and B7-H4 was done in 79 DCIS samples with known hormone receptor (HR) and human epidermal growth factor 2 (HER2) expression using tissue microarray. In addition, immunohistochemical staining was also performed for the T cell lineage markers CD3 and CD8 in DCIS.

Results: RNAscope ISH and immunohistochemistry of B7-H3 and B7-H4 confirmed their increases in DCIS tissues compared with their corresponding normal tissues. B7-H3 and B7-H4 mRNA and protein expression appeared to be concentrated mainly in the DCIS carcinoma cells. High B7-H3 and B7-H4 expression was observed in 58 (73.4%) and 62 (78.5%) cases with DCIS, respectively. High B7-H3 expression was significantly associated with high nuclear grade and presence of comedo-type necrosis (P < 0.05 and P < 0.05, respectively). B7-H3 expression was higher in the HR--/HER2+ subtypes than in the HR+/HER2− subtype (P < 0.05). B7-H3 and B7-H4 expression tended to be associated with low stromal tumor infiltrating lymphocytes density and was negatively related to the CD3+ and CD8+ T cell infiltrates density.

Conclusions: These results suggest that B7-H3 and B7-H4 may play an important role in immune surveillance mechanisms of DCIS and may be useful targets for immune-based therapy to alter or prevent DCIS progression.
High expressions of CXCR4 and CCR5 are associated with poor prognosis in triple negative breast cancer resistant to neoadjuvant chemotherapy

Neslihan Cabioglu¹, Semen Onder¹, Gizem Oner¹, Hüseyin Karatay¹, Mustafa Tukenmez¹, Mahmut Muslimanoglu¹, Abdullah Igci¹, Ahmet Dinççag¹, Adnan Aydiner², Pinar Saip², Vahit Ozmen¹ and Ekrem Yavuz¹. ¹University of Istanbul, Istanbul Faculty of Medicine, Istanbul, Turkey and ²University of Istanbul, Institute of Oncology, Istanbul, Turkey.

Background: Novel systemic therapies are under investigation for patients with triple negative breast cancer who are resistant to neoadjuvant chemotherapy or having a partial response to neoadjuvant chemotherapy. Immune check point inhibition or blocking other immunologic markers such as chemokine receptors might be alternative pathways for these chemotherapy-resistant patients. Therefore, we investigated various immune check point receptor expressions along with different chemokine receptors.

Method:
Expressions of immunological markers were examined immunohistochemically by staining archival tissue of mastectomy specimen (n=56) using specific monoclonal antibodies for PDL-1 (Ventana SP263 clone kit), CXCR4, CXCR5, CCR5, CCR7, CD73, and CD155. PDL-1 positivity was defined as membranous staining ≥1% in either tumor and/or stromal lymphocytes, whereas positivity of chemokine receptors and CD155 and CD73 were considered as cytoplasmic staining ≥50% and ≥5%, and ≥1%, respectively.

Results: Median age was 47 (24-76) years. Of those, 31 were clinically T3-4 (55%), whereas almost all of them were N1-3 (96.4%) before neoadjuvant chemotherapy. All patients received anthracyclines&paclitaxel containing regimens, whereas 3 patients received additional carboplatin before definitive surgery.
Of those, 30 patients (58%) were detected to be positive for PDL1 in tumor site and intratumoral lymphocytes, whereas CXCR5 (41.1%, 23/56), CCR5 (48.2%, 27/56), CCR7 (41.1%, 23/56), CD155 (30/56, 58%) and CD73 (44.6%, 25/56) were found to be highly expressed in tumors. However, 12.5% of patients have shown high expression of CXCR4. Patients with CXCR5, CCR5, CCR7, CD73, CD155 positivity were more likely found to give a worse chemotherapy response as measured by “Residual Cancer Burden Index”.

Median follow-up time was 36 months (7-177). Five-year disease-free survival (DFS) and disease specific survival (DSS) rates were found to be decreased in patients with CXCR4 (DFS: negative, 55% vs positive, 23%; \( p = 0.079 \) and DSS: negative, 52% vs positive, 23%; \( p = 0.034 \)) and CCR5 positivity (DFS: negative, 63.5% vs positive, 26%; \( p = 0.037 \) and DSS: negative, 61% vs positive, 25%; \( p = 0.047 \)), while no significant difference could be found in DFS and DSS rates in regards to PDL1, CXCR5, CCR7, CD73 and CD155 positivity.

**Conclusion:** These results demonstrate that PDL-1, CD73, CD155 and chemokine receptors are highly expressed in patients with partial response to neoadjuvant chemotherapy. Furthermore, expressions of CXCR4 and CCR5 were found to be associated with poor prognosis in this cohort with triple negative breast cancer resistant to chemotherapy that would justify an additional chemokine receptor inhibitor therapy.
LncRNA NKILA promotes tumour immune evasion by sensitizing tumour-specific t cells to activation-induced cell death

Erwei Song1, Shicheng Su1 and Di Huang1. 1Sun Yat sen Memorial Hospital, Guangzhou, China.

Activation induced cell death (AICD) of T lymphocytes is critical to maintain T-cell homeostasis, which is adopted by malignant tumors to convey immune evasion by eliminating tumor-reactive cytotoxic T cells. In this study, we demonstrated excessive apoptosis of tumor antigen-specific CTLs in breast and lung cancers. However, the mechanism involved in AICD of tumor-specific T cells remains obscure. Here, we demonstrated that NF-kB activity in tumor-specific T cells is high at the early phase of CTL activation induced by breast tumor antigens, but is suppressed at the later phase. This results in massive apoptosis of tumor-specific CTLs challenged by tumor cells. Interestingly, NKILA, an NFκB interacting lncRNA, sensitizes CTLs to AICD by inhibiting NF-κB activities after their activation, leading to tumor immune evasion. In vivo, administering CTLs with NKILA silencing into immunocompromised mice with breast cancer patient derived xenografts (PDXs) effectively inhibits PDX growth by increasing CTL infiltration. Clinically, NKILA was overexpressed in the tumor specific CTLs of breast and lung cancers, which was associated with less CTL infiltration in the tumors and shorter patient survival. Our findings present the first evidence that AICD in tumor-specific CTLs is crucial to cancer immune evasion, and targeting NKILA in CTLs emerges as a novel anti-tumor immunotherapy.
Doxorubicin induces cellular senescence in human breast cancer cells and sensitizes them to cytotoxic T-lymphocytes

Touko Inao¹,², Yuichi Iida², Hitoshi Kotani² and Mamoru Harada². ¹Kakogawa Central City Hospital, Kakogawa, Hyogo, Japan and ²Shimane Univ.Facul.Med, Izumo, Shimane, Japan.

Background “Cellular senescence” is a state in which cells undergo irreversible cell cycle arrest in response to various cellular stresses. Senescence is induced in not only normal cells but also cancer cells when anti-cancer agents trigger DNA damage. Recent studies have revealed additional feature of senescent cells: increased secretion of various secretory proteins, such as inflammatory cytokines, chemokines, growth factors, and MMPs. This newly recognized senescent phenotype, termed senescence-associated secretory phenotype (SASP), reportedly contribute to tumor recurrence and promotion. Alternatively, senescent cancer cells could be good targets in anti-cancer immunotherapy because they are cell cycle-arrested.

Objective In this study, we determined whether “cellular senescence” could be induced by a chemotherapeutic drug doxorubicin (DXR) and whether senescent cancer cells might increase their susceptibility to cytotoxic T-lymphocytes using human breast cancer cells.

Methods and Results A triple-negative (negative for ER, PR, and HER2) human breast cancer cell line (MDA-MB-231) was used. This cell line was treated with DXR for 2 days and examined for their appearance microscopically. The DXR treatment (500 nM) decreased their proliferating ability and increased their cell size. Colony formation assay revealed that cancer cells significantly decreased the number of colonies even with lower doses (3 nM) of DXR. In immunoblot assay, the DXR treatment increased the protein expression of p21, which inhibits cell cycle. In a flow cytometric assay after staining with SPIDER-β-gal, the DXR treatment (500 nM) increased the expression of β-gal in MDA-MB-231 cells. The induction of SA-β-gal in DXR-treated cancer cells were also confirmed by confocal imaging. In addition, the DXR treatment (500 nM) for 2 days beforehand increased their subsequent ability to produce IL-6 and IL-8. Although the DXR treatment (500 nM) decreased the expression of epidermal growth factor receptor (EGFR) on cancer cells, this treatment sensitized them to anti-EGFR chimeric antigen receptor (CAR) T-lymphocytes in apoptosis assay.

Conclusion These results suggest that a chemotherapeutic drug DXR can render MDA-MB-231 cells to be senescent and increase their sensitivity to antigen-specific cytotoxic T-lymphocytes. These findings may provide a rationale of combination of chemotherapy and T cell-based anti-cancer immunotherapy.
Prospective immune-profiling of locally advanced and metastatic breast cancer patients

Bilge Aktas Sezen¹, Sinan Koca², Ozkan Alan³, Stephanie Renzullo⁴, Filiz Ture Ozdemir³, Lina Kozhaya*, Tugba Akin Telli², Ece Karhan⁴, Umit Ugurlu³, Bahadir Gulluoglu³, Faysal Dane³, Fulyen Perran Yumuk³ and Derya Unutmaz⁴. ¹Istanbul Medeniyet University Goztepe Research and Training Hospital, Istanbul, Turkey; ²Umraniye Research and Training Hospital, Medical Oncology Clinics, Istanbul, Turkey; ³Marmara University School of Medicine, Istanbul, Turkey and ⁴Jackson Laboratory for Genomic Medicine, Farmington, CT.

Background: Breast cancer is still not curable with a substantial resistance rate in all subgroups. Alterations in immunological mechanisms are assumed to play a role in pathophysiology and potential efficiency of immunotherapy approaches. Understanding the immunological changes in these patients may have major implications as predictive biomarkers for disease progression. The aim of our study was to determine immune subsets and functions in patient blood between treatment naïve locally advanced and metastatic breast cancer at diagnosis and to compare it with multiple time points during and after different treatments.

Subjects and Methods: The immunological profile of 25 stage II-III patients who were candidates for neoadjuvant treatment and 27 stage IV treatment naïve patients in two comprehensive oncology clinics (Marmara University and Medeniyet University, Istanbul, Turkey) were analyzed. Age-sex-matched healthy samples (n=26) were collected from volunteers. Peripheral blood mononuclear cells (PBMC) isolated from blood samples were frozen. PBMC were thawed and stained using multi parameter antibodies for immune profiling using flow cytometry in Jackson Laboratory, Farmington, CT.

Results: Differences between T cell subsets among patients (metastatic and locally advanced group separately) and healthy controls were assessed. We found significant differences (all p values <0.01) in inflammatory and regulatory T cell subsets both among the two patient groups (metastatic vs locally advanced untreated) and vs healthy controls, at first time point blood samples: 1) Increase in memory CD4+ T cells (CD45RO+) proportions in both metastatic and locally advanced groups (2) Increase in central and effector CD8+ memory (CD45RO+ or CD45RO-CCR7-) T cells only in metastatic group compared to healthy and locally advanced group, 3) Increase regulatory T cells (Tregs) only in locally advanced group compared to healthy and metastatic patients. 4) Perturbations in proinflammatory Th17 cells in both patient groups compared to healthy controls. More extensive immune profiling of these groups and comparison of different time points during- and post-treatment and correlation with clinical data will be presented.

Conclusions: Our results reveal significant differences in potential T cell activation and regulation in locally advanced and metastatic breast cancer patients, suggesting complex immune response at different disease stages. These findings have implications for as predictive indicators for disease progression for development of future immunotherapy strategies.
Adipose PD-L1 modulates checkpoint blockade immunotherapy efficacy in breast cancer

Bogang Wu¹, Xiujie Sun¹, Harshita B Gupta¹, Bin Yuan¹, Fei Ge¹, Jingwei Li¹, Yanfen Hu¹, Tyler J Curiel¹ and Rong Li¹. ¹University of Texas Health San Antonio, San Antonio, TX.

Programmed death-ligand 1 (PD-L1) and its receptor programmed cell death protein 1 (PD-1) play important roles in modulating antitumor immune response and are targeted by checkpoint blockade immunotherapy. While PD-L1 expression in both tumor and host cells is associated with antitumor therapeutic efficacy, the exact contribution of PD-L1 in various tissue and cell compartments to antitumor immune response remains to be elucidated. Here we show that PD-L1 expression is markedly elevated in human and mouse mature adipocytes compared to their preadipocyte counterparts. When co-cultured with mouse splenocytes *in vitro*, adipocytes prevent anti-PD-L1 antibody from activating CD8⁺T cells. Genetic ablation of adipose PD-L1 obliterates the inhibitory effect of adipocytes on anti-PD-L1 antibody. Conversely, enforced PD-L1 expression in preadipocytes confers the antibody-inhibitory activity. GW9662, a pharmacologic inhibitor of peroxisome proliferator-activated receptor γ (PPARγ) in adipogenesis, selectively reduces PD-L1 expression in mouse adipose tissue. The same PPARγ antagonist also enhances the antitumor efficacy of checkpoint blockade antibodies for treating multiple mammary tumors. Our findings provide a previously unappreciated approach to bolster anticancer immunotherapy efficacy and suggest a mechanism for the role of adipose tissue in breast cancer progression.
Investigating the activity of ESR1 allosteric compounds in ER+ breast cancer

Ange Uwimana, Choi Lai Tiong Yip, Rita Das, Qing Cheng, Erik Meredith and Alex L Gaither. Novartis Institutes for Biomedical Research, Cambridge, MA.

Breast cancer (BCa) is the most frequently diagnosed cancer in women worldwide. Approximately 80% of breast cancer is estrogen receptor positive (ER+) with 74% demonstrating high expression of estrogen receptor alpha (ERα). Thus, current endocrine therapies such as selective estrogen receptor degraders (i.e.- Fulvestrant) or selective estrogen receptor modulators (i.e-Tamoxifen) are involved modulation of ER signaling. However, most patients develop resistance to these drugs, and disease progression is common resulting in metastatic disease. Therefore, targeting alternative sites on the surface of has been proposed as an effective therapy to directly block its activity. In the present study, we investigated putative AF2 compounds that can bind to AF2 allosteric sites and inhibit complex formation and transcription of target genes. In the present study, we characterized a series of allosteric compounds using breast cancer cellular assays. MCF7 parental cells were treated with a series of putative allosteric compounds in a seven day CTG cell proliferation assay, and the compound ERX-11 was found to exhibit anti-proliferative activity. Genomic RNA was isolated after overnight treatment with ERX-11 to investigate compounds treatment on the expression of key ER pathway transcription factors via real time PCR. The degradation effect on nuclear ER and cytoplasmic ER after treatment with ERX-11 were assessed via western blots. We successfully characterized a series of putative allosteric compounds with ERX-11 being the only compound that exhibited anti-proliferative activity in both MCF7 parental and LSZ resistant cells. ERX-11 inhibited the activation of ER transcription gene and degradation of nuclear ER. These findings show promising effects of ERX-11 to block the AF2 sites on the binding domain of ERα with potential therapeutics for ER+ breast cancer.
Background: Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer and represents a disproportional share of the breast cancer mortality, primarily due to a lack of targeted therapies. There is a major unmet need for rationally designed novel therapies that can extend survival of patients with TNBC. TNBCs are characterized by a high basal level of endoplasmic reticulum stress, due to high protein turnover and need for proliferation. Recent studies revealed the role of several members of the Nuclear Receptor (NR) superfamily as molecular drivers in TNBC, including the androgen receptor (AR), glucocorticoid receptor (GR) and the orphan NR tailless (TLX).

Methods: Recently, using peptidomimetics, we have developed small molecules that specifically target and block interactions of multiple coregulators with oncogenic NRs. We performed a screen of our 500+ compound peptidomimetic library derived from our ERX-11 oligobenzamide (that was rationally designed to target ERα) for anti-proliferative activity in TNBC cell lines. Identified leads were then validated in multiple TNBC cell lines. In vitro activity was tested using Cell titer glo, MTT, matrigel invasion, and apoptosis assays. Mechanistic studies were conducted using Western blot, reporter gene assays, CRISPR/Cas9 KO and RNA-seq analysis. Xenograft, patient derived xenograft (PDX), patient derived explant (PDE) and xenograft derived explant (XDE) TNBC models were used for preclinical evaluation and toxicity.

Results: We have identified a first-in-class drug (ERX-41) that has potent activity (IC50 = 50-250nM) against all six molecular subtypes of TNBC. Systematic evaluation using CRISPR/Cas9 KO screen and overexpression screen comprising 48 NRs identified TLX as a preferred target of ERX-41. Analyses of primary breast tumors revealed TLX was highly expressed in TNBC. Further, TLX was amplified in nearly 50% of TNBC xenografts (cbioportal.org). Modelling, mechanistic and biochemical studies showed that ERX-41 interact with TLX and selectively blocks its interactions with coregulators. Gene expression analyses revealed both significant reduction of TLX-activated genes (CCND1, WNT7A) and significant activation of TLX-repressed genes (p21) upon treatment with ERX-41 in TNBC models. Gene ontogeny pathway analyses of RNA-seq data in TNBC cells showed that ERX-41 treatment positively correlated with apoptosis. Our ultrastructural studies indicated that ERX-41 enhances endoplasmic reticulum stress in TNBC inducing autophagic flux and subsequent apoptosis. ERX-41 has significant potency against multiple TNBC xenografts and PDXs in vivo, PDEs and XDEs ex vivo, indicating its potential for clinical translation. Pharmacologically, ERX-41 exhibited high oral bioavailability and associated with minimal toxicity upon oral gavage for up to 120 days in animal studies.

Conclusions: We believe that the ability of ERX-41 to block NR signaling and target a critical molecular vulnerability in TNBC and its ability to enhance endoplasmic reticulum stress in TNBC, will revolutionize the therapeutic landscape of TNBC. ERX-41 is oral bioavailable, potent against multiple TNBC molecular subtypes, and is associated with minimal systemic side effects. (supported by NIH grant RO1 CA223828-01)
Immunomodulation of triple negative breast cancer by caffeic acid phenethyl ester (CAPE)

Coral Omene¹, Manan Patel², Kubra Karagoz¹, Michael L Gatza¹ and Mary Helen Barcellos-Hoff³. ¹Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; ²University of Miami Leonard M. Miller School of Medicine, Miami, FL and ³University of California, San Francisco, San Francisco, CA.

Background: CAPE is the major active component of propolis, a widely available, safe, honeybee natural product with anti-inflammatory, antioxidant, and antitumor properties. We have previously shown diverse effects of CAPE in breast cancer. We postulated that CAPE may be useful in primary or secondary prevention for triple-negative breast cancers (TNBC) and evaluated this in a Trp53 null mammary chimera model in which the tumor spectrum is shifted to TNBC when the host is irradiated (Nguyen, 2011). Bioinformatics species comparisons show that TNBC from this model exhibits a spectrum of tumors that is molecularly similar to that seen in human TNBC (Nguyen, 2013).

Methods: The model consists of Trp53 null mammary epithelium transplanted to cleared mammary glands of wildtype mice. Mice irradiated with 1 Gy received transplants 3 days later and were placed on a CAPE or a control diet at 1 month post transplantation that was maintained throughout the experiment. Tumor development was monitored by palpation for up to 18 months. Tumors were immunostained for estrogen receptor (ER) status and ER negative tumors were selected from all the groups for RNA sequencing. TNBC molecular subtypes were determined for control (n=5) and CAPE treated (n=9) samples using methods described by Lehman, 2011. Gene expression signatures consisting of 270 genes was analyzed for functional enrichment to identify patterns of signaling, as well as additional tumor characteristics, in each cohort of tumors.

Results: Host irradiation significantly accelerated tumor growth rate compared to the control sham irradiated mice. CAPE treatment blocked this effect, but did not affect the control tumor growth rate. Resected tumors in CAPE treated mice recurred at significantly longer intervals (40 days in control group versus 90 days with CAPE) and much less frequently than tumors from mice on a control diet. Mean expression analysis showed that CAPE induces a distinct gene expression pattern in ER negative tumors from irradiated mice. As previously described (Ilia-Bochaca, 2014), ER negative tumors from sham irradiated mice on a control diet were enriched in immune response genes. These genes were suppressed in tumors arising in irradiated host, but this effect of host irradiation was abrogated in mice on the CAPE diet. While untreated tumors were classified into the Basal-like 2 (BL2) or Mesenchymal TNBC molecular subtypes, we observed an increase in subtype diversity after CAPE treatment with tumors being classified as Immunomodulatory and Luminal Androgen Receptor (LAR) in addition to BL2 and Mesenchymal subtypes. Consistent with these data, functional enrichment analyses of RNA sequencing data identified increased immune signaling as well as upregulation of a number of signaling pathways including TGFβ, HGF, and EGFR in treated samples.

Conclusion: These findings support the potential use of CAPE to modify the aggressive behavior of TNBC, which may be due to effects on the immune system in which CAPE acts to re-establish anti-tumor immunity. The finding that CAPE treatment shifts the tumor spectrum to Immunomodulatory subtypes suggests that it may be useful both for women at high risk for TNBC and to prevent or delay TNBC breast cancer recurrence, perhaps in combination with immunotherapy.
A novel, first in class Notch transcriptional inhibitor, CB-103 has activity on luminal breast cancer stem cells in combination with fulvestrant

Samarpan Majumder1, Judy Crabtree1, Fokhrul Hossain1, Maximilian Murone2, Rajwinder Lehal2 and Lucio Miele1. 1LSUHSC, New Orleans and 2Cellestia Biotech, Lausanne, Switzerland.

The Notch signaling pathway plays a central role in cellular differentiation, growth and stem cell maintenance. Expression and activation of Notch pathway receptors and ligands have differential outcomes depending on the tissue, localization and cell type. When Notch pathway is aberrantly activated by genetic lesions, it can be a major driver for Notch-dependent cancers and can cause resistance to standard of care treatment. We and others have shown that in Estrogen Receptor (ER)-positive breast cancers, estrogen deprivation caused by endocrine therapy results in Notch1 and Notch4 activation. In turn, Notch1 stimulated ER-dependent transcription in the absence of estrogen, causing endocrine resistance. Combinations of Notch inhibitors and endocrine therapy are effective in preclinical models of ER-positive breast cancer and have shown promising signals in early clinical trials.

Cellestia’s lead development candidate CB-103 is a small molecule, first-in-class, oral pan-Notch inhibitor. CB-103 selectively blocks Notch pathway activation-related gene transcription through binding to a Notch specific protein in the transcription factor complex. The blockade occurs by protein-protein interaction inhibition with a binding site critical for the assembly of the Notch transcription complex. This is a unique mode of action, which allows blocking Notch signaling regardless of the genetic lesions which have activated the pathway.

We have performed mammosphere assays to test the potency and efficacy of this compound on stem cell ability to form sphere. We used two different doses of CB-103; either alone or in combination with a fixed dose of Fulvestrant (30nM), a SERD, in our mammosphere assays. Two different ER+ luminal, endocrine resistant cell lines were tested and compared with their parental controls. From our data, it’s apparent that there is a synergistic effect when using CB-103 in combination with Fulvestrant. It’s also evident that the efficacy of CB-103 is maximal maximizes at the lowest concentration tested in our assays. The combination was effective in 3 out of 4 models. However, the effect of CB-103 on MCF7-TAMR either as a single agent or in combination was not statistically significant.

Cellestia has received regulatory approval to start clinical development with CB-103 in a first-in-human study Phase I – Ila study investigating safety (Ph I) and preliminary single agent efficacy (Ph Ila) of CB-103 in patients with advanced solid cancers and haematological malignancies. Our data support the notion of testing this agent in ER-positive breast cancer in combination with SERDs.
Cyclin dependent kinase 7 (CDK7) inhibition with THZ1 induces mitotic failure and increases genomic instability in triple negative breast cancer

Bryan M Webb¹, Jennifer M Sahni² and Ruth A Keri¹. ¹Case Western Reserve University School of Medicine, Cleveland, OH and ²New York University School of Medicine, Cleveland, OH.

Triple negative breast cancer (TNBC) is highly proliferative and genomically unstable, making these tumors particularly sensitive to anti-proliferative chemotherapies. While efficacious, these drugs induce dose limiting toxicities. Agents that can selectively target proliferation within cancer cells without inducing systemic toxicity should greatly improve patient outcomes from TNBC. In this regard, we have found that TNBC cells are particularly vulnerable to suppression of the transcriptional regulator, LIN9, that controls cell cycle progression. LIN9 mRNA is overexpressed in 66% of TNBCs and is correlated with worse patient outcomes. Moreover, suppression of LIN9 expression induces multi-nucleation, micronucleation, mitotic catastrophe, and cell death and/or senescence. While transcription factors are generally considered “undruggable, LIN9 expression can be pharmacologically suppressed by blocking the activity of cyclin dependent kinase 7 (CDK7) with the selective, covalent CDK7 inhibitor, THZ1. CDK7 inhibitors inactivate RNA polymerase 2 and destabilize the super-enhancer mediated expression of oncogenes. Treatment of three TNBC cell lines (MDA-MB-231, MDA-MB-468, and HCC38) with THZ1 induces G2/M arrest and phenocopies genetic silencing of LIN9. Use of live cell imaging revealed that THZ1 increases the duration of mitosis and also leads to mitosis-associated cell death. Together, these data reveal that CDK7 inhibitors primarily inhibit TNBC growth by causing mitotic dysfunction and potentiating genomic instability by inducing micro- and multi-nucleation. In addition, they suggest that suppressing LIN9 expression by inhibiting CDK7 may lead to a selective approach for targeting proliferation of TNBC and improving patient outcomes from this disease.
Triple targeted combination therapy with tucatinib, palbociclib and fulvestrant is active in hormone receptor and HER2-positive human breast tumor cell lines

Elena Shagisultanova1, Michelle Borakove1, Peter Kabos1 and Virginia Borges1. 1University of Colorado Denver, Young Women Breast Cancer Translational Program, Aurora, CO.

Hormone receptor and HER2-positive (HR+/HER2+) breast cancer displays increased resistance to anti-hormonal and HER2-targeted agents. HER2 and estrogen receptor signaling converge at cyclin D1 and CDK4/6 complex, resulting in the increased cyclin D1 expression and accelerated progression of the cell cycle. Therefore, triple blockade of the estrogen receptor, HER2 and CDK4/6 is reasonable as a novel approach to treatment of HR+/HER2+ disease. Here for the first time we report high activity of novel combination therapy with HER2-targeted small molecule inhibitor tucatinib, CDK4/6 inhibitor palbociclib, and selective estrogen receptor blocker fulvestrant in human breast tumor cell lines.

Methods: HR+/HER2+ human breast tumor cell lines BT474, MDA-MB-361 and UACC-812 were cultured in standard conditions. The subclones of BT474 and MDA-MB-361 resistant to tucatinib and palbociclib were generated by culturing cells in the increasing concentrations of inhibitors over 6 months. Cell survival assays were performed with Cell Titer Glow (Promega, Madison, WI) after 72 hrs of treatment with vehicle, single agents tucatinib, palbociclib and fulvestrant, and with dual and triple combinations. Tucatinib was provided by Seattle Genetics (Seattle, WA), palbociclib and fulvestrant were purchased from Selleckchem (Houston, TX). Protein lysates for western blot were prepared after 24, 48 or 72 hrs of drug treatment at IC70 using RIPA lysis buffer (Thermo Fisher, Waltham, MA) containing protease/phosphatase inhibitors (Roche Diagnostic, Indianapolis, IN). Signals were quantified with NIH ImageJ Imaging Analysis Software or Odyssey Imager software (Li-Cor Bioscience, Lincoln, NE) and normalized to vinculin or alpha-tubulin.

Results: Dual combinations of tucatinib with fulvestrant and tucatinib with palbociclib were synergistic in all three HR+/HER2+ cell lines. Addition of a constant dose of fulvestrant to a combination of tucatinib and palbociclib further improved tumor cell killing in all three breast tumor cell lines tested. Combination of tucatinib and palbociclib resulted in greater suppression of phospho-AKT and total and phospho-CDK2 comparing to either agent alone. Treatment with single agents tucatinib and palbociclib lead to a significant increase of cyclin E expression at 48 and 72hrs after treatment, however, this compensatory mechanism of cell cycle progression was not observed after treatment with tucatinib and palbociclib combination. Experiments with the resistant BT474 and MDA-MB-361 subclones showed that cross-treatment of cells resistant to palbociclib with tucatinib and vice versa suppressed cell growth and decreased expression of phospho-ERK1/2, phospho-AKT, phospho-CDK2 and cyclin E.

Conclusions: In HR+/HER2+ human breast tumor cell lines combination therapy with tucatinib, palbociclib and fulvestrant demonstrated significant synergy, potentially acting through suppression of phospho-AKT and cyclin E pathways, therefore suggesting a promising novel approach to treatment of HR+/HER2+ breast cancer. Clinical testing of tucatinib, palbociclib and anti-hormonal therapy in patients with HR+/HER2+ metastatic breast cancer is ongoing (phase Ib/II clinical trial NCT03054363).
Budesonide and loperamide do not impact the cytotoxicity of neratinib or HER2-directed monoclonal antibodies in HER2+ breast cancer cell lines

Denis M Collins¹, Nicola Gaynor¹, Neil Conlon¹, Giuseppe Gullo², Alex J Eustace¹ and John Crown¹,². ¹Dublin City University, Dublin, Leinster, Ireland and ²St. Vincent's University Hospital, Dublin, Leinster, Ireland.

Background: Neratinib is an irreversible pan-HER tyrosine kinase inhibitor with demonstrated clinical activity in HER2+ and HER2-mutated breast cancers. The main toxicity of neratinib is diarrhea, which is common in the absence of prophylaxis. Preclinical models suggest that neratinib-associated diarrhea may involve inflammatory, bile acid malabsorption and secretory factors. The phase II CONTROL study is currently investigating the prophylactic efficacy of the opioid receptor antagonist loperamide in combination with budesonide (a corticosteroid used for inflammatory gastrointestinal conditions) or colestipol (bile acid sequestrant) on neratinib-associated diarrhea in early-stage HER2+ breast cancer (NCT02400476). This in vitro study examines the impact of loperamide and budesonide on the anti-proliferative activity of neratinib or trastuzumab and pertuzumab in HER2+ or HER2-low breast cancer cell lines.

Methods: HER2+ breast cancer cell lines SKBR3 (estrogen receptor [ER]–), BT474 (ER+), HCC1569 (ER–) and HER2-low, pertuzumab-sensitive MDA-MB-175-VII (ER+) breast cancer cells were investigated using a 5-day acid phosphatase-based proliferation assay to determine the concentrations required to inhibit growth by 50% (IC₅₀). Fixed ratios of drugs were utilised in combination assays to generate Combination Index (CI) values (Calcusyn®) where available. Clinically relevant levels of neratinib, trastuzumab and pertuzumab were utilised in all experiments. Physiologically relevant levels of budesonide (~4.2 nM) and loperamide (~2.5 nM) were exceeded to provide IC₅₀ values for these compounds.

Results: All cell lines tested had neratinib IC₅₀ values in the nM range (Table). Trastuzumab and the trastuzumab/pertuzumab combination did not exceed 50% inhibition in the HER2+ cell lines. In the HER2+ breast cancer cell lines tested, loperamide had no impact on neratinib activity in BT474, enhanced neratinib activity in SKBR3, and the combination of loperamide and neratinib proved synergistic in HCC1569 (CI = 0.77 +/- 0.2). Budesonide produced strong synergism in combination with neratinib in SKBR3 (CI = 0.27 +/- 0.03), had no impact on neratinib activity in BT474 and improved response to neratinib in HCC1569. Loperamide and budesonide improved the activity of trastuzumab and pertuzumab in all three HER2+ models tested, and had no impact on pertuzumab activity in MDA-MB-175-VII. Interestingly, neratinib proved synergistic in combination with pertuzumab in MDA-MB-175-VII (CI = 0.75 +/- 0.5 nM).

Conclusions: Our preclinical results suggest that budesonide and loperamide do not antagonise the anti-proliferative activity of neratinib or HER2-directed monoclonal antibodies in HER2+ breast cancer cell lines.
Role played by autophagy in breast cancer models exposed to new PI3K/AKT inhibitors, GDC-0068 and GDC-0032

Stefania Cocco, Alessandra Leone, Gaetano Buonfanti, Maria José Sisalli, Alfredo Budillon and Michelino De Laurentiis. 1INT Fondazione G. Pascale, Naples, NA, Napoli, Campania, Italy and 2Università degli studi di Napoli "Federico II, Naples, NA, Napoli, Campania, Italy.

Abundant preclinical evidences indicate that stress-induced autophagy in tumor cells is predominantly cytoprotective and that inhibition of autophagy can enhance tumor cell death by diverse anticancer therapies. A major negative regulator of autophagy is the mammalian target of rapamycin (mTOR), activated downstream of PI3K/AKT pathway. mTOR inhibitors, including rapamycin, have been shown to induce autophagy in tumor cells, while the combination of PI3K-AKT/mTOR and autophagy inhibitors shown synergistic effect on increased apoptosis and reduced autophagy (Takeuchi H. 2005). This project aimed to characterize the role of autophagy in Breast Cancer models exposed to new potent Genentech PI3K/AKT inhibitors GDC0068 (Ipatasertib) and GDC0032 (Taselisib) currently in phase III clinical trials on TNBC and ER+ patients. However, the efficacy of PI3K/AKT inhibitors may be limited by resistance mechanisms that result in minimal cell death in tumor cells. In order to investigate the role of autophagy as possible mechanisms of resistance, Ipatasertib and Taselisib have been evaluated in breast cancer cell lines characterized by different receptors profile: TNBC, HER2/c-erb-2 and luminal A cell lines. Our results showed that both drugs are able to induce G1/S cell cycle block and increase of autophagy signaling measured by p62 level and LC3 II/LC3 I ratio and by the percentage of cells exhibiting LC3 positive puncta. In addition, apoptosis increase was also evaluated by measuring positive annexin V staining, by flow cytometry technique, and apoptosis markers, such as PARP and cleaved caspase 3, by immunoblot assay. Furthermore, the supplement of pharmacologic inhibitors of autophagy, such as hydroxichloroquine, were able to reduce cell viability evaluated by both short- and long-term assays in cell lines exposed to Ipatasertib and Taselisib. 3D breast cancer models are ongoing to confirm the synergic effect of PI3K/AKT inhibitors and hydroxychloroquine, in order to provide a new therapeutic combinatorial approach potentially translatable to patients.
Epithelial-mesenchymal transition sensitizes breast cancer cells to paraptosis-mediated cell death via the fungus-derived sesterpenoid, Ophiobolin A

Keighley Reisenauer¹, Yongfeng Tao², Alec Ingros¹, Tim Philip¹, Antonio Evidente², Alexander Kornienko³, Daniel Romo² and Joseph Taube¹. ¹Baylor University, Waco, TX; ²University of Naples Federico II, Naples, Italy and ³Texas State University, San Marcos, TX.

The epithelial-mesenchymal transition (EMT) enables the dissociation of cancer cells from the primary tumor by facilitating tolerance to lack of cell-adhesion, decreasing cellular division and increasing motility of individual cells, which leads to an invasive phenotype that links EMT to metastasis. Furthermore, EMT results in the acquisition of stem-cell markers and an increased ability to initiate tumor growth, supporting the concept that EMT may contribute to the development of a small, persistent sub-population of the tumor called cancer stem cells (CSCs). Cells that have undergone EMT have characteristically suppressed cell cycles, making them resistant to commonly used chemotherapies that target DNA replication or microtubule dynamics, processes essential to replicating cells. Nonspecific treatments can also rely on inducing apoptotic cell death; however, recent debates challenge the efficacy of apoptosis in solid tumors, citing high rates of acquired resistance. Utilizing a compound that induces alternative cell death, namely paraptosis, becomes attractive when these other treatments fail. Relying on an activated gene expression program, paraptosis results in the swelling of the mitochondria and endoplasmic reticulum and Apaf-1-independent alternative caspase-9 activity. Treating with paraptosis-inducing compounds such as Ophiobolin A (OpA) specifically targets otherwise-insensitive CSC and EMT cells to re-sensitize bulk tumor populations to chemotherapies. We describe EMT as a key driver of enhanced sensitivity to paraptosis-induced cell death following short-term treatment with OpA or other paraptosis-inducing compounds. Further, paraptosis selectively eliminates the CSC sub-population by reducing stem cell activity and highlights the potential of this pathway in breast cancer treatment.
Is the 8th edition of the breast cancer TNM staging system an improvement over the 7th edition?

Alan M Nichol1, Caroline A Lohrisch1, Lovedeep Gondara1, Caroline H Speers1 and Karen A Gelmon1. 1BC Cancer, Vancouver, BC, Canada.

Background: The revised 8th edition of the TNM staging system was published on January 25, 2018 (https://cancerstaging.org/references-tools/deskreferences/Pages/Breast-Cancer-Staging.aspx). The new prognostic staging system (PrSS) was developed using the outcomes of 334,243 patients from the National Cancer Database (NCDB) with a median follow-up of 3.5 years after treatment in 2010-2012. The PrSS was created by clustering patients by outcome into the eight sub-stages of the 7th edition TNM anatomic staging system (AnSS) using more than 169 combinations of stage, ER, PR, H2, grade and molecular test results. This study aimed to assess the prognostic performance of the PrSS in an independent cohort with longer follow-up.

Methods: The Breast Cancer Unit Outcomes database was used to identify patients treated without neoadjuvant systemic therapy in 2005-2014, when use of anti-Her2 therapies was routine. Ten-year breast cancer-specific survival (BCSS) was determined using the Kaplan-Meier method. Using age, ER, PR, H2, grade, chemotherapy, type of surgery and radiotherapy variables for the AnSS and the same variables minus ER, PR, H2, and grade, which are built into the PrSS, Harrell's c-indices were calculated to compare the predictive performance of the AnSS and PrSS models (higher quality models have higher c-indices).

Results: The study cohort had 19,581 patients with a median follow-up of 7.3 years. Relative to the AnSS, 5.2% (1009/19,581) had higher prognostic stages and 36.5% (7,149/19,581) had lower prognostic stages. The c-indices were 0.83 for the AnSS and 0.81 for the PrSS. Overlapping 10-year BCSS confidence intervals (CI) were observed for stages IIIB and IIIC, which contained few patients in both staging systems. There were also overlapping CIs for two other anatomic stages: IA & IB and four other prognostic stages: IB & IIA and IIB & IIIA.

Conclusions: For 10-year BCSS, the c-index was higher for the AnSS than for the PrSS. In addition, more statistically distinct stages were observed for the AnSS than the PrSS. The increased complexity of the PrSS did not appear to provide better prognostication than the AnSS in our large series with longer follow-up than the NCDB.
Importance of adverse events during endocrine treatment for the prediction of late distant recurrences

Ivana Sestak¹, Mitch Dowsett² and Jack Cuzick¹. ¹Centre for Cancer Prevention, Queen Mary University London, London, United Kingdom and ²The Institute of Cancer Institute, Royal Marsden NHS Trust, London, United Kingdom.

Background: During endocrine treatment of breast cancer, the occurrence of symptoms related to oestrogen depletion are an important predictor of treatment efficacy. We have previously shown that appearance of vasomotor and joint related symptoms are a useful biomarker for a greater response to endocrine treatment (Cuzick et al., Lancet, 2008). Furthermore a prediction model including clinicopathological parameters (CTS5) has shown to be a good prognostic tool for the prediction of late distant recurrences (DR) (Dowsett et al., JCO, 2018). Here, we assessed whether the occurrence of endocrine related adverse events were predictive of late DR in the ATAC trial.

Methods: The ATAC trial (N=4735) of postmenopausal women with estrogen receptor positive breast cancer treated with 5 years' tamoxifen or anastrozole was used for this analysis. Women who reported symptoms (hot flashes, joint symptoms, gynaecological symptoms) at any time during the trial were compared to those not reporting these symptoms for late DR. Time to late DR, defined beginning at 5 years after randomization, was the primary endpoint. Hazard ratios (HR) and corresponding 95% CIs were estimated by Cox proportional hazards regression models.

Results: 2937 women (62%) who were recurrence free after 5 years, reported either hot flashes, joint symptoms, or gynaecological symptoms during the active treatment period. Women who reported joint symptoms (adjusted for CTS5: HR=0.74 (0.59-0.94)), or gynaecological symptoms (adjusted for CTS5: HR=0.68 (0.47-0.97)) had significantly fewer late DR compared to those not reporting these events during the active 5 years' treatment period. Those who reported any symptom during the treatment period had an overall 34% lower risk of a late DR (univariate: HR=0.66 (0.53-0.83), P<0.001; adjusted for CTS5: HR=0.75 (0.60-0.93), P=0.009). The 5-10 year DR risk for women who reported any symptoms was 7.4% (6.4-8.5) compared to 11.0% (9.3-12.8) for those without symptoms. Women who reported any symptoms and who were randomized to either anastrozole (HR=0.67 (0.48-0.92)) or tamoxifen (HR=0.65 (0.48-0.88)) had significantly fewer late DR compared to those not reporting these symptoms. Women with symptoms on tamoxifen did have better 10-year DR risk compared to those without symptoms on anastrozole (8.1% (6.7-9.8) vs. 9.8% (7.7-12.4)).

Conclusions: This retrospective analysis of the ATAC trial showed that occurrences of endocrine related symptoms during the treatment period are associated with the risk of developing a late DR, irrespective of treatment allocation. Larger effects were found for joint or gynaecological symptoms and remained significant after adjustment for clinical parameters. These findings might help clinicians and patients in their decision making process about extended endocrine therapy.
Looking forward to the TNM 9th edition: Is it time to stage the different breast cancer subtypes as distinct diseases?

Alan M Nichol¹, Caroline A Lohrisch¹, Lovedee Gondara¹, Caroline Speers¹ and Karen A Gelmon¹. ¹BC Cancer, Vancouver, BC, Canada.

Background: For clinical purposes, four subtypes of breast cancer: Luminal A (LumA), Luminal B (LumB), Her2-positive (H2P) and Triple-Negative (TN) are commonly recognized. This study investigated staging them independently as different diseases. The hypothesis was that the anatomic staging system of the 8th TNM edition would have good prognostic performance within each breast cancer subtype, as defined by estrogen receptor (ER), progesterone receptor (PR), Her2 amplification (H2) and grade.

Methods: Using the Breast Cancer Outcomes Unit database, we identified patients treated without neoadjuvant therapy between 2005 and 2009, when use of anti-Her2 therapy (AH2T) was routine for H2+ disease. We approximated the four subtypes of breast cancer described in Table 48.2 of the revised January 25, 2018 version of the TNM 8th edition (https://cancerstaging.org/references-tools/deskreferences/Pages/Breast-Cancer-Staging.aspx) as follows: LumA ER3+ AND PR3+ AND H2- AND (G1-2); LumB All Non-LumA (ER+ OR PR+) AND H2-; H2P All H2+; and TN ER- AND PR- AND H2-. Breast cancer-specific survival (BCSS) was determined for anatomic stages I-IV within each subtype by the Kaplan-Meier method. The predominant usage of hormone therapy (HT), chemotherapy (ChT) and AH2T was compared by subtype for patients < 70 years, who were generally eligible for ChT.

Results: The median follow-up for the 8,640 patients was 10.0 years. The numbers of patients within each subtype were: LumA = 2,288, LumB = 4,097, H2P = 1,374, and TN = 881. The predominant systemic therapies used by subtype were: LumA: HT = 60.2% and HT+ChT = 29.8%; LumB: HT = 45.9% and HT+ChT = 42.1%; H2P: HT+ChT+AH2 = 40.1% and ChT+AH2 = 35.0%; and TN: ChT = 79.1%. The confidence intervals for BCSS in stages I, II, III, and IV were distinct for the four subtypes, as shown in Table 1.

Conclusions: The anatomic staging system provided reliable BCSS prognostication within breast cancer subtypes. Individualizing treatment using anatomic staging within breast cancer subtypes, would permit decisions about the volume of radiotherapy and the need for intensification of systemic therapy to be made using the familiar and time-tested risk metric of disease extent. In the future, as breast cancer subtyping becomes more sophisticated, prognostication using anatomic staging within these distinct diseases should become increasingly accurate.
PD-L1 expression and prognosis in triple negative breast cancer (TNBC): An analysis of 265 patients (pts) treated with standard therapy for stage I-III disease

Maria Vittoria Dieci\textsuperscript{1,2}, Enrico Orvieto\textsuperscript{3}, Vassilena Tsvetkova\textsuperscript{1}, Gaia Griguolo\textsuperscript{1}, Federica Miglietta\textsuperscript{1}, Serena Bonaguro\textsuperscript{1}, Giulia Tasca\textsuperscript{1,2}, Carlo Alberto Giorgi\textsuperscript{2}, Enrico Cumerlato\textsuperscript{1}, Valentina Guarneri\textsuperscript{1,2} and Pierfranco Conte\textsuperscript{1,2}. \textsuperscript{1}University of Padova, Padova, Italy; \textsuperscript{2}Istituto Oncologico Veneto - IRCCS, Padova, Italy and \textsuperscript{3}aulss 5 Polesana, Rovigo, Italy.

Background: Targeting the PD-L1/PD-1 axis has proved to be effective in various cancers, including promising data for metastatic TNBC pts. The evaluation of PD-L1 expression is limited by the lack of standardized methods. Here we sought to evaluate the prognostic role of PD-L1 expression in a large cohort of patients with non-metastatic TNBC treated with standard therapy.

Methods: Consecutive patients diagnosed with stage I-III TNBC (ER and PgR <10%, HER2 0/1+ or ISH non amplified) between May 2012 and December 2015 and treated at the Istituto Oncologico Veneto of Padova were included. All patients received treatment with surgery, chemotherapy (neoadjuvant or adjuvant) and radiotherapy (when indicated).

For each case, one FFPE tumor slide was stained for PD-L1 with the PD-L1 IHC 73-10 Research Use Only assay developed by Agilent Technologies and one slide was stained for cytokeratins with MNF116 (to distinguish MNF116+ tumor cells from MNF116-stromal cells). Digital slides were evaluated by a specifically-developed Visiopharm\textsuperscript{®} software application. Following alignment of the PD-L1 and MNF116 digital slides, the software analyzed PD-L1 expression on tumor cells (% of positively stained tumor cells/total tumor cells) and stromal cells (% of positively stained stromal cells/total stromal cells). Disease-free survival (DFS) was calculated from diagnosis to relapse or death. In survival analyses, PD-L1 was evaluated as continuous and categorical variable.

Results: 265 TNBC pts were evaluated. Median PD-L1 was 2.6% (Q1-Q3 0%-18.6%) on tumor cells and 5.2% (Q1-Q3 0.2%-25.4%) on stromal cells. PD-L1 levels on tumor and stromal cells were positively correlated (spearman's 0.938, p<0.001). For further analyses, PD-L1 on stromal cells was considered. Higher PD-L1 was associated with age <50 yrs (p=0.011), Grade 3 (p=0.003) and Ki67 >30% (p=0.005). Lower PD-L1 was observed in lobular and apocrine tumors (p=0.001). Cox model for DFS showed HR=0.99 (95%CI 0.97-1.00, p=0.059) for every 1% PD-L1 increment.

3-yrs DFS was 86% for pts with PD-L1>20% (n=88, 29%) vs 75% for pts with PD-L1≤20% (n=177, 71%): HR 0.52, 95%CI 0.28-0.97, p=0.039. PD-L1 at 20% cut-off maintained prognostic value in multivariate model including stage (HR 0.48, 95%CI 0.25-0.89, p=0.021).

Of the 265 pts included, 108 received neoadjuvant chemotherapy (NACT). Of the 78 pts with residual disease after NACT, 61 had pre- and post-NACT samples evaluable for PD-L1. PD-L1 increased from pre- to post-NACT: median 2.7% (Q1-Q3 0%-26.9%) vs 20.1% (Q1-Q3 5.9%-41.4%), p<0.001. Pts with PD-L1>20% post-NACT showed improved DFS: 3-yrs DFS 68% vs 43% (HR 0.44, 95%CI 0.20-0.96, p=0.039), whereas PD-L1 pre-NACT did not show significant association with DFS in this subgroup (HR 0.47, 95%CI 0.23-1.40, p=0.218).

Conclusions: PD-L1 expression evaluated with a software-assisted method was prognostic for stage I-III TNBC pts treated with standard therapy. The significant increase of PD-L1 on residual disease post-NACT supports the rationale to evaluate the efficacy of anti-PD-L1 drugs in this high-risk population.
Prediction of distant recurrence using EndoPredict among women with ER-positive, HER2-negative breast cancer with a maximum follow-up of 16 years

Martin Filipits¹, Peter Dubsky¹², Margaretha Rudas¹, Richard Greil³, Marija Balic⁴, Florian Fitzal¹, Zsuzsanna Bago-Horvath⁵, Christian Singer⁶, Dominik Hlausche ², Ralf Kronenwett⁷, Ryan Bernhisel⁸, Jonathan Lancaster⁸ and Michael Gnant¹.

¹Comprehensive Cancer Center, Institute of Cancer Research, Medical University of Vienna, Vienna, Austria; ²Klinik St. Anna, Breast Center, Luzern, Switzerland; ³Salzburg Cancer Research Institute, Cancer Cluster Salzburg, Paracelsus Medical University Salzburg, Salzburg, Austria; ⁴Medical University Graz, Graz, Austria; ⁵Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria; ⁶Clinical Statistics, Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria; ⁷Myriad International GmbH, Cologne, Germany and ⁸Myriad Genetics, Inc., Salt Lake City.

**Background:** EndoPredict has been previously validated as a prognostic test in women with ER-positive, HER2-negative disease who received endocrine therapy only as part of the ABCSG6 and -8 trials. Here, we further evaluate the prognostic value of EndoPredict in this cohort with longer-term follow-up and compare 10-year distant recurrence (DR) and 5-15 years late recurrence according to nodal status.

**Methods:** This analysis included 1702 patients with ER-positive, HER2-negative disease who received endocrine therapy only. Prognostic value of EPclin score and EPclin risk category (high, low) on the risk of distant recurrence adjusted for patient and disease characteristics was evaluated using multivariable Cox proportional hazard models. Kaplan-Meier estimators were used to estimate DR according EPclin class and were compared using log rank test. Analyses were performed for the overall cohort, by nodal status, and for patients who were distant recurrence free at year 5 (late recurrence).

**Results:** The median follow-up was 9.6 years (range 0-16.6), an increase of 4.2 years over previous reports. Reanalysis with longer follow-up confirms that EPclin is a significant predictor of DR after adjusting for clinical factors, regardless of nodal status (Table 1). Overall, 62.6% of patients had low risk EPclin scores and 10-year DR was significantly improved relative to those with high risk scores (p<0.0001; Table 2). When nodal status was considered, 77.8% of node negative tumors and 34.9% of node positive (1-3 PLN) tumors had low risk EPclin scores. Regardless of nodal status, DR was significantly improved for those with low versus high risk EPclin scores (Table 2). Similar results were observed for the patients who were DR free at year 5 (5-15 year follow-up) (Table 2).

**Conclusion:** This reanalysis of previous EndoPredict data with a longer follow-up confirms that EPclin can identify a large group of patients at low risk of distant recurrence after 10 years who might be sufficiently treated with 5 years adjuvant endocrine therapy only, independent of nodal status. Replication of these results for the late distant recurrence between years 5-15 also shows that EPclin scores may also be informative in selecting patients who may safely forgo extended endocrine therapy.

Impact of molecular subtypes on long-term outcomes in triple-negative breast cancer (TNBC) patients treated with adjuvant AC chemotherapy on SWOG S9313

Priyanka Sharma¹, William B Barlow², David R Hout³, Rob S Seitz³, Daniel B Bailey³, Andrew K Godwin¹, Harsh Pathak¹, Kirsten M Timms⁴, Cara Solimeno⁴, Hannah M Linden¹, Peggy Porter⁵, Debu Tripathy⁶, Gabriel N Hortobagyi⁶, Alastair Thompson⁶, Lajos Pusztai⁷ and Daniel F Hayes⁸. ¹University of Kansas Medical Center, Kansas City, KS; ²SWOG Statistical Center/Cancer Research and Biostatistics (CRAB), Seattle, WA; ³Insight Genetics, Inc., Nashville, TN; ⁴Myriad Genetics, Inc., Salt Lake City, UT; ⁵Fred Hutchinson Cancer Research Center, Seattle, WA; ⁶The University of Texas MD Anderson Cancer Center, Houston, TX; ⁷Yale Cancer Center, New Haven, CT and ⁸University of Michigan, Ann Arbor, MI.

Introduction: TNBC is heterogeneous disease with several molecularly defined subtypes (Lehman et al), each of which may be predictive of response to chemotherapy. TNBC molecular subtypes are associated with varied pathological responses to neoadjuvant chemotherapy. However, subtype specific long-term outcomes for TNBC patients treated with uniform adjuvant chemotherapy are not known.

Aims: To characterize long-term outcomes of TNBC molecular subtypes (TNBCtypes) in patients treated with adjuvant doxorubicin (A) and cyclophosphamide (C) on S9313

Methods: SWOG 9313 accrued 3,125 women with early stage breast cancer to two alternative dose schedules of AC with no difference in outcomes between the two arms (J Clin Oncol 2007). From this trial we identified 425 (14%) patients with centrally determined TNBC for whom tissue was available. Microarray profiling was performed on genomic RNA extracted from pre-treatment FFPE tissue. A 101-gene expression model which has shown to reproduce the classification provided by the original 2188-gene algorithm (Ring et al) was applied to the microarray profiling to generate the following TNBCtypes–Basal-Like 1 (BL1), Basal-Like 2 (BL2), Mesenchymal (M), mesenchymal stem–like (MSL), and luminal androgen receptor (LAR). Immunomodulatory +/- (IM) status was assigned independent of the subtypes. Sequencing of BRCA1/2 from tumor DNA was also performed. The subtypes were tested for prognostic effect on DFS and OS using Cox regression model with adjustment for nodal status.

Results: For 425 TNBC patients, the median age was 45 years, 33% were node-positive and 10-year DFS and OS = 66.3% and 74.1%, respectively. A total of 381/424 (89.7%) cases could be classified into TNBCtypes with distribution as follows: BL1=24%, BL2=8%, M=24%, MSL=11%, LAR=9%, unclassified (UNL) =24%. No association between TNBCtypes and race or nodal status was noted. Compared to other subtypes LAR subtype was associated with older age at diagnosis (median age 53 vs 45, p<0.001). Overall 24% of samples were IM+ and 25% demonstrated deleterious tBRCA1/2 mutation. DFS, tBRCA1/2 mutation and IM+ status distribution across different subtypes are provided in the table. All subtypes except for LAR demonstrated a drop in hazard function for recurrence after 5 years.

</table>

Conclusions: In the presence of adjuvant AC, TNBC molecular subtypes have varied prognosis, with BL1 subtype demonstrating the best prognosis and MSL and LAR subtypes demonstrating the worst prognosis. LAR subtype is associated with older age at
diagnosis and continued elevated hazard function for recurrence after year 5. \(tBRCA1/2\) mutations are distributed across all subtypes with the highest prevalence in BL1 and M subtypes. IM+ status was infrequently noted in non-BL1 subtypes. These findings underscore TNBC heterogeneity and the need to account for this heterogeneity in prospective clinical trials.
Discordance between surrogated intrinsic subtypes defined by immunohistochemistry compared with PAM50 in ER positive / HER2 negative early breast cancer. Analysis of value of the status of the progesterone receptor and Ki67

Cesar A Rodriguez1, Cecilia Guillen1, Maria Garcia1, Magdalena Sancho1, Asuncion Gomez1, Dolores Ludena1 and Juan J Cruz1.
1Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain.

Introduction: Classification by intrinsic subtypes by gene expression profiles of early-stage breast cancer (EBC) provides information of prognostic value and constitutes a tool to help in making therapeutic decisions. Several authors have proposed surrogated classifications based on immunohistochemistry results (IHC) in order to facilitate a classification with identical prognostic and predictive value. However, there is evidence that suggests a lack of correlation between these classifications. The aim of this study was to evaluate the correlation between classification by intrinsic subtypes in patients with EBC ER+/HER2neg, obtained by PAM50 and the surrogated classification proposed by St. Gallen 2013.

Methods: Samples from 12 centers from the spanish region of Castilla y León were analyzed by PAM50 (nCounter™/Nanostring) at the University Hospital of Salamanca. The results obtained were compared with the surrogate classification of St.Gallen’13 from local reports. Tumors of patients pre and post-menopausal tests T1-2, N0-N1mi, grade I-II that met criteria for inclusion of the regional evaluation program through Prosigna™ were included.

Results: Between August’15 and December’17, 264 samples were analyzed. All patients were classified by IHC as lum-A or lum-B. In total 113 cases were reclassified by PAM50 (43%). The change of LumA by IHC to Lum-B by PAM50 was 18%, while Lum-B by IHC to Lum-A by PAM50 was 58% (n = 89). In those cases considered Lum-B by IHC based only in a value of Ki67>14% (n = 93), 54% was reclassified to Lum-A. Conversely, when low expression (negative or <20%) of Progesterone Receptor (PR) was used as the single criterion of Lum-B by IHC (n = 44), PAM50 reclassified 33 cases as Lum-A (75%). Applying the Kappa test to analyze the concordance between the 2 tests, a coefficient of 0.203 (low agreement) was obtained, statistically significant (0.000).

Conclusion: The surrogated classification by IHC of intrinsic subtypes in EBC ER+/HER2neg shows a low concordance with PAM50 analysis, and cannot be considered adequate. In particular, the presence of negative or <20% PR as the only criterion seems the least appropriate and should not be recommended for a surrogated classification of a tumor as Lum-B, overestimating the real risk of numerous patients. PAM50 allowed the reclassification in more than 40% of cases, especially csaes considered Lum-B by IHC.
Genomic progression, detected by circulating tumor DNA (ctDNA) sequencing, as an early predictor of disease progression in metastatic breast cancer (MBC)

Marko Velimirovic¹,², Dejan Juric¹,², Andrzej Niemierko¹,², Laura M Spring¹,², Neelima Vidula¹,², Giuliana Malvarosa¹, Megan Yuen¹, Beverly Moy¹,², Steven J Isakoff¹,², Leif W Ellisen¹,² and Aditya Bardia¹,². ¹Massachusetts General Hospital Cancer Center, Boston, MA and ²Harvard Medical School, Boston, MA.

Background: The availability of multiple therapies has transformed the landscape of MBC, but also brought the challenge of selecting the right therapy for an individual patient. Furthermore, in patients with Hormone Receptor positive (HR+) breast cancer who have bone metastases only it may be difficult to assess effectiveness of therapy via imaging. Peripheral ctDNA detection and analysis by next-generation sequencing (NGS) has gained popularity in cancer diagnosis and therapeutics due to its relative noninvasiveness, ease of use, and high sensitivity. Here, we explore the utility of ctDNA change as a predictor for disease progression in MBC. We hypothesized that genomic progression is a harbinger of subsequent radiologic progression in patients with MBC.

Methods: We analyzed change from pre-treatment (baseline) to on-treatment ctDNA mutant allele fraction (MAF) among patients with MBC. Patients receiving standard-of-care therapies or investigational agents on clinical trials at our institution were included. All patients were followed from the date of baseline test until death or data cutoff (6/20/2018). All peripheral blood specimens were collected and analyzed between 1/7/2016 and 3/1/2018 via NGS (Guardant360®). Peripheral blood specimens were sequenced prior to initiation of a new therapeutic regimen (baseline) and subsequently at least once while on-treatment, on average 4-12 weeks later. All patients had a follow-up CT scan of chest, abdomen and pelvis 2-4 weeks after the on-treatment NGS. A priori, we defined genomic progression as increase in ctDNA total MAF of at least 20% from baseline. We utilized Cox regression analysis to identify whether genomic progression was a predictor of radiologic progression, adjusting for common prognostic variables.

Results: All patients (N= 77) were female, predominantly White (83.1%), and median age was 57 (range 32 to 77). Fifty one out of 77 patients (66.2%) were ER+, 5 HER2+, and 9 had triple negative breast cancer. The median MAF at baseline was 2.2% (range 0% - 61.7%). Common genomic alterations in ctDNA included PIK3CA, TP53, ESR1, AKT1, NF1. 27 out of 77 (35%) patients showed disease progression on the first subsequent CT scan, while 59 out of 77 (76.6%) progressed during the follow up time. We found that an increase in ctDNA MAF of at least 20% was a strong predictor of disease progression (HR =2.46, CI [1.14-5.32], p=0.02), compared to those who had a MAF increase of less than 20% or a decrease in total MAF. In multi-variable analysis, adjusting for age, number of prior therapies, type of therapy, and visceral metastases, increase in ctDNA remained a significant predictor for subsequent disease progression (HR =3.84, CI [1.63-9.07], p=0.002). Subset results in patients with bone metastases only, and relative comparison of ctDNA with standard tumor markers will be presented at the meeting.

Conclusions: Genomic progression, identified by an increase in ctDNA MAF, is potentially an early predictor of subsequent disease progression in patients with MBC. Further research is needed to prospectively evaluate the clinical utility of ctDNA change as a surrogate marker in guiding treatment decision-making for patients with MBC.
DNA methylation markers predict recurrence-free interval in triple-negative breast cancer

Mary Jo Fackler¹, Sean Soonweng Cho¹, Leslie M Cope¹, Edward Gabrielson¹, Kathleen Wilsbach¹, Charles Lynch², Jeffrey R Marks³, Joseph Geradts³, Meredith M Regan¹, Giuseppe Viale⁵, Antonio C Wolff¹, Christopher B Umbricht¹ and Saraswati Sukumar¹. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²State Health Registry of Iowa, Iowa City, IA; ³Duke University Medical Center, Durham, NC; ⁴Dana-Farber Cancer Institute, Boston, MA and ⁵Istituto Europeo di Oncologia, Milan, Italy.

BACKGROUND. Chemotherapy remains the treatment mainstay for triple-negative breast cancer (TNBC). Nevertheless, randomized trials have shown that not all TNBC require it, nor does it benefit all patients that receive it. Molecular tools to risk-stratify TNBC are currently lacking. In light of the importance of epigenetic processes modulating gene expression, we performed an array-based genome-wide DNA methylation search in well-documented institutional and clinical trial cohorts of TNBC for markers that can distinguish breast cancers with a favorable natural history from those with a high risk of recurrence.

METHODS. We performed an array-based genome-wide DNA methylation survey of well-documented institutional and clinical trial cohorts of TNBC and conducted molecular marker discovery on institutional TNBCs (115 patient samples; 53 recurrences) treated by locoregional therapy (LRT) alone. The identified hypermethylated gene signatures were then tested in a TNBC cohort (50 patient samples; 16 recurrences) from the no chemotherapy arms of IBCSG trials VIII and IX, and in a separate combined cohort of TNBCs (131 patient samples; 33 recurrences) treated with chemotherapy from an institutional repository and from IBCSG trials VIII and IX. Cross platform validation was conducted using quantitative multiplexed methylation specific PCR (QM-MSP) on hypermethylated markers in samples from both the Discovery Set and IBCSG LRT Test Set.

RESULTS. We identified methylation signatures in the discovery cohort consisting of 100 or 30 CpG probes that discriminated patients who remained recurrence-free from those with recurrent disease. These signatures were then tested in the IBCSG no chemotherapy cohort, and we found that hypermethylation was associated with shorter recurrence-free interval (RFI). A significant association of both 100 CpG (P<0.0001) and 30 CpG (P=0.0021) signatures with shorter RFI was found in the combined institutional and IBCSG chemotherapy cohort. We observed an enrichment of methylation probes residing on chromosome 19, particularly within 19q13.41-43, that significantly correlated with RFI following chemotherapy. QM-MSP results reflected that of the methylation array [Spearman correlation coefficient of r = 0.495 (P = 0.0009)] indicating that the relationship between high methylation and short RFI is detectable independent of analytical platform. We also observed enrichment for Chromosome 19-specific probes within the 100 and 30 probe sets. While only 5% of all CpG markers are located within Chr19, 15% of the 100 CpG set, 37% of the 30 CpG set, and 47% of the 17 CpGs that are statistically significantly correlated with RFI in the chemotherapy group reside on the Chr19, mostly within 19q13.41-43.

CONCLUSIONS. Methylation markers may be of prognostic importance in TNBC and our findings should be validated in additional clinical trial cohorts.
MammaPrint identifies 46% of patients, age ≤50 years with oncotype RS 18-30, as low risk and safe to forgo chemotherapy.

Hatem Soliman1, Shelly Lo2, Rubina Qamar3, Raye Budway4, Ellis Levine5, Pat Whitworth6, Blanche Mavromatis7, Robin Zon8, Sarah Untch9, Tina Treecce9, Lisa Blumencranz9, William Audeh9, Michaela Tsai10 and PROMIS Investigators Group9. 1Moffitt Cancer Center, Tampa, FL; 2Loyola University Stritch School of Medicine, Maywood, IL; 3Aurora Health, Milwaukee, WI; 4St Clair Hospital, Bethel Park, PA; 5Roswell Park Comprehensive Cancer Center, Buffalo, NY; 6Nashville Breast Center, Nashville, TN; 7Western Maryland Health, Cumberland, MD; 8Northern Indiana Cancer Research Consortium, South Bend, IN; 9Agendia, Inc, Irvine, CA and 10Virginia Piper Cancer Center, Minneapolis, MN.

**Background:** The PROMIS trial (NCT01617954) previously showed that an OncotypeDx (ODx) Intermediate Recurrence Score (RS 18-30) led to uncertainty in prescribing chemotherapy (CT), especially in the middle of the intermediate range from RS 21-26 where an equal number of patients were recommended to receive and forego CT (Tsai, JAMA Oncology 2018). Forty-seven percent (3183/6711) of randomized TAILORx patients were classified as RS 18-25 and are well represented in PROMIS. These patients with RS 18-25 may still lack definitive CT recommendation following TAILORx, reflexing to age and menopausal status to make a decision. Here, we re-evaluate PROMIS using the subgroup analyses adopted by TAILORx. **Methods:** MammaPrint (MP) risk of recurrence was determined for ODx intermediate patients by standard diagnostic testing (Agendia, Irvine, CA). Clinical risk was assessed using the MINDACT, modified Adjuvant Online! algorithm (Cardoso, NEJM 2016). The MP high and low risk classification, and patient and tumor characteristics were re-evaluated and subdivided by RS 18-25 vs. RS 26-30. **Results:** The 840 eligible patients in PROMIS were classified as 61.3% (515/840) clinically low risk and 37.0% (311/840) clinically high risk (including 84 lymph node positive patients). Half (342/684) of all patients with an RS 18-25 and 20.5% (32/156) patients with RS 26-30 were MP low risk.

</table>

There was no significant difference in the distribution of MP risk in women age ≤50 yrs vs. >50 years (Yates chi-square P=0.62); MP classified 46.4% (84/181) patients age ≤50 yrs and 44.0% (290/659) patients age >50 yrs as low risk. In the clinically-low risk subset of 515 patients, there was also no significant difference in the distribution of MP risk by age (Yates chi-square P=0.89); MP classified 48.3% (56/116) patients age ≤50 yrs and 49.6% (198/399) patients age >50 yrs as low risk. **Conclusions:** In light of TAILORx and uncertain CT benefit in women ≤50 yrs, MammaPrint provides a definitive high or low risk answer and identifies 46% of these women who may safely forego CT based on MINDACT data. An analysis of young patients in the MINDACT trial showed that MP low risk patients age <45 yrs and 45-55 yrs had very good 5-yr DMFS of 95-98%, in both clinically low and high risk groups (Alders, SABCS 2017).

First prospective outcome data for the clinico-molecular test Endopredict® in hormone receptor positive, HER2-negative early breast cancer in clinical routine

Johannes Ettl¹, Sophie Anders¹, Alexander Hapfelmeier², Aurelia Noske³, Stefan Paepke¹, Wilko Weichert³, Evelyn Klein¹ and Marion Kiechle⁴. ¹Klinikum rechts der Isar, Technische Universität München, Munich, Germany; ²Institute of Medical Statistics and Epidemiology, Klinikum rechts der Isar, Technische Universität München, Munich, Germany; ³Institute of Pathology, Klinikum rechts der Isar, Technische Universität München, Munich, Germany and ⁴Currently Off Duty; Klinikum rechts der Isar, Technische Universität München, Munich, Germany.

Background: The EndoPredict test is a clinico-molecular test that has been validated to predict the likelihood of distant metastases and late relapse inpatients (pts) with hormone receptor positive (HR+), HER2-negative (HER2-) early breast cancer and up to three positive lymph nodes. However, so far prospective outcome results of pts in whom decision on use of adjuvant chemotherapy (CTX) was based on Endopredict has not been available. Here we present three year outcome data of pts, whose adjuvant systemic therapy recommendation was based on EndoPredict test result.

Methods: Pts with HR+, HER2- early breast cancer with 0-3 positive lymph nodes were enrolled at a single institution (Interdisciplinary Breast Center of Klinikum rechts der Isar, Munich, Germany). The Endopredict test was carried out on all tumor samples. Demographic, clinical and pathological data as well as EPclin risk class were assessed for each patient at baseline. Therapy recommendations were given during an interdisciplinary tumor board. Pts were evaluated for treatment compliance, local recurrence, distant metastases and survival (cut-off date of last follow up: July 31st 2017). Censored time-to-event outcomes were analysed by cox proportional hazards models. Additional estimates of the event-free-survival were given by the Kaplan-Meier method. Hypothesis testing was conducted on two-sided exploratory 5% significance levels.

Results: A total of 373 consecutive pts were enrolled between March 2012 and March 2015. Median age was 59.9 (range: 29.1-88.9) years. In 39% of pts tumorsize was >2cm, 24% of pts were node positive, 16% had G3 tumors, in 21% of pts ki67 was ≥25% and in 13% progesterone receptor was <10%. The EndoPredict test allocated 238 pts (63.8%) in the low-risk group and 135 pts (36.2%) in the high-risk group. 128 of the 373 pts were recommended to undergo adjuvant CTX in addition to endocrine therapy. 92 (72%) of these pts were compliant having received standard of care chemotherapy. After 41.6 months median follow up, 3-year disease free survival (DFS) and distant metastases free survival (DMFS) in the EPclin low risk group was 96.6% (95%CI 94.2-99.1) and 99.6% (95%CI 98.7-100) versus 94.9% (95%CI 90.9-99.0) and 97.6% (95%CI 95.0-100) in the EPclin high risk group. With a hazard ratio (HR) of 2.05 (95%CI 0.85-4.96; p= 0.110) risk for any disease recurrence or death in EPclin high risk patients was two fold higher in comparison with EPclin low risk patients. Patients with EPclin high risk were at significant higher risk of experiencing distant metastases than patients with EPclin low risk (HR 5.18; 95%CI 1.04-25.74; p=0.0443). EPclin high risk patients who actually underwent recommended adjuvant CTX had a 3-year-DFS of 96.3% (95%CI 92.2-100) and were at lower risk for death or recurrence than those EPclin high risk patients without CTX (3-year-DFS: 91.5% (95%CI 82.7-100); HR 0.32; 95%CI 0.10-1.05; p=0.061).

Conclusion: These first prospective outcome results show, that EPclin in clinical routine is a valid clinico-molecular marker to predict DFS and guide decision of adjuvant CTX use in HR+, HER2- early breast cancer pts with 0-3 positive lymph nodes.
Comparative analyses of the prognostic value of oncotype and mammaprint using the National Cancer Database

Abiola F Ibraheem¹, Olufunmilayo Olopade¹ and Dezheng Huo¹. ¹University of Chicago, Chicago, IL.

INTRODUCTION: Majority of the approximately 40,610 deaths from metastatic breast cancer in the US each year occur in women with hormone receptor positive breast cancer who recur after treatment for early stage disease. Genomic analysis is increasingly used to personalize breast cancer treatment for women with early breast cancer resulting in AJCC 8 modification of TNM staging. The 70-gene Mammaprint was developed using both ER- and ER+ breast tissue samples, while the 21-gene Oncotype DX (ODX) assay was developed using only ER+ breast tissue. Previous studies found that the two genomic assays gave discordant testing results.

OBJECTIVE: To compare the performance of Mammaprint and Oncotype DX in assigning prognosis in early stage hormone receptor positive breast cancer.

METHOD: A retrospective cohort of women diagnosed with early stage, hormone receptor positive breast cancer who received ODX or Mammaprint was established using the National Cancer Data Base (NCDB), 2010-2014. Using the propensity score matching method, we defined two groups of patients with similar clinical and demographic characteristics; one group received ODX and another received Mammaprint. The groups were matched by clinicopathologic and demographic factors. We examined the association between ODX or Mammaprint and overall survival using Log-rank test and Cox models in the two groups separately. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated as strength of association. The prognostic values were evaluated using c-index (i.e. area under ROC curve).

RESULTS: Of 320,276 eligible patients with breast cancer, 41.5% received ODX and 1.3% received Mammaprint testing. The use of ODX increased from 34.3% in 2010 to 45.2% in 2014, while the use of Mammaprint increased from 0.5% in 2010 to 2.0% in 2014. After propensity score matching, we identified 3319 patients who received ODX and matched to 3319 patients who received Mammaprint. Compared to patients with a low risk Mammaprint score (n=1915), patients with a high risk Mammaprint score (n=1404) had 4.53-fold increased risk of dying (95% CI 2.79-7.36). The c-index for Mammaprint was 0.683. Relative to patients with a low ODX recurrence score (n=1927), the HR for intermediate ODX score was 1.23 (95% CI 0.76-1.98) and the HR for high ODX score was 3.62 (95% CI 2.21-5.94). The c-index for ODX was 0.601. In patients with ODX testing, 28.2% received chemotherapy. In patients with Mammaprint testing, 42.4% received chemotherapy. Based on MINDACT's modification of AdjuvantOnline, 49.2% patients were assigned to the clinical high risk group, including 22.3% to the clinical high risk/genomic low risk (C-high/G-low) subgroup and 26.9% to the C-high/G-high subgroup. The percentage of patients receiving chemotherapy with C-low/G-low, C-low/G-high, C-high/G-low, and C-high/G-high were 4.3%, 70.4%, 32.2%, and 84.9%, respectively.

CONCLUSION: The findings from our preliminary study suggest that Mammaprint may achieve better separation of high risk from low risk patients. However, it is possible that having more genes in multigene assays would better capture the heterogeneity of hormone receptor positive breast cancer and guide choice of optimal systemic therapy to reduce risk of metastases.
Prognostic significance of CD8+ tumor-infiltrating lymphocytes (TILs) in patients with early breast cancer (EBC) treated with dose-dense sequential adjuvant chemotherapy (dds-CT). An observational study (ACTRN12616001043426)

Helen P Kourea1, Triantafyllia Koletsia1, Vassiliki Kotoula1, Georgia-Angeliki Koliou1, Anna Batistatou1, George Pentheroudakis1, Petroula Arapantoni-Dadioti1, Flora Zagouri1, Matheos Bobos1, Maria Sotiropoulou1, Alexandra Papoudou-Bai1, Sofia Chrisafi1, Ioannis Efstratiou1, Gerasimos Aravantinos1, Irene Nicolaou1, Helen Gogas1, Anastasios Visvikis1, Christos Christodoulou1, Constantina Petraki1, Angelos Koutras1, Amanda Psyrri1, Dimitrios Pectasides1 and George Fountzilas1. 1Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece.

Background - aim: Information on the prognostic role of cytotoxic CD8+ T cells in the era of modern adjuvant CT is limited. The primary objective of the present report is to assess the prognostic impact of CD8+ cells in patients with intermediate or high-risk EBC (T1-3N1-2M0) treated with dds-CT. Secondary endpoints are safety, disease-free survival (DFS) and overall survival (OS).

Patients and Methods: Patients (N=1,000) were treated with 4 cycles of Epirubicin, 75mg/m², and Cyclophophamide, 600mg/m² every 2 weeks followed by 4 cycles of Docetaxel (D), 100mg/m² every 3 weeks with G-CSF support in all cycles. Trastuzumab was initiated concurrently with D and continued for a total of 1 year. Hormonal and radiation therapy were given post CT, as indicated. Formalin-fixed paraffin-embedded tumors were available for 642 patients (64.2%) and were centrally assessed for immunohistochemical subtypes (IHC4; N=526), stromal TILs density by morphology (N=636), as well as stromal and intratumoral cytotoxic CD8+ T cell numbers (N=554). TILs and CD8+ were assessed as continuous variables for associations and as 10% increments for outcome.

Results: In total, 901/1,000 pts (90.1%) completed 8 cycles of CT. Severe (grade III-IV) toxicities included neutropenia (5.6%), leucopenia (3.6%), lymphopenia (2.1%), hand-foot syndrome (2.1%), and hepatotoxicity (1.8%). Febrile neutropenia occurred in 1.6% of the patients. The 5-year DFS and OS rates were 89.5% and 93.1%, respectively. Luminal A tumors were classified in 26.2%, Luminal B in 35.2%, luminal HER2 in 9.5%; HER2-enriched in 7.2%; and, triple-negative (TNBC) in 21.9% of informative patients. Among subtypes, stromal TILs density was higher in HER2-enriched and TNBC (p<0.001); intratumoral CD8+ values were higher in TNBC (p<0.001); and, stromal CD8+ were higher in HER2-enriched (p=0.034). In all patients, TILs density and intratumoral CD8+ cell numbers were not associated with DFS and OS, while increased stromal CD8+ were marginally associated with prolonged DFS (HR=0.98, 95% CI 0.96-1.00, p=0.066). Adjusted for histological grade, menopausal, ER/PgR and nodal status, higher stromal CD8+ were associated with prolonged DFS (HR=0.98, 95% CI 0.96-1.00, p=0.043). In TNBC, higher stromal TILs density conferred prolonged DFS (HR=0.97, 95% CI 0.94-0.99, p=0.029), which retained its prognostic significance in multivariate analysis (HR=0.97, 95% CI 0.94-1.00, p=0.049).

Conclusions: In this study, dds-CT was well tolerated and active in patients with EBC. We confirm the presence of morphologically assessed higher TILs density, and of higher cytotoxic CD8+ T cell numbers in hormone receptor negative EBC, as well as the favorable prognostic impact of higher stromal TILs density in TNBC. In comparison to stromal TILs density, higher stromal CD8+ may confer favorable prognosis irrespectively of EBC subtype. Stromal CD8+ seems to be a marker worth further standardizing for reporting on immune cell infiltrates in EBC.
Invasive micropapillary carcinoma had no difference in prognosis compared with invasive ductal carcinoma: A propensity-matched analysis

Shuang Hao¹,², Yuan-Yuan Zhao¹,², Jin-Juan Peng³, Wen-Tao Yang¹,², Fei Ren¹,², Ke-Da Yu¹,² and Zhi-Ming Shao¹,²,⁴. ¹Cancer Center and Cancer Institute, Shanghai Medical College, Fudan University, Shanghai, China; ²Shanghai Medical College, Fudan University, Shanghai, China; ³The Fourth People's Hospital of Zhenjiang, Zhenjiang, China and ⁴Institutes of Biomedical Science, Fudan University, Shanghai, China.

Background: Invasive micropapillary carcinoma (IMPC) is a rare histopathological variant of breast carcinoma and usually performs poor clinical characteristics, such as high tendency of lymph nodes metastases. But whether it has worse prognosis than invasive ductal carcinoma (IDC) is still controversial nowadays. We conducted this retrospective study to figure out the prognostic difference between IMPC and IDC, then guide therapy of IMPC ultimately.

Methods: In this study, we analyzed 327 cases of IMPC patients and 4979 cases of IDC who underwent primary resection in our institution during 2008 to 2012. By using propensity score matching, two groups were matched at a ratio of 1:1 by age, tumor size, nodal status, hormone and HER2 status to demonstrate the difference of prognosis assessed by Kaplan-Meier estimates and Cox regression analysis.

Result: After a mean follow-up of 52 months, we established the IMPC group and figured out 324 IDC patients from the control group by propensity score matching (3 IMPC patients were canceled because of data missing). The result of survival analysis indicated that women diagnosed with IMPC had no significant reduced overall survival (OS) (p = 0.752) and disease-free survival (DFS) (p = 0.578) compared with women with IDC. Multivariate Cox regression analysis revealed that IMPC was not found as an independent prognostic factor for DFS (hazard ratio [HR] = 0.858; 95% confidential interval [CI], 0.419-1.757) or OS (HR = 0.720; 95%CI, 0.353-1.469).

Conclusion: The consequence of survival analysis manifested that there was no statistically significant difference between 2 groups, and elucidated proactive or radical clinical therapy was unnecessary.
Locoregional recurrence in invasive breast cancer and association with tumor infiltrating leukocyte (TIL) presence

Casey L Liveringhouse¹, George D Grass², Nicholas B Figura², Matthew N Mills², Jacob D Purcell², Sean R Rosensweig¹, Peter W Blumencranz³, Kathleen G Allen³, Kamran A Ahmed³, Louis B Harrison², Javier F Torres-Roca², Timothy J Robinson² and Roberto Diaz². ¹University of South Florida College of Medicine, Tampa, FL; ²H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL and ³Morton Plant Hospital, Clearwater, FL.

Background:
The presence of TILs has been correlated with clinical outcomes and response to therapy in breast cancer. However, evaluation of TILs in breast cancer has largely been based on pathologic examination of tumor samples. Here, we report the relationship between invasive breast cancer locoregional recurrence (LRR) and the presence of TILs estimated by transcriptomic analysis with the deconvolution algorithm CIBERSORT.

Methods:
 Patients were identified from an IRB-approved prospective tissue collection protocol at one academic institution and two community hospitals. 526 primary breast tumor samples were identified and gene expression profiling was assessed with high density Affymetrix microarray chips. Proportions of 22 different TIL types in samples were inferred based on the CIBERSORT algorithm, which uses gene expression data to estimate TIL presence. TIL presence was determined by dichotomization at the level of the first quartile among all samples (>Q1=TIL presence). Patient characteristics and clinical outcomes were obtained by chart review. Time to event analysis was performed using Kaplan Meier (KM) estimates and the log-rank test. Associations between patient factors, tumor factors, TIL presence, and LRR were explored with univariable (UVA) and multivariable (MVA) analyses. Factors significant on UVA (p<0.10) were included on MVA. P<0.05 was considered statistically significant on MVA.

Results:
526 women with invasive breast cancer and available genomic profiling were retrospectively identified for analysis. Median age at diagnosis was 58 years. 70% of tumors were Stage I-II. 69% were luminal subtypes and 17% were triple negative. 37% received mastectomy, 25% received mastectomy + radiation, and 32% received breast conserving therapy. 64% received chemotherapy, and 62% received hormonal therapy. Median follow-up was 74.4 months. There were 61 LRRs. We found significant differences in time to LRR when comparing presence vs. no presence of resting memory CD4+ T-cells (RMCD4+) (p=0.01), activated natural killer cells (ANK) (p=0.003), and neutrophils (PMNs) (p=0.03). On UVA, factors associated with LRR were patient age at diagnosis (p=0.009), pathologic T stage (p=0.045), Estrogen receptor status (p=0.03), biologic subtype (p=0.01), lymphovascular invasion (LVI) (p=0.018), positive margins (p=0.0001), receipt of hormonal therapy (0.014), and presence of tumor infiltrating RMCD4+ (p=0.012), ANK (p=0.0004), and PMNs (p=0.033). On MVA, factors remaining significant were LVI (HR 2.16 CI 1.13-4.13, p=0.011), positive margins (HR 4.36 CI 1.57-12.11, p=0.018), receipt of hormonal therapy (HR 0.31 CI 0.12-0.77, p=0.042), and presence of RMCD4+ (HR 0.48 CI 0.26-0.88, p=0.017), ANK (HR 0.43 CI 0.23-0.83, p=0.012), and PMNs (HR 2.15 CI 1.02-4.53, p=0.043).

Conclusion:
In this study of 526 women with invasive breast cancer, we identified that enrichment of certain TILs is associated with LRR. These results suggest genomic-based assays of TIL presence may be useful to predict LRR in invasive breast cancer.
Validation of the AJCC eighth edition prognostic stage compared with the anatomic stage for breast cancer with a Japanese single-institutional cohort

Hiromi Miyamoto1, Chiaki Saita1, Mai Onishi1, Risa Goto1, Naoko Iwamoto1, Yayoi Honda1 and Tomoyuki Aruga1. 1Tokyo Metropolitan Cancer and Infectious Disease Center Komagome Hospital, Tokyo, Japan.

**Background:** The American Joint Committee for Cancer (AJCC) 8th edition cancer staging system for breast cancer incorporated biologic factors in addition to the 7th edition anatomic stage. We analyzed how the new AJCC 8th edition prognostic stage refined its stratification compared with the anatomic stage.

**Methods:** We reviewed the data of 4,134 patients with stage I to III breast cancer who underwent surgery at Tokyo Metropolitan Komagome Hospital between 2000 and 2016. The anatomic stage and prognostic stage were re-staged according to the AJCC 8th edition staging manual. Patients who received neoadjuvant chemotherapy or had bilateral breast cancer and those with unknown clinicopathologic factors were excluded. The 21-gene Oncotype DX breast recurrence score was not used for staging in this study.

**Results:** A total of 2,469 patients with a median follow-up of 4.7 years (range 0.1-15.5 years) were identified. According to the anatomic stage, there were 1,259 patients of stage IA, 132 of IB, 591 of IIA, 206 of IIB, 130 of IIIA, 14 of IIIB and 73 of IIIC. According to the prognostic stage, there were 1,610 patients of stage IA, 331 of IB, 236 of IIA, 73 of IIB, 85 of IIIA, 43 of IIIB and 27 of IIIC. Sixty-four patients (2.6%) could not be assigned using the new staging system for the presence of micrometastases in lymph nodes with tumors larger than 2 cm. The 5-year disease-free survival (DFS) rates according to the anatomic stage were 97.4% for stage IA, 97.1% for IB, 95.8% for IIA, 86.5% for IIB, 77.9% for IIIA, 49.2% for IIIB and 54.9% for IIIC. According to the prognostic stage, the 5-year DFS rates were 97.9% for stage IA, 92.9% for IB, 91.2% for IIA, 79.8% for IIB, 67.4% for IIIA, 53.3% for IIIB and 38.7% for IIIC. Compared with the AJCC anatomic stage, the prognostic stage was increased in 148 patients (6.2%) and decreased in 808 patients (32.8%). For those in whom the stage changed, the change was by one stage up or down in 463 (19.3%), by 2 stages up or down in 401 (16.7%) and by 3 stages up or down in 92 (3.8%). Of the 1,842 patients with hormone receptor (HR)-positive and human epidermal growth factor 2 (HER2)-negative (HR+/HER2-) disease, 40.5% (745/1842) of cases were downstaged, and 0.7% (1/1842) were upstaged.

**Discussion:** The AJCC 8th edition prognostic staging system provided more refined stratification than the anatomic stage. In the Japanese cohort, the proportion of the downstaging rate was higher than the upstaging rate, and the prognostic evaluation of HR+ patients in particular was improved.
Expression score (Escore) for the prediction of likelihood of recurrence of DCIS

Sunil S Badve¹, Sanghee Cho², Yesim Gokmen-Polar¹, Maria Zavodszyk², Yunxia Sui², C Chadwick², Puay Hoon Tan³, Michael Gerdes³, Adrian L Harris⁴ and Fiona Ginty². ¹Indiana University, Indianapolis, IN; ²GE Global Research Center, Niskayuna, NY; ³Singapore General Hospital, Singapore, Singapore and ⁴Oxford University, Oxford, United Kingdom.

Background: Ductal carcinoma in situ (DCIS) accounts for at least 20% of breast cancers. Factors associated with recurrence of DCIS or progression to invasive carcinoma are not well delineated. The goals of the current study were to profile the epithelial cells using the GE Cell DIVE™ immuno-fluorescent based analyses. This was coupled with semi-automated algorithms to characterize the inter-relationships between cell populations and likelihood of recurrence.

Patients and Methods: A TMA-based (total 8 TMAs) cohort of cases of DCIS with and without recurrence was obtained from Oxford University. Recurrence in this cohort was defined as ipsilateral DCIS, ipsilateral invasive, contralateral invasive and metastatic. Analysis for 31 epithelial markers (HER4, CK56, ABCG2, PTEN, S6, CKAE1, PR, ER, NaKATPase, CK19, ALDH1, CK PCK26, cMET, CD44v6, HER2, CDCP1, p53, CK15, COX2, VEGFR2, ABCb1, HTF9C, CD10, MRP4, CEACAM5, EGFR, p21, MRP5, SLC7A5, Ki67, DAPI) was performed on a single FFPE TMA section containing cases of DCIS. Briefly, FFPE sections from TMAs containing DCIS were sequentially (cyclically) stained for the markers. Each cycle entailed staining with 2-3 markers followed by imaging, dye inactivation, and re-staining. DAPI was used for nuclear demarcation and for registration of the images, while S6, pan-cadherin, Na+K+ATPase and pan-cytokeratin were used for epithelial segmentation. K-means clustering followed regression analysis was performed to identify inter-relationships between markers and association with likelihood of recurrence. Log-rank analysis was performed and the relapse-free survival data depicted using Kaplan Meier plots. Escore was developed by logistic regression model, classification model on recurrence.

Results: Filtering of the expression analysis by the quality, specificity, compartment localization and fields entirely composed of DCIS, in addition to availability of clinical data resulted final analysis of 31 markers in 67 cases. Correlation analyses were performed on each of the markers to identify markers that were significantly correlated in univariate analysis. K-means cluster analysis was performed using a set of 4 markers (ER, HER2, SLC7A5 and cMET) to identify 6 clusters. High cMET (cluster 1; low HER2 and SLC7A5) and High ER (low cMET, HER2, SLC7A5; Cluster 5) were associated with low risk of recurrence (p values 0.014 and <0.0001). In contrast, Cluster 2 (High HER2, high SLC7A5, low ER) and Cluster 3 (High HER2, low ER, SLC7A5 and cMET) were associated with increased risk of recurrence (P values 0.038 and 0.076). A regression analysis based algorithm was developed using these markers to calculate a numerical score which could predict likelihood of recurrence. As depicted in the KM plots, the HR for recurrence increases significantly (P-value 2.4E-05; p=0.02 with LOOCV) with increase in expression score (Escore).

Conclusions: We describe the development of an Escore using expression 4 markers to predict likelihood of recurrence. Additional ongoing studies will seek to validate the utility of the Escore in predicting likelihood of recurrence of DCIS and development of invasive carcinomas and comparison with other scoring systems.
Tumor size still impacted prognosis in breast cancer with extensive nodal involvement

Yin Liu¹, Sheng Chen¹, Yizhou Jiang¹, Jiong Wu¹ and Zhimin Shao¹. ¹Shanghai Cancer Center, Fudan University, Shanghai, China.

Background and purpose
Because of screening and early diagnosis, the stage of breast cancer patients has been brought forward earlier when originally diagnosed. Nevertheless, 10-15% breast cancer patients were diagnosed with extensive nodal involvement in US. Although the size of the tumor and the nodal status are the most important prognostic factors, it is believed that nodal status outperformed the tumor size as a prognostic factor. Particularly, when patients have a nodal stage higher than N2 (more than 9 positive lymph nodes), it is well accepted that tumor size lost its prognostic value. Even in the newest AJCC staging system, which included molecular subtype as an important prognostic factor, T1-3N2 patients were still categorized as the same population. So were T1-4N3 ones. So this study aims to investigate the prognostic value of tumor stage (T stage) in patients with extensive nodal involvement and the survival comparison of T4NxM0 and TxN3M0.

Patients and methods
Breast Cancer female patients with 9 or more positive lymph nodes or with T4 tumors were identified in the SEER registry between 2010-2015. The effect of T stage on BCSS (breast cancer specific survival) and the survival comparison of T4NxM0 and TxN3M0 using Kaplan-Meier survival curve method and risk adjusted Cox proportional hazard regression modeling were assessed.

Results
Overall, 21697 women with N2-3 tumors were included from 284073 patients. T stage, Nodal stage (N stage), ER, PR, HER2 and grade were all independent prognostic factors (p<0.001). HR of ER/PR/HER2/grade/N stage were 0.662 (0.595-0.738), 0.488 (0.438-0.543), 0.541 (0.489-0.598), 1.534 (1.293-1.418) and 1.551 (1.435-1.676). Notably, HER2 positivity was correlated with better BCSS, possibly due to the widely adoption of anti-HER2 therapy. Using T1 as reference, HR of T2/T3/T4 were 1.363 (1.200-1.548), 2.092 (1.824-2.399) and 3.497 (3.045-4.017), respectively.

HR: Hazard Ratio; CI: Confidence Interval.

And the same results held true when subgroup analysis according to N stage were conducted. In the two subgroups, that was T1-3N2 and T1-4N3 women, T Stage was also a significant negative prognostic factor independent of ER/PR/HER2/grade. Moreover, 8328 women staged as T4 with different nodal status were also identified from the whole database. When we compared T4Nx with TxN3 head to head, it was found that T4 tumors had worse outcomes than N3 ones, independent of other prognostic factors. If molecular subtype was included in subgroup analysis, we found that the survival could not be distinguished...
between T4 and N3 only in TNBC.

**Conclusions:**
In patients with extensive nodal status, tumor stage is still a prognostic factor, independent of other factors such as ER/PR/HER2/grade. As to patients with T4Nx or TxN3 tumors, T4 tumors have worse outcomes than N3 ones, independent of other prognostic factors. AJCC staging system might be slightly modified due to these outcomes.
Progression-free survival or time to progression in comparative clinical trials of metastatic breast cancer as a potential surrogate for overall survival: A systematic review of 49 trials focusing on breast cancer subtype

Takahiro Tsukioki¹, Naruto Taira¹, Kentaro Sakamaki², Yoko Suzuki¹, Yukiko Kajiwara¹, Minami Hatono¹, Yuko Takahashi¹, Kengo Kawata¹, Mariko Kochi¹, Takayuki Iwamoto¹, Hirokuni Ikeda¹, Tadahiko Shien¹ and Hiroyoshi Doihara¹. ¹Okayama University Hospital, Okayama, Japan and ²The University of Tokyo, Tokyo, Japan.

Background: Overall survival (OS) is the established endpoint to evaluate the effects of drug treatment in comparative clinical trials of metastatic breast cancer. But assessing OS requires long follow-up periods and large sample size, which raise costs and create long delays in the drug approval process. Progression-free survival (PFS) or time to progression (TTP) is considered as a surrogate for OS and is often used as an alternative to OS. In some cancers the two endpoints are highly correlated, but in others they are not. Furthermore, the effect of breast cancer (BC) subtypes on the surrogacy of PFS/TTP for OS has not been completely defined.

Method: A systematic literature review of randomized control trials was conducted to identify studies that reported both the hazard ratio (HR) of PFS/TTP and OS for BC subtypes {i.e. estrogen receptor (ER) positive, HER2 positive, and triple negative (TN)}. The correlation between the HR of PFS/TTP and OS was evaluated using weighted Spearman's rank correlation.

Results: A total of 49 trials (34 phase III trials and 15 phase II trials) were selected for analysis. Among these trials, there were 8 comparison trials between one chemotherapy and another chemotherapy regimen, 18 comparison trials between chemotherapy and chemotherapy plus molecularly-targeted therapy, 9 comparison trials between one endocrine therapy and another endocrine therapy, and 5 comparison trials between endocrine therapy and endocrine therapy plus molecularly-targeted therapy. There were 17 trials reporting the HR of PFS/TTP and OS for ER positive, 16 trials for HER2 positive, and 9 trials for TN BC. Weighted Spearman's rank correlation revealed that coefficient between the HR of PFS/TTP and OS was 0.721(p<.0001) for all trials, 0.873(p<.0001) for ER positive, 0.642(p=0.0055) for HER2 positive, and 0.615(p=0.078) for TN BC.

Conclusion: There was a strong correlation between the HR of PFS/TTP and OS for ER positive BC, and a weak correlation between the HR of PFS/TTP and OS for HER2 positive and TN BC. The validity of using PFS/TTP as an OS surrogate marker was shown for metastatic BC, especially for ER positive BC.
Pre-analytical effects of FFPE extraction methods on targeted and whole transcriptome sequencing assays for endocrine sensitivity in metastatic breast cancer

Michal Marczyk1, Chunxiao Fu2, Rosanna Lau2, Lili Du2, Alex J Trevarton2, Bruno V Sinn3, Rebekah E Gould2, William F Symmans2 and Christos Hatzis1. 1Yale School of Medicine, New Haven, CT; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3Charité Universitätsmedizin Berlin, Berlin, Germany and 4Silesian University of Technology, Gliwice, Poland.

Background: The clinical management of patients with metastatic HR-positive breast cancer is often uncertain due to decreased sensitivity to anti-estrogen therapy over time. Recently, we developed a targeted RNAseq based 18-transcript SET ER/PR assay of endocrine sensitivity from biopsies of metastatic cancer. In this work we assess the effect of pre-analytical factors, specifically RNA extraction methods for FFPE tissue samples, on the reliability of the targeted RNAseq assay.

Methods: FFPE blocks and matched fresh frozen (FF) sections from 12 tumors were collected at MD Anderson Cancer Center. RNA from FFPE slides was extracted in duplicate using three kits (Norgen, Qiagen, Roche), and RNAseq libraries from all samples were prepared using Kapa Total RNAseq kit. Targeted RNA libraries were prepared using droplet-based PCR (RainDance), and also by transcriptome-wide RNAseq for comparison. Reads were mapped to genomic sequence using STAR and expression was quantified using RSEM. Expression data were normalized based on expression of 10 reference genes. The effect of FFPE RNA extraction kit on the reliability of the SET index was assessed using linear mixed effects model (LME) analysis, and agreement with FF was assessed using the concordance correlation coefficient (CCC).

Results: Analysis of the whole transcriptome RNAseq data confirmed minimal 3’-end transcript bias from FFPE samples, irrespective of transcript size or FFPE kit. All 18 genes included in the SET index had high overall concordance between FFPE and FF (median CCC percentile=98.8, range 57.2-99.9 for Norgen; similar for the other two kits) and relatively consistent bias across genes, as estimated by the random effects of the LME model. Furthermore, compared to random 18-gene indices, concordance in the SET index values between FF and FFPE was higher than 99.8% of the random samples, verifying the analytical reliability of the selected genes. For the targeted RNAseq assay, RNA from FFPE extracted with the Norgen kit showed the highest concordance compared to FF (CCC=0.956, 95%CI 0.871-0.985). In general, the analytical variation of SET from FFPE samples was greater than that from FF (1.71-2.71 fold greater), with the lowest variation associated with the Norgen kit. The SET index values from targeted RNAseq for both FF and FFPE samples were consistently lower compared to transcriptome-wide RNAseq but were highly correlated, with the Norgen kit having the highest correlation between targeted and transcriptome-wide RNAseq (rho=0.915).

Conclusions: All three FFPE RNA extraction kits have excellent analytical performance compared to FF samples. The Norgen kit may be marginally better yielding higher concordance with FF and lower analytical variation between replicates. All genes in the SET ER/PR showed very good analytical performance in comparison to random indices and individual genes. Targeted gene RNA sequencing appears very promising as a platform for clinical deployment of quantitative assays, showing only a small (fixable) bias compared to RNAseq.
Gene expression profiling – a decision impact analysis – Decision dependency on OncotypeDX and EndoPredict as a function of oncological work experience

Christian Eichler1,2, Julia Fromme1, Julian Puppe1, Wolfram Malter1, Stefan Paepke2 and Mathias Warm1,3. 1University of Cologne, Cologne, Germany; 2Klinik und Poliklinik für Frauenheilkunde Technische Universität München, Munich, Germany and 3Municipal Hospital of Cologne Holweide Breast Center, Cologne, Germany.

Background: Estimating distant recurrence risk in women with estrogen receptor-positive, human epidermal growth factor receptor 2 (HER2)-negative early breast cancer is still challenging. Oncotype DX and EndoPredict are two competing, gene expression-based tests predicting the likelihood of recurrent disease. We analyzed the difference in oncological decision making with and without the knowledge of gene expression tests.

Methods: We performed a retrospective, analysis including n = 192 patients diagnosed with G2, HR+, Her2- breast cancer between 2011 and 2015 at the Municipal Breast Cancer Centre Cologne, Germany. All 192 patients received an evaluation by OncotypeDX or EndoPredict. An oncological tumor board (TB) with knowledge of these results served as baseline (control group). This baseline was compared to the treatment decision (adjuvant chemotherapy Yes vs. No) reached by oncologists with different experience levels (less than 5 years, between 5 and 15 years and more than 15 years) who were not provided the OncotypeDX or EndoPredict scores. All clinicians had access to clinical as well to histopathological data only.

Results: Within the EndoPredict group no significant decrease between overall TB decision (adjuvant chemotherapy Yes) 48.1% vs. 15+ years = 39.2%, 5-15 years = 39.2% and <5 years = 50.6% group could be shown. Endopredict seemed to overestimate the clinical risk as judged by experienced oncologists. Within the OncotypeDX cohort we were able to find a significant decrease between overall TB decision (chemotherapy Yes) 41.6% vs. 15+ years = 42.5%, 5-15 years = 50.4% and <5 years = 55.6% group (p<0.05). In addition, inexperience led to a significant and numerically greater increase in chemotherapy recommendation. An exploratory subgroup analysis showed significant differences in TB vs oncologist decision for Ki67 >14%, tumor sizes larger than pT2, pN1 and postmenopausal patients for all experience levels.

Conclusions: Overall, results for the EndoPredict group were inconclusive. A significant reduction of chemotherapy recommendation was shown for all experience levels in the Oncotype subgroup however, with a maximum reduction of 14.2%. A subgroup analysis showed that differences in decision making were most likely for patients with a Ki67 >14%, tumor sizes larger than pT2, pN1 and postmenopausal patients. Since these are the patients where the question of pro/contra chemotherapy is most important, it is the opinion of this study group that gene expression testing is especially pertinent for these patients.
Impact of application of AJCC 8th edition on survival rate of the breast cancer

Seonguk Kwon¹, Dae Sung Yoon¹, In Eui Bae¹, Won Jun Choi¹, In Seok Choi¹, Sang Eok Lee¹, Ju Ik Moon¹, Nak Song Sung¹ and Si Min Park¹. ¹Konyang University Hospital, Daejeon, Korea.

Background
The AJCC 8 edition has changed much in comparison with the 7 edition. In addition to TNM stage, biologic marker (ER, PR, HER2), Histologic grade and multigene assays (oncotype Dx.) should be considered for staging. and it has been applied since January 1, 2018.

patients were recategorized and analyzed in order to know if this more complex classification helps to predict the real prognosis of the patients,

Method
We review patients who were diagnosed and treated as breast cancer at Konyang University Hospital. we studied retrospectively 582 patients who were followed up and were able to review.

Stage was classified according to AJCC 7th edition and AJCC 8th edition. survival rate of each stage were analyzed in both editions.

Result
Mean follow up period was 68.6 months. Total 582 patients were included. There was no change in the stage in 257 patients. In 195 patients, the stage was elevated and in 130 patients, the stage was changed down. When classified as AJCC 7th edition, the 5year-survival rate was 95.9% in stage I, 97.9% in stage II, 93.1% in stage III and 89.9% in stage IV. The survival rate of patients in stage I was lower than that of stage II. However, when the AJCC 8th edition was applied, the 5- year survival rate was 97.9% in stage I, 96.9% in stage II, 92.2% in stage III, and 89.9% in stage IV. In 8th edition, the patients in lower stage has higher survival rate.

Conclusion
The prediction of survival rate by stage was more accurate and the difference in survival rate of each stages was more clearly distinguished when The AJCC 8th edition was applied than AJCC 7th edition. AJCC 8th edition was reliable and useful for prediction of prognosis of breast cancer patient.
EndoPredict prognostic signature in pN1mi, estrogen receptor-positive breast cancer: analysis of the French national registry for molecular signatures

1Gustave Roussy, Villejuif, France; 2Centre GF Leclerc, Dijon, France; 3Institut Bergonié, Bordeaux, France; 4Centre Jean-Perrin, Clermont-Ferrand, France; 5Centre Lacassagne, Nice, France; 6Atalante Pathologie, Rennes, France; 7Inopath-Labosud, Montpellier, France; 8Institut Curie, Paris, France; 9AP-HP, Saint-Louis Hospital, Paris, France; 10AP-HP, Molecular Oncology Unit, Saint-Louis Hospital, Paris, France; 11Pharmacogenomics Unit, Institut Curie, Paris, France; 12Centre Eugène Marquis, Rennes, France and 13Institut d'Analyse Génomique Imagenome, Inovie, Montpellier, France.

Background
The EndoPredict (EP) test has been developed and validated for assessing recurrence risk in patients with estrogen receptor (ER)-positive HER2-negative breast cancer (BC). This test is based on the expression of 12 genes (molecular score), combined with clinicopathological criteria (i.e. tumor size and nodal status) (EPclin risk score). For node-positive patients, the weight given to the node status in the EPclin score is similar when considering pN1mi (≤0.2-2mm) or pN1 (>2mm, 1-3 positive lymph nodes).

Our aim was to characterize the EPclin classification of the pN1mi subgroup in the French national registry for molecular signatures in ER+ BC.

Methods
Since April 2016, nine French laboratories using EP test in clinical practice prospectively implement a national registry for molecular prognostic signatures in ER+ BC. We analyzed the pN1mi subgroup with regards to their clinico-pathological characteristics, molecular EP score and EPclin risk score. Using the definition formula of the EPclin score [EPclin=0.35t + 0.64n + 0.28EP, with \( n = 1 \) for pN0, 2 for pN1mi/pN1, 3 for pN2, 4 for pN3], we could calculate a hypothetical EPclin score if the pN1mi had been considered as pN0 [\( n \) factor=1].

Results
By the end of 2017, the database included 1246 EP tests performed in routine practice, including 67 (5.4%) pN1mi. The pN1mi BC were ER+ HER2- (67/67, 100%), invasive carcinoma of no special type in 52/67 (78%), with a median tumor size of 18 mm (range 7-45; pT1c in 40/67). Among these, 22 were classified as EPclin low and 45 as EPclin high, with a median EP score of 6 (range 2-14), a median EPclin score of 3.70 (range 3-6), and a median relapse risk at 10-year of 15%(range 5-73). Most interestingly, 23/67 (34%; i.e. 1.8% of all EP tests performed) pN1mi BC displayed an EPclin score comprised between 3.4 and 4, just above the cut-off value of 3.3: these cases (and only these cases) would have been classified in a different risk category (i.e. EPclin low risk) if the node status would have been considered as negative.

Conclusion
With regards to EndoPredict test in pN1mi BC - and the persistent debate as to whether they should bear the same weight as node-positive (pN1) or negative (pN0) tumors - categorization in the EPclin class is not likely to be impacted by the node factor weight in the vast majority (>65%) of the pN1mi cases and >98% of all patients tested with EP. Only cases with an EPclin between 3.4 and 4 might be impacted.
Prognostic significance of preoperative neutrophil-to-lymphocyte ratio in postmenopausal breast cancer patients

Hideki Ijichi¹, Wakako Tajiri¹, Takanobu Masuda¹, Chinami Koga¹, Junko Tanaka¹, Yoshiaki Nakamura¹, Masahiro Okamoto¹ and Eriko Tokunaga¹. ¹National Hospital Organization Kyushu Cancer Center, 3-1-1 Notame, Minami-ku, Fukuoka, Japan.

Background: Several studies have shown the association between high neutrophil-to-lymphocyte ratio (NLR) and poor prognosis in various cancer types, including breast cancer. On the other hand, menopausal status, which is an important consideration in breast cancer treatment, has been shown to be associated with changes in NLR levels. The purpose of the present study was to clarify the prognostic significance of preoperative NLR, especially in postmenopausal breast cancer patients.

Patients and methods: Between October 2003 and December 2014, 1868 women underwent surgery without neoadjuvant systemic therapy for primary breast cancer in our department. The optimal cutoff value of preoperative NLR was determined using receiver operating characteristic curve analysis. The patients were divided into two groups based on the NLR cutoff value of 3.34: High NLR (NLR value ≥ 3.34) and Low NLR (NLR value < 3.34). Correlations between clinicopathological characteristics and preoperative NLR were analyzed, and relapse-free survival (RFS) and overall survival (OS) were estimated.

Results: Among the 1868 patients, 286 (15.3%) and 1582 (84.7%) patients were classified into High NLR and Low NLR, respectively. Although the patients in High NLR was younger (p=0.0023), there were no significant correlations between NLR and all other prognostic factors, such as tumor size, lymph node status, and histological grade. High NLR was associated with tendency to shorter RFS (p=0.0583) and shorter OS (p=0.0303). In postmenopausal patients (n=1177), significant correlations were observed between High NLR and shorter RFS and OS (p=0.0002 and p=0.0011). However, NLR was not correlated with RFS and OS in premenopausal patients (n=691). Although the postmenopausal patients with relapsed cancer had higher NLR levels than those without relapse (p=0.0252), NLR levels were not correlated with relapse occurrence in premenopausal patients. Both univariate (p=0.0009) and multivariate (p=0.0015) analyses revealed that High NLR as well as larger tumor size, lymph node metastases, and higher histological grade was significantly associated with relapse in postmenopausal patients. Moreover, in postmenopausal patients, subgroup analysis according to cancer subtype revealed that High NLR was correlated with shorter RFS only in patients with hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative breast cancer (p=0.0009), in those without adjuvant chemotherapy (p=0.0034) but not in those with adjuvant chemotherapy.

Conclusion: Elevated preoperative NLR is an independent predictor of poor prognosis in postmenopausal but not premenopausal patients with breast cancer. In postmenopausal patients, adjuvant chemotherapy may improve prognosis in patients with HR-positive/HER2-negative breast cancer, especially in those with elevated preoperative NLR.
Decentralized beta testing of MammaPrint and BluePrint NGS kit at University Hospitals Leuven and Curie Institute Paris

Background
Many countries restrict patient material exchange to central diagnostic laboratories abroad, limiting access to assays like MammaPrint® (MP) and BluePrint® (BP). Both assays are microarray-based, with MP being prognostic for distant recurrence and BP for molecular subtyping of breast cancer (Luminal-, HER2-, and Basal-type). To increase accessibility, decentralization is required with Next Generation Sequencing (NGS) being the preferred testing platform given that most diagnostic laboratories have the technology in place. The aim of this beta testing study is to validate a previously developed and centrally validated MP and BP NGS kit for RNA samples in two large tertiary academic hospitals in Europe.

Patients and Methods
Patients with early breast cancer diagnosed at the Multidisciplinary Breast Center at University Hospitals Leuven and Curie Institute Paris were prospectively included between September 2017 and January 2018. Patients with bilateral breast cancer or presenting with more than 3 positive lymph nodes were excluded. Only patients with invasive ductal and invasive lobular carcinoma were included. Twenty tissue sections were cut from formalin-fixed, paraffin-embedded (FFPE) blocks; 10 tissue sections were analyzed at the local site using the MP and BP NGS kit, and 10 tissue sections were analyzed at Agenda using the same kit and procedure, as well as with the golden standard method (gene expression microarrays). Targeted RNA sequencing of the 70 MP and 80 BP signature genes was performed on Illumina MiSeq instruments. The raw NGS data generated at the local test sites was sent through a secure file transfer protocol server to Agenda for interpretation and comparison with microarray and NGS performed in the Agenda laboratories. We aimed for a minimum concordance rate between MP and BP outcome of 90% between each local site and Agenda's centralized site.

Results
In this study, 116 early breast cancer patients were included (73 from University Hospitals Leuven and 43 from Curie Institute). Out of these patients, 52% were MP Low Risk and 48% MP High Risk according to microarray. The patients had a BP luminal, HER2 or basal subtype in respectively 83%, 9% and 8%. Concordance between MP microarray obtained from Agenda and MP NGS obtained from the local sites was 91.4%. Concordance between MP High and Low Risk classification between NGS Leuven versus NGS Agenda was 92.1% and between NGS Curie versus NGS Agenda 95.3%. For BP subtype outcomes, the results from microarray versus NGS for all patients combined from both local sites gave a 98.3% concordance and NGS Agenda versus NGS from each local site gave a 100% concordance.

Conclusion
The MP and BP NGS kit was successfully validated in a decentralized setting, showing high concordance between results obtained at three different sites. There was a clear benefit of having well-trained NGS experienced diagnostic technical teams. The MP and BP NGS kit the first FFPE targeted RNA sequencing based multigene signature for breast cancer care, will provide a high and equal standard of MP and BP gene expression testing for breast cancer in a decentralized setting.
Validation of different prognostic scores in breast cancer patients with brain metastases of the BMBC registry (GBG-79)

Background
The incidence of brain metastases from breast cancer is increasing and treatment is a major challenge. Different scores were developed to estimate the prognosis of patients with brain metastases by objective criteria. Sperduto et al. established the disease-specific breast-graded prognostic assessment (GPA) score in 400 breast cancer patients which includes age, performance status and tumor subtype. It has been described that the Breast-GPA best identifies patients with bad prognosis (Laakmann et al. 2016). Aim of this analysis was to validate the Breast-GPA in a large cohort of breast cancer patients with brain metastases.

Materials and methods
Data of 613 breast cancer patients from the Brain Metastases in Breast Cancer (BMBC) registry treated in 80 different clinical German institutions between 2000 and 2016 was analyzed.

Results
135 patients (22%) had a triple-negative, 199 (32%) a luminal-like und 279 (46%) a HER2-positive primary breast cancer. At diagnosis of brain metastases most patients had a good Karnofsky performance status (100%: 14.4%, 80-90%: 44.7%, 60-70%: 28.9%, 40-50%: 9.0%, 10-30%: 3.1%). Median age of patients was 56 years (22-90 years).

Median survival in the overall cohort was 7.1 months (95% CI 6.2-7.8 months).

Distribution of GPA scores was: 0-1: 11.9% (n=73), 1.5-2: 22.3% (n=137), 2.5-3: 47.8% (n=293), 3.5-4: 18% (n=110).

Median overall survival within the GPA-subgroups varied between 2.4 (CI95% 2.0 - 3.4); 4.8 (3.6 - 6.9); 9.2 (7.2 - 11.3) and 12.3 (8.9 - 18.0) months and, thus, was significantly shorter compared with the times published by Sperduto et al. (3.4; 7.7; 15.1 und 25.3 months).

Conclusions
The breast-GPA is easy to calculate in clinical routine, allows to assess patients’ prognosis objectively and can facilitate making therapeutic decisions. However, absolute survival may differ from the originally published cohort in other settings.
The 21-gene Recurrence® (RS) Score assay in estrogen receptor positive node negative breast cancer: Real-world chemotherapy usage and patient characteristics within the intermediate and high-risk RS category

Dan Le¹, Stephen Chia¹, Christine Simmons¹, Caroline Speers¹, Lovedeep Gondara¹, Alan Nichol¹, Caroline Lohrisch¹ and Karen A Gelmon¹. ¹BC Cancer, Vancouver, BC, Canada and ²University of British Columbia, Vancouver, BC, Canada.

Background: The Oncotype Dx, a 21-gene recurrence score (RS) assay, has been validated as a prognostic tool in early-stage, hormone receptor-positive, HER2-negative breast cancer. A RS of ≥31 is predictive for chemotherapy benefit. However, it has not been clearly established whether more intensive chemotherapy regimens for these patients provide further benefit and whether higher RS stratifications (≥41) influence treatment decisions.

Methods: From the prospective British Columbia (BC) Breast Cancer Outcomes Unit database, we identified patients with N0 disease who received Oncotype Dx testing from May 2010 to December 2016. Patients with previous or synchronous breast cancer, and patients treated with neoadjuvant chemotherapy were excluded. Groups were defined that had an Oncotype Dx RS of 31-40 and ≥41. Demographic characteristics and type of chemotherapy received were collected. Additional subgroups were defined for patients who had a RS of 21-25 and who were ≤50 years old and > 50 years old.

Results: We identified 1,202 patients who received Oncotype Dx testing over the time period studied, with 14.8% (n=178) having a RS of ≥31. Among these high-risk patients, the median age was 58 (range 34-79), 90% received hormonal therapy and 85% received chemotherapy. In this cohort, 46% received docetaxel and cyclophosphamide for 4 cycles and 28% received 3rd generation chemotherapy. The use of 3rd generation chemotherapy in patients with a RS of ≥41 was significantly higher than in patients with RS between 31-40 (39% vs 22%, p = 0.006). Among patients who had a RS of 21-25 and who were ≤50 years old (n = 49), 53% received chemotherapy. Of patients who had a RS of 21-25 and who were > 50 years old (n = 127), 16% received chemotherapy.

Conclusions: Among patients with a RS ≥31, decisions regarding chemotherapy usage were heterogeneous with docetaxel and cyclophosphamide for 4 cycles being the most commonly used regimen. However, in those with a RS ≥41, 3rd generation chemotherapy was preferred. Patients with a RS between 21-25 and who were ≤50 years old received more chemotherapy than patients who were > 50 years old.

Clinical risk prediction models for breast cancer: A review of models developed between 2010 and 2018

Sabine Siesling, Tom Hueting, Barbara Tip, Rob Mentink and Erik Koffijberg. 1Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; 2University of Twente, Enschede, Netherlands and 3Evidencio, Haaksbergen, Netherlands.

Background:
Clinical prediction models provide insight in the probability of a specified event happening based on the personal characteristics of the patient. Predicted probabilities support physicians in tailoring clinical decisions to the patients needs. Throughout the past decades, the amount of developed prediction models has grown, yet the application of these models in daily medical practice falls behind. It is currently uncertain how many prediction models exist to support decision making in breast cancer care and exactly which decisions may be supported using prediction models. This study aimed to identify all developed prediction models on breast cancer care and to assess the clinical applicability of the models in the target breast cancer population.

Methods:
A literature search was performed to identify developed risk prediction models published from January 2010 up to June 2018. Models predicting breast cancer related events were included. Identified models were assessed on the reported transparency and reproducibility and incorporated in the online platform for prediction models: Evidencio. Clinical applicability of the models was assessed using a digital implementation of the Dutch breast cancer guideline called Oncoguide. Models were assigned to location in the guideline where they may support clinical decisions.

Results:
A total of 91 studies describing the development of 142 prediction models were identified. Thorough assessment showed that 31 models were reported in full having the description of all the necessary parameters to reproduce the underlying statistical formula and were incorporated in Evidencio.com. For 95 models the formula could be derived through the presented nomogram, table, or online calculator. The remaining 16 models were lacking information to construct any method to predict the outcome of an individual patient and could therefore not be used in practice.

Conclusion:
A total of 142 prediction models were developed between January 2010 and June 2018. The overall quality of reporting was poor as 111 models were not described transparently. All identified models were assigned to the location in the guideline of which the model may support clinical decision making. Further assessment is necessary on the clinical impact and validity of the models in the Dutch population before implementing them in the guideline.
Lymphatic invasion is an independent risk factor in patients with small node-negative luminal breast cancer

Tomomi Abe¹, Yoshinori Ito¹, Ippei Fukada¹, Tomoko Shibayama¹, Makiko Ono², Takayuki Kobayashi¹, Kokoro Kobayashi¹, Shunji Takahashi², Rie Hori²³, Futoshi Akiyama²³, Takuji Iwase¹, Takayuki Ueno¹ and Shinji Ohno¹. ¹Breast Oncology Center, the Cancer Institute Hospital of the Japanese Foundation for Cancer Research, Tokyo, Japan; ²The Cancer Institute Hospital of the Japanese Foundation for Cancer Research, Tokyo, Japan and ³The Cancer Institute, the Japanese Foundation for Cancer Research, Tokyo, Japan.

[Background]
In patients with node-negative (N0), hormone receptor-positive, human epidermal growth factor receptor (HER2) -negative (luminal) breast cancer, the impact of lymphatic invasion (ly) on the prognosis remains to be clarified.

[Methods]
Among 3,158 patients with primary breast cancers who underwent surgery in our institute from January 2007 to December 2009, we analyzed 1027 N0 luminal invasive breast cancers without preoperative systemic therapy. The luminal breast cancer was defined as hormone receptor-positive (ER of $\geq 10\%$ or PgR of $\geq 10\%$) and HER2-negative (immunohistochemistry: 0, 1+ or FISH: ratio < 2.0) cancer in the postoperative pathological specimen. ly was defined as positive when cancer cell nests were detected within the lymph duct in the whole specimen. N0 was confirmed pathologically by the sentinel lymph node biopsy in all the patients. The Fisher’s exact test was used for comparison between different categories. The distant recurrence rate (DRR) was analyzed using the Kaplan-Meier method and the log-rank test. For multivariate analysis, Cox’s regression analysis was performed.

[Results]
The median follow-up period was 103.8 months (range: 5.6-128.8). Recurrence with distant metastasis occurred in 26 patients (2.5%). There were 5 (0.7%) deaths related to breast cancer. ly was detected in 240 patients (23.4%). In the ly-positive group, the tumor size was larger (p = 0.007), and the nuclear grade (NG) was higher (p < 0.001) than in the ly-negative group. Postoperative endocrine therapy (p < 0.001) and postoperative chemotherapy (p < 0.001) were more frequently employed for patients with ly-positive tumor. The univariate analysis showed that ly positivity (p < 0.001), large tumor size (p < 0.001), high NG (p < 0.001), PgR negativity (p = 0.002) and the history of adjuvant chemotherapy (p < 0.001) were associated with high DRR. In the multivariate analysis, large tumor size (p = 0.007) and PgR negativity (p = 0.015) remained significant. Although positive ly had a risk ratio of 2.2, it was not an independent risk factor. When restricted to T1 tumor (n = 899), the aforementioned factors still showed prognostic value in the univariate analysis, among which ly positivity (p = 0.004) remained significant together with PgR negativity (p = 0.047) in the multivariate analysis. The 8-year DRR was very favorable (0.8%) in patients with ly-negative T1N0 tumor while it was modest (6.6%) in patients with ly-positive T1N0 tumor (p < 0.001). Only 1.3% of the patients had received adjuvant chemotherapy in the ly-negative group while 27% of the patients had in the ly-positive group.

[Conclusion]
Lymphatic invasion was associated with higher DRR although it was not independent in the multivariate analysis among patients with N0 luminal breast cancer. When restricted to patients with T1N0 luminal breast cancer, the presence of ly was independently associated with higher risk of distant recurrence. It suggests that the assessment of ly is clinically more relevant when considering treatment options for small luminal breast cancer.
Prognostication of immune related gene expression in patients with triple negative breast cancer

Ji-Yeon Kim¹, Hae Hyun Jung², Eun Youn Cho¹, Se Kyung Lee¹, Jong Han Yu¹, Jeong Eon Lee¹, Seok Won Kim¹, Seok Jin Nam¹, Yeon Hee Park¹, Jin Seok Ahn¹ and Young-Hyuck Im¹. ¹Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea and ²Biomedical Research Institute, Samsung Medical Center, Seoul, Korea.

Introduction: To date, the role of immunotherapy with check point inhibitors and/or vaccines in the treatment of breast cancer (BC) is still debating, and the main focus of immunotherapy in BC is on triple negative subtype as a target population in many ongoing clinical trials. Translational research into identifying predictive and prognostic immune biomarkers is of particular clinical relevance, but, there are currently no definite prognostic and predictive immune biomarkers in BC, especially in triple negative breast cancer (TNBC). We investigated the expression profiles of immune genes in patients with TNBC to identify the prognostic value of immune genes in search of clinical implications.

Methods: We investigated expression profiles of 770 pan-cancer immune related genes using the nCounter mRNA expression assay (NanoString®) from paraffin-embedded tumor tissues in 200 patients diagnosed as TNBC who received curative surgery at Samsung Medical Center from 2000 to 2004. We analyzed the relationship between stage adjusted level of gene expressions and patients' survival outcomes using Cox regression model.

Results: Of 770 genes, 186 genes were selected from univariate analysis with clinical stage adjustment. In multivariate analysis using Cox regression, expressions of CD1B, CD45, CD53, CT45A1, GTF3C1, IL11RA, IL1RN, LRRN3, MAPK1, NEFL, PRKCE, SPACA3 and RANKL were associated with distant recurrence free survival (p<0.05, respectively). Among these 13 genes, expression of MAPK1, NEFL, CD45, SPACA3 and RANKL were correlated with favorable outcome in terms of distant recurrence free survival (p<0.05, respectively). In terms of overall survival, C3, IL1RL1, IL1RN, IL7 and PRKCE were associated with poor prognosis (p<0.05, respectively) and expression of SAA1 CXCL9 and RANKL resulted in favorable outcome (p<0.05, respectively).

Conclusions: High expression of IL1RN, PRKCE were associated with short distant recurrence free survival and overall survival in patients with TNBCs who received curative surgery. In contrast, RANKL expression resulted in prolonged distant recurrence free survival and overall survival.
Derivation and validation of a novel prediction model in breast phyllodes tumors after surgery

Erwei Song¹, Xue Chao², Yan Nie¹, Xiaoyan Jin¹, Cui Tan³, Junwei Cui³, Hui Hu³ and Herui Yao¹. ¹Sun Yat-sen Memorial Hospital, Guangzhou, Guangdong, China; ²Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China and ³Peking University Shenzhen Hospital, Shenzhen, Guangdong, China.

Aim
This study aimed to develop a nomogram based on clinicopathological features to evaluate the recurrence probability of breast phyllodes tumors following surgery. The criteria for atypia, mitoses, overgrowth, and surgical margin (AMOS) were also validated.

Method
Data from 334 patients with breast phyllodes tumors, who underwent surgical treatment at Sun Yat-sen Memorial Hospital from January 2005 to December 2014, were used to develop a prediction model. Additionally, data of 36 patients from Peking University Shenzhen Hospital and data of 140 patients from Sun Yat-sen University Cancer Center during the same period were used to validate the model. The medical records and tumor slides were retrospectively reviewed. The log-rank and Cox regression tests were used to develop a clinical prediction model of breast phyllodes tumors as well as validating the AMOS criteria. All statistical analyses were performed using R and STATA.

Results
Of all 334 patients included in the study, 224 had benign, 91 had borderline, and 19 had malignant tumors. The local and distant recurrence rate was 17.7%. The 1-, 3-, and 5-year cumulative recurrence-free survival was 98.5%, 97.9%, and 96.8%, respectively. Surgical margin, mitoses, and tumor border were identified as independent risk factors for breast phyllodes tumors. A nomogram was developed based on these three variables. The C-index of internal and external validation was 0.71 and 0.67, respectively. The area under the curve of AMOS criteria was 0.59.

Conclusions
The present study model presented a more concise and objective variables to evaluate the recurrence-free survival of patients after surgery compared with that using the AMOS criteria, which is more appropriate for clinical practice and also allows for a more accurate prediction.
The significance of Oncotype DX recurrence score in $T_{1-2}N_{1}M_{0}$ ER positive HER2 negative breast cancer: An analysis combined with the prognostic stage in the updated AJCC 8th edition

Hongliang Chen¹, Maoli Wang¹, Peng Zhang¹, Mingdi Zhang¹ and Kejin Wu¹. ¹Obstetrics and Gynecology Hospital of Fudan University, Shanghai, China.

**Purpose:** Oncotype DX recurrence score (Oncotype DX RS) is applied in the prognostic stage in $T_{1-2}N_{0}M_{0}$ ER+/HER2- breast cancer. But its significance is unclear in cases with $T_{1-2}N_{1}M_{0}$ ER+/HER2- disease. Our study was to evaluate the prognostic significance of Oncotype DX RS in combination with the prognostic stage in the updated AJCC 8th edition. **Methods:** The Surveillance, Epidemiology, and End Results (SEER) database was searched to identify invasive ductal breast cancer cases in $T_{1-2}N_{1}M_{0}$ stage with ER positive HER2 negative status and Oncotype DX RS diagnosed between 2004 and 2012. Patients with unknown histologic grade or PR status, no or unknown surgery performed, or less than 6 months of follow up were excluded. Patients with RS 0-10, 11-25, >25 were categorized into low risk, midrange risk and high risk groups respectively. Comparisons of the distribution of RS groups among prognostic stages were performed using Pearson's chi-square. Breast cancer-specific survival (BCSS) and overall survival (OS) were estimated using the Kaplan-Meier method and compared across RS groups using the log-rank statistic. Cox models were fitted to compare the association between RS groups, prognostic stages and BCSS or OS after adjusting for other characteristics. **Results:** Altogether 4059 cases were enrolled, which were categorized into prognostic stage IA-IIB (only 357 cases in stage IIB and 35 cases in stage IIIA). More than 60% cases in prognostic stage IA-IIA had their RS in midrange risk group. There were decreasing proportion of low risk RS group and increasing proportion of high risk RS group with the ascending of prognostic stages ($P<0.001$). The median follow up was 59 months. There were significant differences in BCSS and OS among RS groups (log-rank $P<0.001$). In the subgroup analysis, there were also significant differences in BCSS and OS among RS groups in prognostic stages IA-IIA. In the multivariate Cox analysis, the RS group was an independent prognostic factor for BCSS (midrange risk vs. low risk, HR=3.647, 95% CI: 1.124-11.837, $P=0.031$; high risk vs. low risk, HR=15.372, 95% CI: 4.600-51.374, $P<0.001$) and OS (midrange risk vs. low risk, HR=1.718, 95% CI: 1.039-2.840, $P=0.035$; high risk vs. low risk, HR=4.225, 95% CI: 2.462-7.251, $P<0.001$) along with the prognostic stage. **Conclusions:** Oncotype DX RS has prognostic significance in $T_{1-2}N_{1}M_{0}$ ER+/HER2- disease. Further prospective research is warranted.
MammaTyper® – An in vitro quantitative local gene expression test as a predictor of OncotypeDX®- and EndoPredict®-results

Kerstin Eckhoff¹, Juliane Pokorny², Kristin Baumann¹, Sven Perner², Telja Pursche¹ and Achim Rody¹. ¹University Medical Center Schleswig-Holstein, Breast Center, Lübeck, Germany and ²Pathology of the University Hospital Schleswig-Holstein, Campus Lübeck and the Research Center Borstel, Leibniz Lung Center, Lübeck, Germany.

Background:
Risk stratification in early-stage breast cancer patients still remains a clinical challenge. It is well known that expression of ER/PR, HER2 and Ki-67 are valuable prognostic and predictive markers. According to the commonly used St. Gallen classification (2013), breast cancer treatment decisions can be based on four different subtypes (Luminal A-like, Luminal B-like [HER2+/-], HER2 + [non-luminal] and Basal-like). Immunohistochemistry is predominantly used to determine the receptor status, although semi-quantitative analysis shows significant inter-observer variability. Several quantitative gene expression tests – such as Oncotype DX® and EndoPredict® – are available as diagnostic tools but their use is often limited due to financial considerations. MammaTyper® has been shown to be a precise and reproducible biomarker determination tool to investigate the expression of ER/PR, HER2 and Ki-67 and may prove to be a cost efficient quantitative diagnostic tool.

Methods:
This study tested ESR-1, PGR, MKI67 and ERBB2 mRNA-levels by RT-qPCR in 100 FFPT-samples using MammaTyper® kit. The test identified breast cancer subgroups according to St. Gallen classification. RT-qPCR results were correlated to IHC-test results via χ²-Test and to risk groups of Oncotype DX®- (n=55) and EndoPredict®-testing (n=45). Oncotype®-Recurrence Score levels were separated into low (RS <18), intermediate (RS 18-30) and high risk (RS ≥ 31). EndoPredict® EPScore® and EPclin Risk Score® cut off levels defining high and low risk levels were 7.0, respectively 3.3. Linear regression model was performed investigating the prediction of EPScore® and Recurrence Score® via MammaTyper® mRNA-results.

Results:
IHC-testing resulted in 43 Luminal A-like samples (43%) and 57 Luminal B-like [HER2 negative] (57%) tumors. MammaTyper®-based classification showed significant correlation to IHC-based classification (χ²=12.68; p=0.005). EndoPredict®-data showed low-risk levels in 36 patients (80%) and high-risk status in 9 cases (20%). Correlation to mRNA-based St. Gallen-subtypes approved significance (χ²=17.32, p<0.001). In linear regression model only MKI67-mRNA showed independent correlation to EPScore® (p<0.001; R² 0.290)
A total of 34 patients (61.8%) showed low risk, 13 (26.3%) intermediate risk (RS 18-30) and 8 (14.5%) high-risk recurrence score levels (RS≥31) in OncotypeDX®. MammaTyper® results correlated to OncotypeDX® risk-levels (χ²=27.98; p<0.001). In linear regression model mRNA-levels of ESR-1, PGR and MKI67 were significant predictors of OncotypeDX® RS (p-values: p=0.003, p<0.001, p=0.033, R²= 0.602)

Conclusion:
This study shows mRNA-testing is a valid marker to identify breast cancer subtypes. Additionally, MammaTyper® results are significantly correlated to Oncotype DX®- and EndoPredict®-results, indicating it might be an efficient as well as cost effective diagnostic instrument. However a large prospective multicenter study should be performed to prove its diagnostic validity in predicting the most appropriate and effective treatment in early-stage breast cancer.
Young age at diagnosis is associated with worse prognosis in the luminal A breast cancer subtype. A retrospective institutional cohort study

Zhiyang Liu\textsuperscript{1,2}, Zeyad Sahli\textsuperscript{1}, Yongchun Wang\textsuperscript{1}, Antonio C Wolff\textsuperscript{3}, Leslie Cope\textsuperscript{4} and Christopher B Umbricht\textsuperscript{1}. \textsuperscript{1}The Johns Hopkins University School of Medicine, Baltimore, MD; \textsuperscript{2}Qingdao Municipal Hospital (East), Qingdao, China; \textsuperscript{3}Johns Hopkins University School of Medicine, Baltimore, MD and \textsuperscript{4}The Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Breast cancer (BCA) presents with distinct molecular subtypes, each associated with different patterns of relapse, drug sensitivity, and prognosis. Although age at diagnosis is a recognized independent prognostic risk factor, its relative importance among molecular subtypes is not well documented. The aim of this study was to evaluate the prognostic role of age at diagnosis among BCA patients of different immunohistochemical subtypes (LuminalA, LuminalB, Her2, Triple-negative).

Methods: We conducted a retrospective study of women with invasive BCA undergoing surgery at the Johns Hopkins Hospital from January 2000 - December 2016, excluding patients presenting with stage IV breast cancer. Patients were stratified into three age groups: ≤ 40, 41-60, and > 60 years, and multivariable analysis was performed using Cox regression. To explore age-related differences in gene expression, we identified differentially expressed genes (DEG) between age groups among BCA subtypes in the TCGA dataset. Finally, we identified key driver genes within DEG using a weighted gene co-expression network analysis.

Results: Our cohort included 3,524 patients with a median follow-up of 85.1 months. LuminalA breast cancer patients had significantly lower 5-year Disease Free Survival (DFS) and Distant Metastasis-Free Survival (DMFS) in the ≤ 40 year age group compared to the 40-60 year age group (HR=2.69, 95%CI: 1.72 - 4.23 and HR=2.95, 95%CI: 1.78 - 4.90, respectively), while the other molecular subtypes showed no significant association of DFS or DMFS with age. Age was a stronger predictor of 5-year DFS and 5-year DMFS than tumor grade or proliferative index (Ki67) in LuminalA BCA patients, but not other subtypes.

Gene expression data were obtained from 1097 BCA TCGA patients, divided into two groups (≤40y, n=36; >40y, n=455). We identified 374 DEG between ≤40y and >40y LuminalA BCA subsets. The DEG were enriched in 7 pathways, and the WGCNA analysis identified two modules of co-expressed genes. No age group-specific DEG were identified in non-LuminalA subtypes.

Conclusion: Age at diagnosis may be an important prognostic factor in LuminalA BCA and may improve risk stratification and personalized therapy. Prospective studies are needed to further evaluate the prognostic value of age in this subset of BCA patients.
The DCIS score predicts risk of local recurrence risk after breast-conserving surgery more accurately than ER plus HER2

Eileen Rakovitch1,2, Rinku Sutradhar2, Limei Zhou2, Sharon Nofech-Mozes1, Wedad Hanna1 and Lawrence Paszat1,2. 1Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada and 2Institute for Clinical Evaluative Sciences, Toronto, ON, Canada.

Introduction: Improved individual prediction of 10 yr local recurrence (LR) risk following breast-conserving surgery (BCS) for ductal carcinoma in situ (DCIS) is needed to identify women at low risk, for whom radiotherapy (RT) may be omitted. We hypothesized that LR prediction that includes the Oncotype DCIS score (DS) would be more accurate, and would identify more women with very low LR risks compared to models that include estrogen receptor (ER) plus HER2 without the DS.

Methods: Three predictive models of LR (clinicopathological factors (CPF) alone; CPF+ER+HER2; CPF+DS) were developed and compared in 1,102 cases of DCIS for whom complete covariate and outcome data were available. CPFs included age at diagnosis, lesion size, nuclear grade, comedonecrosis, multifocality, and resection margin width. Categorizations of discrete variables and transformations of continuous variables were examined in Cox models; two-way interactions and interactions with time were assessed. Internal validation was performed by bootstrapping. Individual predicted 10-yr LR risks after treatment with BCS alone were computed from covariate values, estimated regression parameters and the estimated baseline survival function. Model performance was assessed by c-statistics and calibration plots.

Results: 863/1,102 (78.3%) women were age >= 50 years at diagnosis. Lesion size was <= 10 mm in 555/1,102 (50.4%). Nuclear grade was low or moderate in 62.4%. Comedonecrosis was present in 22.1%. Multifocality was observed in 25.2%. Post-BCS RT was received by 54.4%. Mean DS = 37.49 (sd 23.29). DS risk category = low in 611/1,102 (55.4%). ER = positive in 1,025 /1,102 (93.0%) cases. HER2 overexpression = positive in 212/1,102 (19.2%), equivocal in 95 / 1,102 (8.6%) and negative in 795 / 1,102 (72.1%) cases. Adjusting for all CPFs, the hazard ratios (HR) for LR per 50-unit increase in DS = 2.00 (95% CI 1.42, 2.83), for ER positive = 0.58 (95% CI 0.36, 0.95) and for HER2 positive = 0.73 (95% CI 0.41, 1.30). The strongest prediction model incorporated CPF+DS. C-statistics for CPF+DS, CPF+ER+HER2, or CPFs alone models were 0.7025, 0.6879, and 0.6825. The CPF+DS model was better calibrated at predicting low (<=10%) individual 10-yr LR risks after BCS alone than models incorporating CPF+ER+HER2 or CPFs alone, evidenced by c-statistics and plots of observed by predicted risks. Specifically, among women age >= 50 with no adverse CPFs, the CPF+DS model identified the greatest proportion of women (62.3%) with predicted 10-year LR risk <= 10% without RT, compared to the CPF+ER+HER2 (50.9%) or CPFs alone (46.5%) models. When applying the prediction equations to similar women as those in the cohort who were treated with RT, the CPF+DS model again identified the greatest proportion of women (44.4%) with a low predicted 10-yr LR risk without RT (for whom RT could have been omitted) compared to the CPF+ER+HER2 model (39.4%) and the CPFs alone model (32.3%).

Conclusion: Individual prediction of LR risk that incorporates the DCIS score plus clinicopathological factors is more accurate than prediction models based on ER plus HER2, and identifies a higher proportion of women with a low predicted risk of LR after BCS alone, for whom radiotherapy may be omitted.
Validation of iPrevent using the prospective family study cohort (ProF-SC)

Kelly-Anne Phillips¹, Yuyan Liao², Ian M Collins³, Richard Buchsbaum⁴, Prue Weideman¹, Adrian Bickerstaffe⁴, Robert J MacInnis⁴, kConFab Investigators¹, Jack Cuzick⁶, Antonis Antoniou⁷, Irene L Andrilis⁸, Esther M John⁹, Mary B Daly¹⁰, Saundra S Buys¹¹, John L Hopper⁴ and Mary Beth Terry². ¹Peter MacCallum Cancer Centre, Melbourne, Australia; ²Columbia University, New York; ³Deakin University, Geelong, Australia; ⁴The University of Melbourne, Melbourne, Australia; ⁵Cancer Council Victoria, Melbourne, Australia; ⁶Queen Mary University of London, London, United Kingdom; ⁷University of Cambridge, Cambridge, United Kingdom; ⁸Lunenfeld-Tanenbaum Research Institute, Sinai Health System, Toronto, Canada; ⁹Stanford University School of Medicine, Stanford; ¹⁰Fox Chase Cancer Center, Philadelphia and ¹¹University of Utah, Salt Lake City.

Background: iPrevent (https://www.petermac.org/iprevent) provides women with highly-tailored risk management information after first estimating their breast cancer (BC) risk using the established risk prediction models, IBIS and BOADICEA. iPrevent has an internal switching algorithm that governs which model is used for each woman, depending on her risk factor data (i.e. LCIS/atypical hyperplasia status, BRCA status, and cancer family history). This study assessed the calibration and discriminatory accuracy of the 10-year BC risk estimates provided by iPrevent. Methods: Subjects were 16,574 women in the ProF-SC, aged 18-70 years and without BC or bilateral mastectomy at recruitment. After 10 years follow-up, 655 women (4%) were diagnosed with invasive BC. A “batch mode” for iPrevent is not available, so the iPrevent-assigned cumulative 10-year invasive BC risks were calculated by entering self-reported risk factors at cohort entry into either the IBIS (10,169 women) or BOADICEA (6,405 women) software packages (according to the iPrevent switching algorithm). To assess calibration, the mean iPrevent-assigned risk was compared with the mean 10-year observed invasive BC incidence, using a chi-squared goodness-of-fit statistic for the whole cohort, and by quartiles of risk. To evaluate discriminatory accuracy, the overall area under the receiver operating characteristic curve (AUC) for the development of invasive BC within 10 years was computed. Data were censored at date of invasive or in situ BC diagnosis, bilateral mastectomy, death, loss to follow-up, or at 10 years of follow-up. Results: For the whole cohort, iPrevent assigned risk was well-calibrated – 690 expected BCs (E) 655 observed (O) (E/O=1.05, 95% CI: 0.98-1.14), although for women in the highest risk quartile, i.e. ≥6% 10-year risk, E/O=1.19, 95% CI: 1.07-1.32. The AUC was 0.70, 95% CI: 0.68-0.72. Conclusions: iPrevent is well calibrated overall and has good discriminatory accuracy for predicting 10-year BC risk, thus justifying its clinical use.
Simulated outcomes of personalized versus guideline-based breast cancer screening

Yiwey Shieh¹, Laura Esserman¹ and Martin Eklund². ¹University of California, San Francisco, San Francisco, CA and ²Karolinska Institutet, Stockholm, Sweden.

Introduction: Personalized screening, or screening tailored to individual breast cancer risk, is being studied as an improvement on the current practice of guideline-based screening. WISDOM (Women Informed to Screen Depending on Measures of Risk) is an ongoing randomized trial comparing personalized to annual screening. To project the efficacy, safety, and cost of personalized screening on a population level, we constructed a simulation model comparing personalized to guideline-based strategies across the outcomes of advanced (Stage IIB+) cancers, false positives, biopsies, and cost.

Methods: Our simulated cohort consisted of 100,000 women aged 40-74 with demographic and risk factor distributions based on the U.S. screening population. We modeled the WISDOM approach to personalized screening where recommendations are based on the results of panel-based mutation testing and 5-year risk estimates from a clinical risk model modified by a polygenic risk score containing 76 genetic variants (SNPs). Simulated women were randomly assigned a clinical and genetic risk profile, which were integrated to generate a 5-year risk estimate. This was then used to assign a starting and stopping age, frequency, and modality (MRI vs. mammogram) of screening. We compared the aggregate outcomes over a 1-year time window between personalized screening and 3 strategies based on U.S. professional society guidelines (Table).

Results: There was no statistically significant difference in advanced cancers between screening strategies (Table). However, the biennial, hybrid, and personalized strategies resulted in fewer false positives and biopsies compared to annual screening, and at lower cost. Though aggregate outcomes between the hybrid and personalized strategies were similar, the average 5-year risk of women assigned to annual screening under the personalized strategy was higher than that of the hybrid strategy, 1.7% vs. 1.2%. Similarly, the average 5-year risk of women assigned to biennial screening was lower under the personalized strategy, 1.1% vs. 1.9%.

Conclusion: Our simulations show that personalized screening results in a similar incidence of advanced cancers as annual screening while reducing false positives, biopsies, and cost. Compared to other guideline-based strategies, personalized screening better allocates screening resources by identifying higher-risk women for more intensive screening, and lower-risk women for less intensive screening.

Associations between clinical factors in v7.02 of the Tyrer-Cuzick model and a SNP-based residual risk score

Elisha R Hughes¹, Eric Rosenthal¹, Brian Morris¹, Susanne Wagner¹, Jerry S Lanchbury¹ and Alexander Gutin¹. ¹Myriad Genetics, Inc., Salt Lake City, UT.

**Background:** Genome-wide association studies (GWAS) have identified common variants, primarily single-nucleotide polymorphisms (SNPs), that individually confer modest risk but together explain a significant proportion of genetic breast cancer (BC) predisposition. GWAS have also demonstrated that SNPs cannot replace family history evaluation: familial BC assessment captures a large magnitude of risk information that is not captured by SNPs. Thus, improved BC risk stratification may be achieved by combining family history assessment with SNP markers. However, to avoid double-counting shared risk information, familial and/or SNP-based risks must be adjusted for confounding.

Additional clinical and biological factors that contribute to BC risk are included in version 7.02 of the Tyrer-Cuzick model. These include height; weight; BMI; age of menarche; parity and age of first childbirth; menopausal status and age of onset; and use of hormonal replacement therapy (HRT). Confounding of SNPs with these factors is not well understood. Here we present an analysis of associations between an 86-SNP Residual Risk Score (RRS) and factors included in version 7.02 of the Tyrer-Cuzick model.

**Methods:** De-identified clinical records and genotypes were collected from a consecutive series of patients referred for hereditary cancer testing with a multigene panel. Study subjects included unaffected women age 18-84 who reported European ancestry and tested negative for mutations in 11 genes associated with BC (BRCA1, BRCA2, TP53, PTEN, STK11, CDH1, PALB2, CHEK2, ATM, NBN, BARD1). For each risk factor, we constructed a univariate linear regression model with RRS as the dependent variable and the clinical factor as the independent variable. From these models, we examined regression coefficients, p-values based on F-statistics, and Pearson correlation coefficients. Scatterplots and boxplots were used to visually assess associations. All analyses were conducted using R version 3.4.4. P-values were reported as two-sided with no corrections for multiple testing.

**Results:** 5,489 patients met the study selection criteria. The median age at hereditary cancer testing was 42 years. Nearly one third (33.1%) of women reported a BC diagnosis in a first degree relative. The RRS was significantly associated with familial BC (p<10^{-08}). We observed marginal evidence of association between the RRS and HRT use (p=0.04). However, this association would not survive a multiple testing correction, and was not significant after multivariate adjustment for family cancer history. We found no evidence for association of the RRS with height, weight, BMI, menopausal stage, age of menarche, age of menopause, duration of menarche, parity, age of first live birth, HRT type, or HRT length of use.

**Conclusions:** The RRS is largely independent from the non-familial risk factors in version 7.02 of the Tyrer-Cuzick model, but is significantly associated with BC family history. Risk assessment based on Tyrer-Cuzick and SNPs must be adjusted for confounding to avoid double-counting familial risk.
Analyzing the changes in the HR+/HER2- metastatic breast cancer (mBC) landscape since the arrival of CDK4/6 inhibitors with machine learning and visual analytics

Denise Meade¹, Sharon Hensley Alford¹, Shilpa Mahatma¹, Elisabetta Malangone-Monaco¹, Luke Boulanger¹, Joseph Tkacz¹, Stuart J Turner², Siqi Chen², Stephanie Manson², Susana Mejia², Italo Buleje¹, Piyush Madan¹, Gilwan Kim¹, Robert Fowler¹ and Abul Basar². ¹IBM Watson Health, Cambridge, MA and ²Novartis Pharmaceuticals Corporation, East Hanover, NJ.

BACKGROUND: The real-world impact of CDK4/6 inhibitor use on HR+/HER2- mBC treatment sequencing, treatment response, and therapeutic utilization is limited. This study sought to describe treatment sequencing and response pre- and post-FDA approval of CDK4/6 inhibitors by conducting a traditional observational study approach and supplementing with a machine-learning methodology.

METHODS: Female patients ≥18yrs were identified in the MarketScan Commercial and Medicare Supplement databases with continuous enrollment for at least 12 months pre-index, ≥2 medical claims for a BC diagnosis and ≥2 medical claims for metastatic disease (earliest=index date), and who had no treatment at any time with HER2 targeted therapy. Patients were excluded if they had received CDK4/6 or everolimus treatment prior to index. Treatment was stratified by line of therapy pre- and post- first CDK4/6 approval (February 3, 2015). We identified treatment patterns with standard distributions and visual analytics. Response to therapy and utilization was analyzed with prediction models and IBM Watson® machine learning population comparison models.

RESULTS: A total of 19,558 patients were eligible for the study with a mean age at diagnosis of mBC of 62 (SD 13). Prior to first CDK4/6 inhibitor approval, anastrazole and letrozole monotherapies were most likely to be identified as both first and second line treatment. Following approval of the first CDK4/6 inhibitor in 2015, CDK4/6 inhibitors were observed as a first line treatment in 25% of patients, and as second line treatment in 24% of patients. Of patients diagnosed following the first CDK4/6 inhibitor approval, 44% of patients were exposed to endocrine therapy and 10% were exposed to chemotherapy in the pre-index period. Patients receiving CDK4/6 inhibitors in combination with endocrine therapy as first line treatment were observed to have a longer progression free survival time than patients receiving endocrine monotherapy. Visual analytics demonstrate a large variation in treatment sequencing, especially after first line therapy. Machine learning and prediction models identified a strong secular bias in the use of CDK4/6 and a signal for improved treatment response in patients with no exposure to endocrine therapies in the pre-index period.

CONCLUSIONS: The mBC treatment landscape has changed significantly with the introduction of CDK4/6 inhibitors, which may be expected to impact long-term outcomes. Visual analytics and machine learning approaches can improve clinical insight. These approaches can help with identifying patient and clinical characteristics that predict response and utilization as well as appropriate treatment selections across lines of therapy.
Higher risk of metachronous contralateral breast cancer in patients with invasive lobular breast cancer

Delal Akdeniz1,2, Iris Kramer2, Carolien HM van Deurzen3, Michael Schaapveld2, Pieter J Westenend4, Adri C Voogd5,6, Agnes Jager1, Ewout W Steyerberg3,7, Stefan Sleijfer1, Marjanka K Schmidt2 and Maartje J Hooning1. 1Erasmus MC Cancer Institute, Rotterdam, Netherlands; 2Netherlands Cancer Institute, Amsterdam, Netherlands; 3Erasmus MC, Rotterdam, Netherlands; 4Albert Schweitzer Hospital, Dordrecht, Netherlands; 5Netherlands Comprehensive Cancer Organization (IKNL), Utrecht, Netherlands; 6Maastricht University, Maastricht, Netherlands and 7Leiden University Medical Center, Leiden, Netherlands.

Background: Risk of metachronous contralateral breast cancer (CBC) is an important health issue in primary breast cancer (PBC) survivors. Individualized CBC risk prediction can help identify patients at high or low risk who may or may not benefit from additional surveillance and treatment. For lobular PBC, inconsistent results have been reported on an association with increased risk of CBC. We investigated CBC risk in lobular versus ductal PBC using a large nationwide dataset and taking into account age at PBC and (neo-)adjuvant systemic therapy effects.

Patients and Methods: We selected women diagnosed between 2003 and 2010 with early invasive lobular, lobular mixed with other types, or ductal PBC from the Netherlands Cancer Registry. Categorical and continuous characteristics between the 3 groups were compared using the chi-square statistics and the Kruskal-Wallis test, respectively. Competing risk analyses were applied to determine CBC incidence. Multivariable subdistribution hazard ratios (SHRs) were adjusted for primary tumor stage, age at PBC diagnosis, radiotherapy, (neo-)adjuvant chemotherapy and endocrine therapy.

Results: We selected 74,373 women aged >18 years with lobular (n=8,903), lobular mixed (n=3,512), and ductal (n=62,230) PBC. Women with lobular PBC were older at diagnosis than women with lobular mixed or ductal PBC (61 vs. 58 vs. 58 years, respectively), more often had ER-positive PBC (95.7% vs. 94.1% vs. 79.6%) and were more often systemically treated with only endocrine therapy (30.7% vs. 24.9% vs. 15.4%), while less often treated with only chemotherapy (4.2% vs. 5.3% vs. 15.4%). Ten-year cumulative CBC incidences in women with lobular, lobular mixed or ductal PBC were 3.2%, 3.6% and 2.8% when treated with systemic therapy (chemotherapy and/or endocrine therapy) and 6.6%, 7.7% and 5.6% without systemic therapy, respectively. Multivariable SHRs were 1.19 (95% CI: 1.05-1.34) for lobular and 1.39 (95% CI: 1.17-1.65) for lobular mixed versus ductal PBC; for women <50 years, risk differences were larger: 1.60 (95% CI: 1.26-2.05) and 1.43 (95% CI: 1.00-2.06), respectively.

Conclusion: Lobular histology and lobular mixed histology are independent risk factors for CBC development, and should be considered as prognostic factors when refining CBC risk prediction models.
Shared-patient physician networks and their impact on the uptake of genomic testing in early-stage breast cancer

Jason Rotter¹, Lauren Wilson¹, Melissa Greiner¹, Craig Pollack² and Michaela Dinan¹. ¹Duke University School of Medicine, Durham, NC and ²Johns Hopkins School of Medicine, Baltimore, MD.

Background: Oncotype DX (ODX) or 21-gene recurrence score genomic testing is used to stratify risk and determine appropriate treatment in women with early-stage breast cancer (BC). Diffusion of ODX by way of physician networks has not been studied.

Objective: To determine the association between physician network connections, defined by shared patients, and the use of ODX testing.

Methods: SEER-Medicare claims from 2008-2012 were used to identify a cohort of woman with a diagnosis of BC from registry/ICD codes, continuously enrolled in Medicare fee-for-service Part A and B one year prior to and one year following diagnosis. We identify receipt of ODX from the associated CPT code, claim reimbursement, and performing NPI. To look at the influence of network connections on ODX use, we split the study into two time periods: early adoption from 2008-2009, and late from 2010-2012. Medical oncologists with a BC-related claim in the cohort above, and any rendered BC-related service are considered ‘connected’ if they shared two or more BC patients. Analyses describe these connections and explore the association between connectedness to an early adopting medical oncologist and ODX use in parallel physician and patient-level analyses using generalized linear mixed models with a hospital referral region-specific random effect. Models control for physician and patient-level characteristics where applicable.

Results: 24,463 women met study criteria; 12,874 were diagnosed with BC in the early adoption time period (1,790 received ODX) and 11,589 were diagnosed in the late period (2,334 received ODX). 2,073 medical oncologists treated these patients from 2008-2009. The mean number of BC patients treated per medical oncologist was 86.8 during the early adoption period, and medical oncologists had a median number of peer connections of 11 (IQR: 7-18). Early adopting medical oncologists had higher numbers of peer connections and higher average patient counts than non-early adopters. A higher percentage of female medical oncologists were early adopters (39%) then male medical oncologists (33%) (p<0.02). Among non-early adopting oncologists, peer connection to at least two early adopting providers in 2008-2009 is associated with a 3.2 (95% CI: 2.0-4.9) times increase in the odds of ordering ODX in 2010-2012 after adjustment for physician gender and time in practice. In patient-level models with controls for physician and patient characteristics, seeing a medical oncologist with connections to at least two early adopting physicians is associated with a 1.6 times (95% CI: 1.1-2.2) increase in the odds of receiving ODX testing in 2010-2012.

Conclusions: We observe a positive adjusted association between connectedness to an early-adopting physician and ODX prescribing/use in both physician-level and patient-level analyses. These results suggest that provider networks may help diffuse new technologies, and that BC genomic testing is likely to be an area of shared practices between providers. Efforts to increase testing, where appropriate, may benefit from a range of peer-to-peer connection strategies.
Association between socioeconomic factors at diagnosis and survival in non-metastatic breast cancer: A population-based study

Peng Ji\textsuperscript{1,2}, Yue Gong\textsuperscript{1,2}, Xin Hu\textsuperscript{1}, Digen Hong\textsuperscript{1} and Zhi-Ming Shao\textsuperscript{1,2,3}. \textsuperscript{1}Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Fudan University, Shanghai, China; \textsuperscript{2}Shanghai Medical College, Fudan University, Shanghai, China and \textsuperscript{3}Institutes of Biomedical Science, Fudan University, Shanghai, China.

Background: Breast cancer is a severe public health problem for women worldwide. Race disparities and regional disparities are documented regarding incidence, mortality, and survival of breast cancer patients. However, the associations between socioeconomic status and survival outcomes of breast cancer remain unclear and require a comprehensive large-scale investigation of specific socioeconomic factors. Furthermore, no model has included both histological and socioeconomic factors together to predict survival of breast cancer. In this study, we sought to develop nomograms to predict overall survival (OS) and breast cancer-specific survival (BCSS) with consideration of socioeconomic factors for non-metastasis breast cancer.

Methods: We included a total of 274,108 female patients, diagnosed with malignant breast cancer between 2007 and 2014 from the Surveillance, Epidemiology, and End Results (SEER) database. Socioeconomic factors involving marital status, insurance status, residence, median household income, poverty rate, unemployment rate and education level were included in the analysis. OS and BCSS were evaluated with log-rank tests and Kaplan-Meier estimates. We identified and integrated significant prognostic factors for OS and BCSS using univariate and multivariate Cox regression analysis to construct nomograms. Calibration plots and concordance indexes were used to evaluate the accuracy and discrimination of the models.

Results: Among different age subgroups, insured patients were more likely to have better survival than uninsured patients or patients with Medicaid ($P<0.001$), and especially for patients who were aged 18 to 35 years old at diagnosis, uninsured patients associated with poor BCSS than Medicaid patients ($P<0.05$). Through multivariate analysis, we found non-Hispanic black patients experienced worst survival compared with the White and other races ($P<0.001$). Interestingly, married (vs. single vs. separated/divorced/widowed; $P<0.001$) and insured (vs. Medicaid vs. uninsured; $P<0.001$) patients had a better prognosis. Living in the non-metro area increased the risk of death (hazard ratio [HR], 1.084, $P<0.05$). Furthermore, living in counties with higher median household income (>US $72,800) had favorable impacts on OS (HR 0.843, $P<0.001$). Four and five socioeconomic factors were involved in constructing the nomograms for 3 years-, 5 years- and 7 years- OS and BCSS, respectively. The C-indexes of the final nomograms were higher than those of the TNM staging system for predicting OS (0.776 vs 0.678; $P<0.001$) and BCSS (0.842 vs 0.776; $P<0.001$), respectively. The performance of the nomograms for predicting OS was significantly lower when excluding the socioeconomic factors ($P<0.001$).

Conclusion: Some certain socioeconomic factors (i.e., marital status, insurance status, median household income, and residence) play essential roles in predicting survival of non-metastasis breast cancer. We constructed and validated nomograms including socioeconomic factors to provide more comprehensive and realistic survival estimation. Besides, these findings may highlight the importance of developing health-related policies and the necessity of targeted social support-based interventions for those high-risk patients.
Association of bilateral oophorectomy with sarcopenia and sarcopenic obesity in a diverse, nationally representative sample of U.S. women

Pritesh S Karia1, Corinne E Joshu1 and Kala Visvanathan1. 1Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

Background: Sarcopenia (low muscle mass) and sarcopenic obesity (SO; low muscle mass with high body fat) have been linked to physical disability, poor quality of life, and mortality in older adults. We have previously demonstrated an association between early bilateral oophorectomy and increased body fat. Studies have also indicated that declines in circulating levels of estrogen and dehydroepiandrosterone during natural menopause are associated with loss of muscle mass. Therefore, we sought to evaluate the association between bilateral oophorectomy, sarcopenia, and SO among cancer-free women in the general population. We hypothesized that an abrupt decline in estrogen due to surgical menopause would be associated with sarcopenia and SO.

Methods: The study population included cancer-free women aged 35-70 years who underwent whole body dual-energy x-ray absorptiometry (DXA) scans as part of the U.S. National Health and Nutrition Examination Survey 1999-2006 (N=3,764). Logistic regression models were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for sarcopenia and SO among women who had previously undergone hysterectomy and bilateral oophorectomy (n=552) compared to women with intact uterus and ovaries (n=3,212). Models accounted for complex survey design and were adjusted for age, race, education, weight at DXA scan, weight at age 25, physical activity, smoking, alcohol use, oral contraceptive use, and parity.

Results: The median age at DXA scan was 48 years (interquartile range, 41-56 years) and the median time since oophorectomy was 12 years (5-21 years). About 72.7% of women were non-Hispanic white, 10.8% were non-Hispanic black, 5.8% were Mexican American, and 10.7% other. Women who underwent oophorectomy had two-fold higher odds of sarcopenia (OR, 1.81 [95% CI, 1.12-2.95]) and SO (1.95 [1.17-3.25]) as compared to women with intact uterus and ovaries. The effect was stronger among women who underwent oophorectomy at age <45 (sarcopenia: 2.38 [1.44-3.95]; SO: 2.32 [1.30-4.13]) as compared to women with intact uterus and ovaries, but no difference was observed among women who underwent oophorectomy at age ≥45 (sarcopenia: 1.08 [0.45, 2.58], SO: 1.40 [0.60, 3.28]; sarcopenia: pinteraction=0.031, SO: pinteraction=0.045). Of note, even women with normal BMI (18.5-24.9 kg/m²) at DXA scan who underwent oophorectomy at age <45 years had significantly higher odds of sarcopenia (2.37 [1.15, 4.87]) and SO (2.89 [1.23, 6.75]) as compared to women with normal BMI and intact uterus and ovaries. Conclusion: Women who undergo oophorectomy at a young age have an elevated risk of sarcopenia and SO even while maintaining normal weight. This novel finding, if confirmed in prospective studies, suggests that monitoring young women undergoing oophorectomy for sarcopenia and SO may improve long-term health outcomes.
Impact of raloxifene adherence in breast cancer risk

Mariana Chavez-MacGregor, Xiudong Lei, Hui Zhao, Therese B Bevers, Abenaa Brewster and Sharon H Giordano. 1The University of Texas MD Anderson Cancer Center, Houston, TX.

BACKGROUND: Raloxifene is a selective estrogen receptor modulator that has demonstrated to reduce breast cancer risk and reduce the incidence of vertebral fractures. Based on these effects, raloxifene is used as a risk reduction agent and to prevent osteoporosis in postmenopausal women. Little is known about the raloxifene adherence rates or the relationship between adherence and breast cancer incidence.

METHODS: Women 60 years or older without a breast cancer history were identified in the MarketScan database (2008-2015). We identified women who received raloxifene by searching for prescription claims. Proportion of days covered (PDC) were calculated, adherence was defined as a PDC ≥80% in the first year after initial prescription claim. We identified factors associated with adherence. ICD-9 codes were used to identify incident cases of invasive breast cancer and cumulative incidence rates were calculated. A multivariable Cox model with propensity score method (matching variables included year of claim, age, comorbidities and family history of breast cancer) was used to evaluate the association between raloxifene adherence and breast cancer risk. All statistical tests were two-sided.

RESULTS: A total of 16,179 women were included in the analysis. We identified that during the first year of treatment 6,716 (40.2%) women had a PDC ≥80% and thus were considered to be adherent. Factors associated with increased adherence included the use of generic drug, mail order of 90 days supply and family history of breast cancer (all p<0.001). Using propensity score matching, the 5 year-cumulative incidence of invasive breast cancer was 1.5% among those not adherent and 0.9% among those adherent to raloxifene (p=0.01). Similarly, the 9 year-cumulative rates were 3.6% and 1.9% respectively (p=0.01). After adjusting for potential confounders, patients that were adherent to raloxifene during the first year of treatment had a lower risk of invasive breast cancer compared to those that were non-adherent (HR=0.64; 95%CI 0.04-0.9).

CONCLUSIONS: Among women 60 years of age or older receiving raloxifene, adherence to therapy was associated with lower risk of invasive breast cancer. Efforts to ensure adherence and compliance are crucial so patients can receive full benefit from this therapy.
Tobacco exposure and breast cancer

Nickolas Dreher¹, Tracy M Layton², Barbara A Parker², William P Shibley¹, Irene Acerbi¹, Anne M Wallace², Sarah Blair², John P Pierce², Stanton Glantz¹, Joseph Guydish¹, Robert Hiatt¹, Laura van 't Veer¹, Laura Esserman¹ and Athena Breast Health Network Investigators and Advocate Partners¹. ¹University of California, San Francisco, San Francisco, CA and ²University of California, San Diego, San Diego, CA.

Background: Smoking is a known risk factor for various types of cancer, and breast cancer patients who smoke are known to have higher breast cancer mortality. However, few studies have found an association between smoking and breast cancer incidence or tumor biology. The Athena Breast Health Network distributes an intake questionnaire at the UCSF and UCSD breast care centers which can be used to investigate links between tobacco exposure and the characteristics of incident breast cancer.

Methods: Intake questionnaires were distributed to all new patients at the UCSF and UCSD breast care centers from December 2012 to May 2018. Patients who completed the questionnaire with a known diagnosis of breast cancer were compared to those without in a case-control study. Breast cancer diagnoses were determined by ICD9 diagnosis codes from the patients' medical records. The association of smoking and breast cancer prevalence and biology was analyzed using generalized linear models and Fisher tests in R.

Results: Of the 7727 patients who completed the Athena intake questionnaire at UCSF and UCSD, 5499 consented to have their data used for research. A first analysis was conducted on 4175 UCSF patients alone: 2186 of the UCSF patients who had completed the questionnaire had a documented breast cancer diagnosis, vs 1989 with no known diagnosis at the time of this analysis. 1096 of the 4175 UCSF patients reported having ever smoked, including 73 who had accrued 30 or more pack years. Complete pathology data was available for 1120 cancer patients. Controlling for age, more patients with invasive breast cancer reported having ever smoked, with an odd's ratio (OR) of 2.32 (p = .0043). By including DCIS, the OR drops slightly to 2.26 (p = .0058). Taking alcohol consumption into account as a confounder lowered the OR to 2.19 (p = .0454). Overall, the risk of breast cancer increases with each additional pack year (OR = 1.08, p = .0211), independent of age. There are no significant differences in tumor biology for any smoking group.

Conclusions: A history of smoking is associated with an increased risk of developing breast cancer and is directly related to cumulative pack years exposure. This association should be further validated in cohort studies.
Assessment of clinical trial participation on breast cancer survival

Carol Parise and Vincent Caggiano. Sutter Institute for Medical Research, Sacramento, CA.

Background
Accredited cancer treatment centers offer clinical trials for patients since it is universally accepted that participation in these trials is advantageous.

Purpose
The purpose of this study was to assess whether clinical trial participation was associated with a survival advantage.

Methods
We identified 308,291 cases of first primary female invasive breast cancer from the California Cancer Registry 2000-2015. Participation in a clinical trial was documented. Clinical trials were defined as National Cancer Institute (NCI) sponsored studies such as National Surgical Adjuvant Breast and Bowel Project (NSABP) and Southwest Oncology Group (SWOG); pharmaceutical trials; and local investigator initiated studies.

The distribution of age, race/ethnicity, socioeconomic status (SES), and stage between clinical trial participants and non-participants was compared using contingency tables and the $\chi^2$ Test.

Kaplan-Meier Survival Analysis and the Log Rank test were used to compare differences in breast cancer specific survival between participants and non-participants. Cox Regression Analysis was used to estimate the risk of mortality between participants and non-participants after adjusting for age, race/ethnicity, SES, grade, and treatment. Analyses were conducted separately for each stage. Hazard ratios (HR) and 95% confidence intervals (CIs) were reported.

Results
There were 3,517 (1.1%) patients who participated in a clinical trial. Almost 50% of participants were enrolled in an NCI trial, 38% in a local/investigator initiated study, and 13% were in a trial sponsored by a pharmaceutical company. Trial participation was highest for patients less than 45 years of age (21.9%) and lowest in patients 70 years of age and older (12.3%). Most participants were in stage 2 (44.6%). Participation increased with increasing SES. Only 8.5% of participants were in the lowest SES whereas 35.4% were in the highest SES.

Unadjusted survival analysis indicated that there was no survival advantage for stage 1 patients ($\chi^2 = 0.41, p=0.52$) whereas study participants in stages 2, 3, and 4 had statistically significantly better survival. Adjusted hazard ratios indicated that stage 2 patients participating in a trial had a 23% reduced risk of mortality (HR=0.77; CI: 0.65 - 0.94). For patients in stage 4, the risk of mortality was reduced by 36% (HR=0.64; CI: 0.47 - 0.87). There was no risk reduction for patients in stages 1 and 3.

Conclusion
Only a small percent of patients enroll in breast cancer clinical trials and participation is correlated with age and SES. There is a survival advantage for participation in a clinical trial for stages 2 and 4 patients.
High risk for cardiovascular disease in postmenopausal breast cancer survivors

Daniel de Araújo Brito Buttros¹, Mauro Terra Branco¹, Claudio Lera Orsatti¹, Jorge Nahas-Neto¹ and Eliana Aguiar Petri Nahas¹.
¹Botucatu Medical School/UNESP, Botucatu, São Paulo, Brazil.

Background: The majority of women diagnosed with breast cancer are considered to have a good prognosis and can expect to survive the disease. Cardiovascular risk in postmenopausal women treated for breast cancer is higher than in women without cancer.

Objective: To evaluate cardiovascular risk factors in postmenopausal breast cancer survivors, in comparison to postmenopausal women without breast cancer.

Methods: In this cross-sectional study, 96 postmenopausal breast cancer survivors were compared to 192 postmenopausal women (controls), aged 45 to 75 years. The main group included women with amenorrhea > 12 months, aged ≥45 years, with a histological diagnosis of breast cancer, without metastatic disease and without established cardiovascular disease (CVD). The control group consisted of women with amenorrhea > 12 months, aged ≥45 years, without breast cancer and CVD. Groups were matched by age, time since menopause, and body mass index (BMI) in a ration of 1 case to 2 controls, according to sample calculation, with a minimum of 92 breast cancer survivors. Clinical and anthropometric data (BMI and waist circumference) were collected by interview and physical examination. For biochemical analysis, total cholesterol, HLD, LDL, triglycerides, glucose and insulin levels were measured. Women presenting with three or more of the following criteria were diagnosed with metabolic syndrome (MetS): waist circumference (WC) ≥ 88 cm; TG ≥ 150 mg/dL; HDL cholesterol <50 mg/dL; blood pressure ≥ 130/85 mmHg; glucose ≥ 100 mg/dL. For measurement of plasma HSP 60 and 70 concentrations, immunoassays were used (ELISA test). Atherosclerotic disease was determined by intima-media thickness (IMT> 1 mm) of the carotid arteries and / or by the presence of atheromatous plaque, assessed by carotid artery ultrasound (scanner duplex). For statistical analysis, Student's t-test, Gamma Distribution (asymmetric variables), Chi-Square Test and Logistic Regression (odds ratio-OR) were used.

Results: Breast cancer survivors had high mean systolic and diastolic blood pressure (p <0.001), and mean blood triglycerides and glucose, above desirable levels (p <0.05). Breast cancer patients had higher HSP60 levels and lower HSP70 levels than controls (p <0.05). Atheromatous plaque occurred more frequently in breast cancer survivors than in controls (19.8% vs. 9.4% respectively) (p <0.05). Analysis of risk adjusted for age, time since menopause and BMI, showed that women treated for breast cancer have a significantly higher risk of MetS (OR = 4.21, 95% CI 2.28-7.76), atheromatous plaque (OR = 2.61, 95% CI 1.19-5.72), diabetes (OR=4.42; 95%CI 1.86- 10.49), hypertriglyceridemia (OR = 2.32, 95% CI 1.33-4.0) and increased waist circumference (OR = 11.22, 95% CI 4.0 - 31.65) than women without breast cancer.

Conclusion: Postmenopausal breast cancer survivors are at higher risk for metabolic syndrome, diabetes, atherosclerotic disease, hypertriglyceridemia and abdominal obesity (major risk factors for cardiovascular disease), in comparison to postmenopausal women without breast cancer.
Factors impacting the accuracy of self-reported breast procedures among women with and without breast cancer

Marcy L Schaeffer¹, Betty May¹, Ashley Cimino-Mathews², Mikhaila Orellana¹, Michelle McCullough¹, Brenna Hogan¹, Deborah Armstrong²,³ and Kala Visvanathan¹,²,³. Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; Johns Hopkins School of Medicine, Baltimore, MD and Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD.

Background: Clinical/epidemiologic observational studies frequently rely on participants' recall for information about breast procedures. However, there is limited data on the accuracy of self-reported breast procedures. To address this knowledge gap and inform future study design and collection and interpretation of similar data, we investigated the impact of type, diagnosis, age, time, and other patient characteristics on the accuracy of self-report in a prospective cohort.

Methods: All benign breast biopsies, lumpectomies, and mastectomies for breast cancer treatment among women enrolled in the BOSS Cohort, a prospective study of women and men with a familial risk of breast/ovarian cancer, were identified. Study staff obtained pathology reports for 93% of women from self-reported breast procedure locations. For this analysis, we focused on 577 women who had at least one ascertained pathology report, and who self-reported at least one breast procedure at baseline. We estimated the percentage of self-reports (95% confidence interval (CI)) with matching pathology report within 6 months (+/- 6 months), and agreement between self-reported procedures and pathology-confirmed diagnoses (normal/benign vs. atypical hyperplasia vs. LCIS, and DCIS vs. invasive cancer) with the Kappa statistic. We also examined predictors of an accurate biopsy self-report, including age at baseline, personal and family history of breast cancer, educational attainment, and time between biopsy and baseline, using logistic regression models.

Results: At baseline, 158 women reported having at least one benign biopsy, 193 women reported having a lumpectomy for cancer treatment, and 174 women reported having a mastectomy for cancer treatment. The median time between biopsy, lumpectomy, mastectomy, and baseline was 9 years, 2 years, and 2 years, respectively. Fifty-seven percent (95% CI: 49-64.5%) of benign biopsy self-reports, 90.7% (95% CI: 85.6-94.1%) of lumpectomy self-reports, and 85.1% (95% CI: 78.9-89.7%) of mastectomy self-reports had a matching pathology report within 6 months. Further diagnostic agreement was moderate for biopsies, lumpectomies, and mastectomies with Kappa statistics of 0.65, 0.66, 0.65, respectively. Age at baseline (p-interaction =0.01) and time (p-interaction = 0.03) were independent and joint predictors of accurate biopsy self-reports. Women less than 49 years old had the largest reduction in odds of having an accurate self-report (26%) for every additional year between biopsy and baseline [adjusted odds ratio = 0.74 (95% CI: 0.63-0.88)]. Similarly, women with a biopsy within 4 years prior to baseline had a 10% reduction in the odds of having an accurate self-report with increasing age [adjusted odds ratio = 0.9 (95% CI: 0.84-0.97)].

Conclusions: In this highly-educated cohort, the overall accuracy of self-report of benign biopsies was only modest, and the accuracy of self-report of lumpectomies and mastectomies was lower than expected. This study suggests that age at baseline and time between procedure and baseline are important predictors of accuracy of self-report and should be considered when utilizing self-reported information. Furthermore, where possible, prospective collection of breast procedure data should be prioritized.
Breastfeeding experience among breast cancer patients in the modern era

Jessica C Gooch¹, Jennifer Chun¹, Talia Jubas², Amber Guth¹ and Freya Schnabel¹. ¹New York University Medical Center, New York, NY and ²New York University, New York, NY.

Introduction: In recent years, the uptake of breastfeeding has become more common as it is regarded as healthy and beneficial for both mother and infant. The process of parturition and lactation plays a role in the normal differentiation and development of breast tissue, and multiparity has been associated with a decreased risk for breast cancer. The current study sought to describe the breastfeeding experience of a modern cohort of women with newly diagnosed BC, and to examine the clinicopathologic characteristics of their disease.

Methods: A retrospective review of our institutional Breast Cancer Database from 2009-2017 was performed to identify women with at least one full term pregnancy (FTP). Clinicopathologic and demographic information was recorded, including breastfeeding experience and cumulative duration of nursing. Women were grouped by self-reported breastfeeding experience and duration of breastfeeding for analysis. Pearson's chi-square tests were performed.

Results: Of 1919 patients, 1053 (54.9%) reporting breastfeeding. Breastfeeding increased from a low of 30.4% among women with first FTP (FFTP) in the 1950's to 84.6% with FFTP in the 2010's. There were no significant differences between those who did and did not breast feed with regards to race, family history, BRCA status, pathologic stage, grade, tumor histology, lymphovascular invasion (LVI), multifocality, tumor size or receptor status. When stratified by duration of breastfeeding, the most striking finding was that women who breastfed for >12 months were more likely to have tumors associated with LVI (p = 0.028).

**Conclusions:** Breastfeeding experience was not generally associated with significant differences in tumor or patient characteristics. However, breastfeeding for longer than 12 months was associated with LVI. It is possible that changes in the breast tissue that occur during the process of pregnancy and prolonged lactation may influence future tumor development. These findings are hypothesis generating and suggest that the relationship of prolonged breastfeeding and breast cancer development should be investigated further.
Family history of breast cancer and mammographic density in premenopausal women

Yunan Han\textsuperscript{1,2}, Xiaoyu Zong\textsuperscript{1}, Graham A Colditz\textsuperscript{1,3} and Adetunji T Toriola\textsuperscript{1,3}. \textsuperscript{1}Washington University School of Medicine, St. Louis, MO; \textsuperscript{2}First Hospital of China Medical University, Shenyang, Liaoning Province, China and \textsuperscript{3}Alvin J. Siteman Cancer Center at Barnes-Jewish Hospital and Washington University School of Medicine, St. Louis, MO.

Introduction: Mammographic density and family history of breast cancer (FHBC) are independent risk factors for breast cancer. Women with dense breasts have a 4-6-fold increased risk of breast cancer and women with FHBC have a 1.5-3-fold increased risk of breast cancer. However, there is little data on the associations of FHBC with mammographic density, especially in premenopausal women. To address this, we investigated the associations of FHBC in first-degree relatives with mammographic density in premenopausal women.

Methods: We used data from 375 cancer-free premenopausal women who were during routine screening mammography at Washington University in St. Louis in 2016. We used Volpara to measure volumetric measures of density including volumetric percent density, dense volume, and non-dense volume. We collected data on first-degree relatives (mother, sister) and numbers of first degree relatives (0, 1, ≥2) with a positive FHBC. We used multivariable linear regression model, adjusted for age, BMI, parity, race, age at menarche, and alcohol consumption, to determine the associations of FHBC and log-transformed volumetric percent density, dense volume, and non-dense volume. Beta coefficients (β) were evaluated and back transformed for easier interpretation.

Results: The mean age of participants was 47.5 years (range=32-58). The mean BMI was 30.8 kg/m\textsuperscript{2} (range =17.9-63.1). Volumetric percent density was 25% (p-value<0.001) higher in women who had a FHBC compared with women who had no FHBC.

*Adjusted for age, BMI, parity, race, age at menarche, and alcohol consumption.

Table 1. Associations of family history of breast cancer (FHBC) and volumetric percent density (VPD), and dense volume (DV) in 375 premenopausal women.

Conclusions: Premenopausal women with a first-degree FHBC have higher volumetric percent density. Our findings could help identify high-risk women who may benefit from targeted screening.
The impact of Charlson comorbidity index on survival of triple negative breast cancer

Carol Parise and Vincent Caggiano. 1Sutter Institute for Medical Research, Sacramento, CA.

Background
Patients with cancer and comorbidities have been found to have poorer survival since they may be unable to receive or complete treatments. It is not clear if comorbid conditions impact survival of patients in all stages of disease and all ER/PR/HER2 subtypes.

Purpose
The purpose of this study was to determine how the Charlson Comorbidity Index (CCI) affected the risk of mortality of triple negative breast cancer (TNBC) within each stage of disease.

Methods
We accessed 22,503 cases of TNBC and documented CCI from the California Cancer Registry 2000-2015. The CCI is a weighted index based on the presence of certain comorbid conditions twelve months prior through six months following the cancer diagnosis and weighted by the severity of those conditions. A score of 0 is interpreted as no significant comorbidity burden and scores of 3 or more are generally interpreted as a high comorbidity burden. Kaplan-Meier Survival Analysis and the Log Rank test were used to compare differences in breast cancer specific survival between patients with a CCI of 1, 2 or higher (2+) versus a CCI of 0. Cox Regression Analysis was used to estimate risk of mortality of CCI after adjusting for age, race/ethnicity, socioeconomic status, grade, and treatment. Analyses were conducted separately for each stage. Hazard ratios and 95% confidence intervals (CIs) were reported.

Results
There 16,664 (74.1%) cases with a CCI of 0; 3,915 (17.4%) with a CCI of 1; 1,055 (4.7%) had a CCI of 2, and the remaining 869 (3.9%) cases of TNBC had a CCI of 3 or higher. Unadjusted survival analysis indicated that for stages 2 and 3, there was increased survival with decreasing CCI score. For stages 1 and 4, survival was only better for patients with a CCI of 0 versus a CCI of 2+.

Cox regression analysis indicated that the CCI made no difference in risk of mortality for patients with stage 1 disease. Patients with a CCI of 2+ had an increased risk of mortality when compared with a CCI of 0 for stage 2 (HR = 1.48, CI: 1.25-1.77), stage 3 (HR=1.25, CI: 1.03-1.52) and stage 4 (HR = 1.53; CI: 1.22-1.92).

Conclusion
Comorbidity as measured by the CCI does not increase the risk of mortality for patients with stage 1 TNBC and only increases risk of mortality in higher stages for patients with a CCI score of 2 or higher.
Assessment of short inter-pregnancy interval in breast cancer diagnosed during pregnancy

Hector Diaz-Perez1,2, Raul Del Toro-Mijares3, Edna A Lopez-Martinez1,2, Jose F Muñoz-Lozano1,2, Alan Fonseca1,3, Alejandra Platas1,3, Bertha A Martinez-Cannon1,2, Regina Barragan-Carrillo1,2, Janeth Castro-Carrasco1,2, Stephany Limon-Gomez4 and Cynthia Villarreal-Garza1,2,3. 1Joven & Fuerte: Programa para la Atencion e Investigacion de Mujeres Jovenes con Cancer de Mama, Mexico City, Mexico; 2Tecnologico de Monterrey, Centro de Cancer de Mama, Monterrey, Mexico; 3Instituto Nacional de Cancerologia, Departamento de Tumores Mamarios y Departamento de Investigacion, Mexico City, Mexico and 4Centro Medico Nacional de Occidente, Departamento de Oncologia Medica, Guadalajara, Mexico.

**Background:** The relationship between pregnancy and breast cancer (BC) risk is not fully understood. Most of the literature has described this interaction in terms of the age at first pregnancy and the number of full-term pregnancies. During the prospective accrual of the “Joven & Fuerte” young women with BC program in Mexico, we identified patients with pregnancy-associated BC (PABC) that experienced a short inter-pregnancy interval (SIPI) (<18 months between a live birth and the beginning of a following pregnancy). To our knowledge, there are no descriptions of the interaction between SIPI and PABC.

**Objective:** We aim to assess the occurrence of SIPI in patients with PABC, as well as describe their clinical features at presentation.

**Results:** We included patients accrued in the “Joven & Fuerte” program from August 2014 and June 2018 at three Mexican cancer centers. A total of 375 patients ≤40 years-old with newly-diagnosed BC were assessed. 37 patients were diagnosed with PABC (10%), 21 during pregnancy and 16 after pregnancy. 6/37 (16%) patients with PABC experienced a SIPI, all diagnosed during pregnancy (28% of 21). The main clinicopathological features are described in the table 1.

**Conclusion:** According to the phenomena seen in this cohort of young BC patients, we hypothesize that SIPI may increase the incidence and/or modify the clinical outcomes of PABC. The evidence from clinical and laboratory data suggest that the mechanisms that could alter the interaction include, but are not limited to, the prolongation of the exposure to high concentrations of estrogens or their genotoxic metabolites, interaction with the effect of progesterone and other pregnancy-associated hormones on breast tissue, and immunologic factors. To date, to our knowledge there is no evidence about the effect of SIPI in PABC. Thus, research in this area should be encouraged, particularly in vulnerable women in limited-resource settings, where SIPI is, unfortunately, a common occurrence, and might represent a risk factor for BC/PABC.
Introduction: Pregnancy-associated breast cancer (PABC) refers to breast cancer (BC) diagnosed during pregnancy, lactation, or in the postpartum period. There is evidence that PABC is associated with a poorer prognosis, and that the development of the disease is influenced by the unique hormonal milieu of pregnancy. The purpose of this study was to investigate the clinicopathologic characteristics associated with PABC in a contemporary cohort of women with newly diagnosed BC.

Methods: Our institutional Breast Cancer Database was queried for women diagnosed with breast cancer between 2010-17 who had at least one full term pregnancy (FTP). Variables of interest included patient demographics and clinical and tumor characteristics. PABC was defined as breast cancer diagnosed within 24 months of delivery. Statistical analyses included Pearson’s chi-square and logistic regression.

Results: Out of a total of 1934 women, 42 (2.2%) had PABC. Median follow up in the total cohort was 4.5 years. After adjusting for age at diagnosis, PABC was associated with older age at first FTP, ethnic minority status, BRCA mutation carriers, presentation with a palpable mass, higher histologic grade, and ER-negative and triple negative receptor status. Variables that were not significantly different between PABC and non-PABC cases included tumor histology, multifocality, presence of lymphovascular invasion, and family history of breast cancer.

*P-values are age-adjusted.

**Conclusions:** The association of PABC with ethnic minority status in our cohort is interesting and may be reflected in the increased proportion of triple negative breast cancers in the PABC group. In our contemporary cohort, PABC was associated with older age at first FTP. As more women delay childbearing, risk for PABC may increase. Our findings suggest that women who become pregnant at older ages should be followed carefully during pregnancy and in the postpartum period, especially if they are BRCA mutation carriers. The optimal approach for monitoring older women during pregnancy and the postpartum period is unclear. Clinical breast exam may play an important role, especially for those women known to be at increased risk for breast cancer.
Gestational breast cancer in Singapore women

Qing Ting Tan¹, Fuh Yong Wong²,³, Veronica S Alcantara¹, Rehena Ganguly⁴ and Kiley Wei-Jen Loh²,³. ¹KK Women’s and Children’s Hospital, Singapore, Singapore; ²National Cancer Centre Singapore, Singapore, Singapore; ³Singapore General Hospital, Singapore, Singapore and ⁴Duke-NUS Medical School, Singapore, Singapore.

Background
Gestational breast cancer (GBC), diagnosed during pregnancy or in the first postpartum year, is expected to rise in incidence due to increasing maternal age. GBC poses unique challenges in diagnosis and treatment as clinicians seek to provide optimal treatment for these young patients without compromising neonatal outcomes. We present our retrospective findings from the first study on gestational breast cancer in Singapore.

Methods
We performed a retrospective study on 88 patients with gestational breast cancer diagnosed from April 2003 to April 2017 at three centres in Singapore. Demographic details, tumour histopathological characteristics, stage, treatment and outcomes data was collected and analysed.

Results
Eighty-eight patients were diagnosed with GBC at a median age of 35.9 years (26-43 years). Fifty (56.8%) were diagnosed intrapartum and 38 (43.2%) were diagnosed postpartum. Seventeen (19.8%) had a family history of breast cancer but none had proven BRCA mutation. Seventeen patients (19.3%) presented with stage 1, 36 (40.9%) with stage 2, 25 (28.4%) with stage 3, 5 (5.7%) with stage 4 disease. Seventeen patients underwent termination of pregnancy (27.9% of patients diagnosed during pregnancy). Seventeen (19.3%) of patients received neoadjuvant chemotherapy, 8 of whom received it during pregnancy. Forty-eight (54.5%) received adjuvant chemotherapy, 4 of whom received it during pregnancy. Two patients received palliative chemotherapy during pregnancy. Aside from one case of hearing impairment, there was no other documented neonatal complication for patients who received intrapartum chemotherapy.

The 5-year and 10-year overall survival (OS) was 80% and 66%. According to the Singapore National Cancer Registry, the 5-year OS for women younger than 44 years of age was 88.9%, therefore suggesting a lower OS in patients with GBC. The 5-year and 10 year disease-free survival (DFS) of our patients was 73% and 60% respectively. Diagnosis of cancer postpartum conferred a higher risk (hazard ratio (95%CI) 1.86 (0.55, 6.28) of mortality compared to those diagnosed intrapartum. Univariate Cox proportional hazard regression model showed that nodal positivity and clinical stage were significantly associated with DFS while only clinical stage was significantly associated with OS. Race was found to affect survival with Malay patients having a lower DFS compared to Chinese patients.

Conclusion
GBC patients in Singapore have a lower survival rate. Diagnosis of cancer postpartum confers a higher risk of mortality. This might be due to a delay in diagnosis and treatment. Malay patients have a lower survival compared to Chinese patients. Studies into genetic and social factors might shed light on how ethnicity affects survival of these patients.
Screening and risk reducing surgeries for patients at high risk for breast and ovarian cancer at an integrated care setting

Monica Ter-Minassian1, Kala Visvanathan2, Celeena R Jefferson1, Marcy L Schaeffer2 and Pim Suwannarat1. 1Kaiser Permanente Mid-Atlantic States, Rockville, MD and 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

**Background:** Current US guidelines recommend more intensive screening and preventive strategies for patients with a known pathogenic germline mutation or a high lifetime risk based on breast cancer risk prediction models. The American Cancer Society, for example, recommends that yearly mammogram alternating with MRI screening should be considered as early as 30 years old in women with a lifetime breast cancer risk of > 20%. Furthermore, NCCN recommends that BRCA1/2 mutation carriers consider additional risk-reducing strategies, including bilateral mastectomy, bilateral oophorectomy at age 35, or post-child bearing, and hormonal chemoprevention. It is unclear what the uptake of screening and risk reducing strategies are after an HRBROC assessment and recommendations by Genetics at an integrated care setting.

**Methods:** We retrospectively studied female patients diagnosed as high risk for breast and ovarian cancer (HRBROC) (regardless of prior cancer) and/or tested for BRCA mutations by a genetic counselor or physician geneticist at Kaiser Permanente Mid-Atlantic States (KPMAS) Genetics clinics between 2005-2016. We identified cancer diagnoses, mammogram and MRI screening, mastectomies and oophorectomies with ICD diagnosis or CPT procedure codes during the study period. We defined prophylactic mastectomy or prophylactic oophorectomy as occurring either 180 days prior to, or without a diagnosis of breast or ovarian cancer respectively. We assessed screening with a mammogram or MRI, post Genetics visit for patients 30-75yrs old at time of HRBROC dx, and had no breast cancer prior to, or within 180 days, of the Genetics visit.

**Results:** Our cohort included 813 women with a HRBROC diagnosis, with a median 51 yrs of age at diagnosis, 45% White, 38% Black and 15% other race. Since genetics services for cancer at KPMAS were established recently, 98% of visits occurred after 1-1-2013. Table 1 shows the distribution of cancer diagnoses and surgeries pre and post Genetics visit. 249 Breast cancer-free patients were screened post Genetic visit between mid-2013-2016: 159 (64%) had at least 1 screening test, 68 had two to three and only 3 women had four to six screening tests. The median time to the latest screen after HRBROC dx was 14.4 mo, (range 2 days to 39 mo). Post-Genetics screening frequency did not differ by race.

**Conclusion:** The majority of women visited Genetics after a diagnosis of breast or ovarian cancer. Patients received prophylactic oophorectomies more often than prophylactic mastectomies. Screening in cancer free patients with a HRBROC diagnosis appears to be limited to 1-3 screens post diagnostic visit. Our findings suggest that earlier detection of patients at high risk for breast and ovarian cancer and closer monitoring is needed.

| Table 1. Cancer diagnoses and Surgeries Pre and Post Genetics Visit for HRBROC (2004-2016) (N=813) |
|---------------------------------|-----------------|-----------------|-------|
|                                | pre-Genetics    | post-Genetics   | Total |
| Breast Cancer diagnosed        | 513             | 14              | 527   |
| Post cancer Mastectomy         | 319             | 8               | 327   |

Impact of route of administration of estradiol (oral vs. transdermal) on genotoxic estrogens concentrations in girls with ovarian failure due to Turner syndrome: Potential implications for breast cancer prevention

Gerardo Colon-Otero 1, Lournaris Torres-Santiago 5, Richard Santen 2, Veronica Mericq 3, Judith Ross 4, Ligeia Damaso 5, Jobayer Hossain 5, Qingqing Wang 6, Clementina Mesaros 6, Ian A Blair 6 and Nelly Mauras 5. 1 Mayo Clinic, Jacksonville, FL; 2 University of Virginia, Charlottesville, VA; 3 University of Chile, Santiago, Chile; 4 Nemours Children’s Health System, Wilmington, DE; 5 Nemours Children’s Health System, Jacksonville, FL and 6 University of Pennsylvania, Philadelphia, PA.

Objective: The established link between estrogen and breast cancer occurs via both estrogen receptor (ER)-mediated and non ER-mediated mechanisms. The term genotoxic estrogens describes mutagenic metabolites, including estrogen catechols and quinones, which have been linked to breast carcinogenesis in post-menopausal women. Recent data showed that childhood obesity is associated with significantly higher levels of genotoxic estrogens in the blood compared with lean children, raising the possibility of a potential pathogenic roles of these metabolites in breast cancer starting even prior to the onset of puberty (Mauras et al: J Clin Endocrinol Metab. 100:2322, 2015). A finding of higher levels of genotoxic estrogens associated with oral estradiol may have breast cancer prevention implications. We hence aimed to assess if the route of administration of 17β estradiol (E₂) affects the accumulation of genotoxic estrogen metabolites in a model of ovarian failure in young girls with Turner Syndrome.

Methods: Stored plasma were used from 40 adolescents with Turner’s who participated in a previous 12 months randomized controlled trial of the metabolic impact of E₂ orally (2mg/d) vs. transdermally (100μg/d). The doses of oral and transdermal E₂ were determined to result in similar plasma levels of unconjugated E₂. Previously we had reported that despite the similar plasma levels of unconjugated E₂, the oral E₂ administration route was associated with higher levels of biologically active estrogen activity than the transdermal route (Torres-Santiago L et al: J Clin Endocrinol Metab. 98:2716, 2013). In this study, we measured 12 estrogen metabolites (conjugated and unconjugated) using a highly sensitive LCMSMS assay. Results from 48 normally menstruating adolescents were used for comparison.

Results: After treatment, least square mean (SE) total (conjugated plus unconjugated) E₂ and estrone (E₁) concentrations were higher in the oral vs. transdermal group (p<0.0001), as were catechol-estrogens 4-OH-E₂ (149 vs. 28 (49) pmol/L), 2-OH-E₂ (300 vs 76 (52)), 4-OH-E₁ (450 vs 105 (113)), 2-OH-E₁ (304 vs 740 (684)) and 16α-OH-E₁ (3007 vs 157 (534)) (<0.001 between groups). Levels were much closer to controls in the transdermal group.

Conclusions: Common feminizing doses of oral estradiol for 12 months result in greater accumulation of unphysiologic, genotoxic estrogens than transdermal estradiol, expanding concerns about oral estrogens’ first hepatic passage contributing to the accumulation of these metabolites. These metabolites have the potential for inducing breast cancer in post-menopausal women. These results suggest the potential benefit of preferential use of transdermal versus oral estrogens as replacement and possibly contraceptive options, in the prevention of breast cancer. Further studies to assess long-term risks of these metabolites in women taking different forms of estrogen replacement are needed.
Obesity influences the character of the breast cancer in postmenopausal women in Japan

Masahiko Suzuki¹ and Hiroyuki Takei². ¹Kitamurayama Hospital, Higashine, Yamagata, Japan and ²Nippon Medical School, Tokyo, Japan.

Background: We know Estrogen Receptor (ER) positive and/or Progesterone Receptor (PgR) positive tumors tend to develop more frequently in obese individuals in postmenopausal women. However, the average body size of a Japanese woman is relatively smaller than that of a Caucasian woman. There are few reports about the influence of the obesity to the character of the Japanese breast cancer women and the tendency is not clear. The aim of this study is to clarify whether the tendency is the same even in Japanese breast cancer women. Furthermore, we investigate whether HER2 expression (HER2) and Ki-67 index (Ki-67) have some relations with the height (HT), the weight (WT) and the body mass index (BMI) in Japanese breast cancer women.

Methods: HT and WT of 279 Japanese women with breast cancer in Kitamurayama hospital were evaluated. The mean HT and WT of them are 153.6cm and 54.9kg. Subsequently, the women’s BMI (WT/(HT)^2) was calculated. The mean BMI was 23.3. The ER and PgR were stained for immunohistochemical (IHC) analysis. Regardless of the intensity, stained cases were defined as positive. HER2 was divided into HER2 negative (IHC score 0, +1 and/or FISH negative) or positive (IHC score +3 and/or FISH positive). Ki-67 was determined by staining with MIB-1 antibody, and the cutoff value was decided on 20%, and divided into two groups of more than 20% (Higher) and less than 20% (Lower). Then, we examined the relationship of HT, WT and BMI with ER, PgR, HER2 and Ki-67 in postmenopausal and premenopausal women.

Result: In postmenopausal women, WT and BMI were significantly higher in ER positive (p=0.0230, p=0.0129). WT and BMI were also significantly higher in PgR positive (p=0.0049, p=0.0294,). There was no significant difference between HER2 positive and Her2 negative, and between Ki-67 Higher and Ki-67 Lower either. In premenopausal women, no significant association was observed in all items.

Conclusion: In postmenopausal women, HT did not have the significant difference between ER (and PgR) positive and ER (and PgR) negative. However, ER (and PgR) positive were significantly higher in WT and BMI. It was thought that the obesity influences the character of the breast cancer in postmenopausal women. Compared to less obese postmenopausal Japanese women with breast cancer, more obese postmenopausal Japanese women have a propensity for developing hormone sensitive tumors.
Neoadjuvant chemotherapy infusion in the arm ipsilateral to breast cancer increases the risk of lymphedema

Anke Bergmann¹, Marcelo A Bello¹, Luiz CS Thuker¹, Mauro F Andrade² and José Luis Bevilacqua³. ¹Brazilian National Cancer Institute, Rio de Janeiro, RJ, Brazil; ²Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil and ³Hospital Sírio Libanês, São Paulo, Brazil.

**Background:** Neoadjuvant chemotherapy (NAC) has been administered to clinically axillary positive breast cancer (BC) patients. Current guidelines still recommend axillary lymphadenectomy (AL) in patients with persistent positive axillary lymph node disease. We aimed to evaluate the association of NAC and/or adjuvant chemotherapy (CT) infusion in the ipsilateral upper limb (IA) with AL and the occurrence of lymphedema (LE) secondary to BC treatment. **Methods:** A prospective cohort study of 683 women subjected to AL and treated with NAC and/or adjuvant CT for BC. The patients were evaluated before treatment, immediate and every 6 months after surgery. Cumulative incidence and population attributable risks of LE were calculated. **Results:** 8-year cumulative incidence of LE was 33.1%. NAC and CT infusion and infusion of >2 cycles into the IA respectively increased by 1.68, 1.67 and 1.78 times the risk of LE respectively (all \(P<0.01\)). LE could be avoided in 9.4% of cases if the CT infusion had not been administered in the IA. **Conclusions:** 33.1% of women developed LE. The risk of LE was increased among women who received CT in the IA. Avoidance of NAC or adjuvant CT in the IA could prevent 9% of the LE cases observed in this population.

Plasma metabolomic signatures associated with long-term breast cancer risk in the SU.VI.MAX prospective cohort

Lécuyer Lucie¹, Dalle Céline², Lyan Bernard², Demidem Aicha³, Rossary Adrien⁴, Vasson Marie-Paule³,⁴, Petera Mélanie², Lagree Marie⁵, Ferreira Tom³, Centeno Delphine², Zelek Laurent¹,⁶, Galan Pilar¹, Hercberg Serge¹,⁶, Deschasaux Mélanie¹, Partula Valentin¹, Srour Bernard¹, Latino-Martel Paule¹, Kesse-Guyot Emmanuelle¹, Druesne-Pecollo Nathalie¹, Manach Claudine⁷, Durand Stéphanie², Pujos-Guillot Estelle² and Touvier Mathilde¹. ¹CRESS, Inserm U1153, Inra U1125, Cnam, Paris 13 University, Nutritional Epidemiology Research Team (EREN), Bobigny, France; ²Clermont Auvergne University, Inra, UNH, PFEM MetaboHUB Clermont, Clermont-Ferrand, France; ³Clermont Auvergne University, Inra, UMR 1019, UNH, CRNH Auvergne, ECREIN, Clermont-Ferrand, France; ⁴Clermont Auvergne University, Inra, UMR 1019, UNH, CRNH Auvergne, Micro-Card, Clermont-Ferrand, France; ⁵Clermont Auvergne University, Chemical Institute of Clermont-Ferrand, PFEM MetaboHUB Clermont, Aubière, France; ⁶Anticancer Center Jean-Perrin, CHU Clermont-Ferrand, Clermont-Ferrand, France; ⁷Avicenne Hospital, Bobigny, France and ¹Clermont Auvergne University, Inra, UNH, CRNH Auvergne, Micro-Card, Clermont-Ferrand, France.

**Purpose:** Breast cancer is a major cause of death in occidental women. Mechanisms involved in its etiology remain misunderstood. Metabolomics is a powerful tool which may help elucidating novel biological pathways and identify new biomarkers in order to predict breast cancer well before symptoms appear. The aim of this study was to investigate whether untargeted metabolomic signatures from blood draws of healthy women could contribute to better understand and predict the long-term risk of developing breast cancer.

**Methods:** A nested case-control study was conducted within the SU.VI.MAX prospective cohort (13 years of follow-up) to analyze baseline plasma samples of 211 incident breast cancer cases and 211 matched controls by LC-MS mass spectrometry. Multivariable conditional logistic regression models were computed.

**Results:** 83 ions were significantly associated (corrected-pvalue <0.05) with breast cancer risk. Notably, we observed that a lower plasma level of O-succinyl-homoserine and higher plasma levels of valine/norvaline, glutamine/isoglutamine, 5-aminovaleric acid, phenylalanine, tryptophane, α-glutamyl-threonine, ATBC, 2-amino-cyanobutanoic acid and pregnene-triol sulfate were associated with an increased risk of developing breast cancer during follow-up. Corrected-pvalues ranged from 0.009 (OR=1.43[1.14-1.78] for phenylalanine and OR=1.45[1.15-1.83] for valine/norvaline) to 0.03 (OR=1.28[1.03-1.58] for 2-amino-cyano-butoanoic acid).

**Conclusion:** Several pre-diagnostic plasmatic metabolites are strongly associated with long-term breast cancer risk. If confirmed in other independent cohort studies, these results could help to identify healthy women at higher risk of developing breast cancer in the subsequent decade and to propose a better understanding of the complex mechanisms involved in its etiology.

**Trial registration:** SU.VI.MAX, clinicaltrials.gov NCT00272428. Registered 3 January 2006

Patterns of failure in a predominantly black, inner city cohort of triple negative breast cancer patients at a single institution

Stephanie R Rice¹, Hua-Ren Cherng¹, Muhammad Hamza¹, Shruti Murali¹, Paula Rosenblatt¹, Emily Bellavance¹, Sally Cheston¹, Neha Amin¹ and Elizabeth M Nichols¹. ¹University of Maryland Medical Center, Baltimore, MD.

Introduction: Triple negative breast cancer (TNBC) accounts for 12-17% of breast cancer (BC) in the US, but behaves much more aggressively. It occurs more commonly in younger, black women and death within two years of diagnosis is more common in this subset of BC compared to hormone receptor positive BC. At the University of Maryland Greenebaum Comprehensive Cancer Center, we see a higher proportion of TNBC and present our comprehensive evaluation of the patterns of failure in women with TNBC treated at our urban breast center.

Materials/Methods: A retrospective review of TNBC patients treated from 2005-2017 identified 198 patients with Stage I (33%), Stage II (47%), Stage III (16%) and Stage IV (4%) TNBC. The patients were all female, median age of 54 years (range 22-86 years), 64% black, 40% married, 7% BRCA mutated, and 3% HIV positive. Tumor characteristics revealed 93% infiltrating ductal carcinoma, 68% grade 3, and 18% with lymphovascular space invasion. Self-palpation of the lesion occurred in 76% of women, and the lesion was in the upper outer quadrant 62% of the time. Thirty percent of pts had neoadjuvant and 67% adjuvant chemotherapy. Ninety-eight percent of pts underwent surgical resection, 55% had lumpectomy and 61% sentinel lymph node biopsy. Adjuvant radiation was given in 56% of patients with a median dose of 60 Gy (range 16-70 Gy). Chi-square testing was used to compare variables, while logistic regression with Kaplan-Meier estimate was used to calculate overall survival (OS) and freedom from recurrence (FFR).

Results: With a median follow up of 45 months, 33 (17%) documented failures occurred. At time of first documented failure, 30% were local (L), 6% regional (R), 22% distant (D), 6% combination of L/R, 12% combination of L/R/D, 9% L/D, and 15% R/D, with a total combined failure pattern in 42% of pts. There was no significant difference in failure patterns between white and black pts (p=0.50, Table 1). The 2 and 5 year OS was 88% and 80%, respectively. Median survival was not reached in our cohort. The 2 and 5-year FFR was 90% and 84%, respectively with a median time to any failure of 16 months after initiation of therapy and median OS of 29 months for these pts.

Conclusion: Our work shows that with modern BC therapies treatment outcomes for pts with TNBC are improved and 84% are free of disease at 5 yrs after the initial diagnosis. The patterns of failure in TNBC are complex, did not vary by race, and showed the largest proportion of our pts (58%) failing in distant and locoregional sites simultaneously, while an additional 30% of pts fail locally only. These failure patterns did not differ significantly based on race. Future efforts will identify pts most at risk for treatment failure for consideration of treatment intensification, as salvage options are limited when treatment failure occurs.

A simple intervention for long-term relief of chronic post mastectomy pain

Holly J Keane¹, Amal L Khoury¹, Ava Hosseini¹, Flora P Varghese¹, Rita Mukhtar¹, Suzanne E Eder¹, Jasmine Wong¹ and Laura J Esserman¹. ¹UCSF Mt Zion Campus, San Francisco, CA.

**Background:** Post-mastectomy pain syndrome (PMPS) is a common and often debilitating condition. One common cause likely results from injury to the T4 and T5 sensory nerves during breast surgery, with resulting neuroma formation. It manifests as a pain syndrome diagnosed by “trigger points” that reproduce exquisite pain upon palpation. Pain specialists have found a combination of corticosteroids and local anaesthetic given through perineural infiltration, at other sites, effective in alleviating these neuromas or trigger points. Utilizing this principle, we initiated a quality improvement project to treat PMPS. This perineural injection led to remarkable, long-lasting relief of the first few patients, we therefore continued treating patients with clinical symptoms suggestive of a neuroma. We report on long-term pain relief after trigger point injections (TPI) for women with PMPS.

**Methods:** An observational cohort study of women with PMPS and clinical evidence of neuroma was undertaken. Patients were examined by breast surgeons at a single institution. We injected a 2mL mixture of equal parts 0.5% bupivacaine and 4 mg/mL dexamethasone into each trigger point. Demographics, type of breast and axillary surgery, duration of pain, history of surgical complications, adjuvant radiotherapy, number of injections required, location of trigger points and dates of injection were obtained from the electronic medical record. Patients were surveyed via telephone interview for long-term resolution of pain. Descriptive statistics are reported, univariate and bivariate analyses were conducted using Stata 12 (College Station, TX).

**Results:** We identified 89 trigger points on 61 breasts in 53 patients with PMPS. Patient age ranged from 30-92 years. Mean number of surgeries prior to injection was 2.2 (range 1-8). In this cohort, we found mastectomy was the most frequent surgical procedure preceding the development of a neuroma (41 breasts), followed by reduction mammoplasty with or without concurrent partial mastectomy (16 breasts), and least frequently lumpectomy alone (4 breasts). The time from the onset of neuropathic pain to the first trigger point injection varied from as early as 1 week post-operatively to 132 months (mean 22.2 months). Effectiveness of the TPI was assessed by physical examination immediately (1-3 minutes) after the injection, then with telephone interview (at ≥3 months post TPI). All 53 patients had long-term follow-up data (≥3 months). Long-term relief was achieved in 84 of 89 trigger points (94.4%) or 54 of 61 breasts (88.5%). Trigger point injections were well tolerated by all patients and no complications were reported.

**Discussion:** Perineural infiltration with bupivacaine and dexamethasone is a safe, simple, and effective treatment option for PMPS with an associated trigger point. Our data suggest this significant problem can easily be resolved in an outpatient setting. All breast specialists should inquire about the presence of symptoms consistent with PMPS and understand the value of intervention to eliminate neuropathic pain. This technique should be added to the armamentarium of all surgeons who perform breast surgery.
Subjective and objective assessment of efficacy of frozen gloves and socks to prevent nab-paclitaxel-induced peripheral neuropathy in patients with breast cancer

Toshinari Yamashita¹, Masaya Hattori², Takumi Nakada³, Takako Hayashi⁴, Keitaro Kamei⁵, Toyama Tatsuya⁶, Yasuko Nagao⁷, Takahiro Mase⁸, Masaki Wada⁹, Toshio Mizuno¹⁰, Kojiro Shimozuma¹¹, Hiroji Iwata² and Takuhiro Yamaguchi¹².

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a frequent side-effect of taxanes which play a central role in the treatment of breast cancer. CIPN can negatively influence long-term quality of life, warranting the development of effective prevention strategies. This study investigates the efficacy of frozen gloves and socks (FGS) in reducing the incidence and severity of nab-paclitaxel-induced peripheral neuropathy. Endpoints were evaluated using both clinician and patient reports.

Methods: This is a multicenter phase II single arm trial study of the effects of FGS for advanced or metastatic breast cancer patients receiving nab-paclitaxel (260 mg/m²) every 3 weeks. Patients wore FGS on their diseased side hand and foot for 60 min during infusion. The other side acted as the untreated control. CIPN was assessed using Patient Neurotoxicity Questionnaire (PNQ), PRO-CTCAE and CTCAE at baseline and every cycle of nab-paclitaxel. The primary endpoint was the incidence of CIPN assessed by PNQ (grade C or higher) after receipt of up to 4 cycles of nab-paclitaxel.

Results: Between September 2012 and January 2015, 50 patients from 16 sites were enrolled in this study. Of 50 patients, 27 (54%) received at least 4 cycles of nab-paclitaxel. There was a trend for the incidence of CIPN assessed by PNQ and PRO-CTCAE to be lower in the intervention side than in the control side, although this difference was not statistically significant. The incidence of CIPN assessed by CTCAE was significantly lower in the treated hand (Table).

Conclusions: Among breast cancer patients who received nab-paclitaxel, FGS produced favorable effects as detected by reduced clinician-reported CTCAE grades for CIPN, although the study did not detect differences in self-reported symptoms of CIPN using PRO-CTCAE or PNQ. Clinical trial information: UMIN000007907.

Palliative care and older women with advanced breast cancer in Mexico

**Background:** Mexico is an upper-middle income country, as other developing regions, there is an accelerated aging of the population that will double the absolute number of new breast cancer (BC) cases by 2035. Unfortunately, the incidence of stage III and IV in women older than 65 years old represented 45% of new cases (higher than high-income regions); also, 21% had diabetes, 41.1% hypertension and 71% overweight/obese. These factors make our older adults patients with BC a high-risk population of recurrence and dead from disease.

**Objective:** Describe the characteristics of older women with BC that received palliative care in a multidisciplinary setting.

**Patients and Methods:** A cross-sectional, retrospective, descriptive of 178 patients with advanced breast cancer, older than 65 years from our data based, that were referred to palliative service during 2010-2016 at National Cancer Institute, Mexico. Statistical analysis was done with STATA V12.0. We described clinical, pathological and sociodemographic characteristics of this older women with advanced BC and analyzed the risk factors that influence dead. Approval from IRB was obtained.

**Results:** The median age was 75 years old (range 69-82), 71(41%) was widows, 51(29%) had none education, 93(52%) had elementary school. Highlights that 93 (52%) of the patients evaluated had any income source. Diabetes was present in 43(24%), hypertension in 81 (46%) and cardiopathy in 17(10%) of cases. ECOG-2 were 58 (33%) patients, ECOG-3 was in 47 (26%) patients and ECOG-4 was reported in 19 (11%). None patient had geriatric assessment. Affected metastasis sites were bone 90 (51%), lung 66 (37%), central nervous system 31 (17%), liver 27 (15%). 69 (62%) patients had hormonal receptor positive, 17 (15%) triple negative, 12 (11%) HER2 positive and 13(12%) of the cases were triple positive, 41 (74%) patients had Ki-67 higher than 50%. Polypharmacy was identified in 77 (43%) of the patients. The median survival after the admission in the palliative service was 2 months (IQR 0-10). After a logistic regression univariate Ki-67>20% (OR 10.25), triple negative (OR 1.5), HER2 positive (OR 2.3), influence negative survival.

**Conclusions:** Management of BC in the elderly is complex. Our data show that we have highly vulnerable population. Additionally, we found an unfortunate late reference to palliative care services that limited the impact of the multidisciplinary approach. We need to identify the barriers that influence this delay. Health care providers have a challenge in early reference of older women with advanced breast cancer patients to the palliative care and need to think in integrate to the multidisciplinary team a geriatrician with oncology perspective.
Opioid prescriptions in the military health system breast cancer population, FY2007 – FY2014

Diana D Jeffery1, Laura Hopkins2, Christopher J Spevak3 and Harry B Burke4. 1Department of Defense, Defense Health Agency, Medical Affairs, Clinical Support Division, Falls Church, VA; 2Kennell and Associates, Inc., Falls Church, VA; 3Department of Defense, Defense Health Agency, Walter Reed National Military Medical Center, Bethesda, MD and 4Department of Defense, Uniformed Services University of the Health Sciences, Bethesda, MD.

Purpose: Opioid use among individuals with breast cancer is a safety concern because of adverse events including misuse, overdose, and death. To date, there are two published U.S. population-based studies of opioid use among breast cancer patients, both which address persistent opioid use after surgery. Here, we examine rates, amount, and cost of opioids prescribed to breast cancer patients over an 8-year period.

Methods: We used Military Health System (MHS) outpatient, inpatient, and pharmacy claims data to select beneficiaries with a primary diagnoses of breast cancer, fiscal years (FY) 2007-2014. Logistic regression models were used to identify predictors of having received ≥1 opioid prescription within a year, and having received >4 filled opioid prescriptions within a year. Simple linear regression and multiple regression were used to examine trends and predictors of reimbursed opioid cost.

Results: Among 25,500 non-elderly breast cancer patients treated in the MHS each year, most were age 55-64, located in the southern U.S., and treated in civilian facilities only. On average per year, 75% had surgery, 90% radiation therapy, 19% chemotherapy, and 8% hospice care. Annual rates of receiving ≥1 opiate prescription were stable across 8 years, 48.1% (FY2007) to 50.5% (FY2012 and FY2013). The annual number of opioid prescriptions per patient was also stable, 4.26 (FY2014) to 4.39 (FY2007). Average reimbursed cost of opioids steadily increased over time, $135 (FY2007) to $260 (FY2014) (p < 0.001).

Based on regression models, the strongest predictors (p < 0.001) of having received ≥1 opioid prescription were (in order of statistical significance): surgery, chemotherapy, civilian care only or mixed use civilian and military care, number of physical comorbid conditions, hospice use, and depression. The strongest predictors (p < 0.001) of >4 opioid prescriptions per year were: depression, hospice use, number of physical comorbidities, and chemotherapy, followed by anxiety disorder, alcohol use disorder, and drug use disorder. The strongest predictors (p < 0.001) of high reimbursed opioid cost were: drug use disorder, hospice use, depression, civilian care only or mixed use civilian and military care, alcohol use disorder, number of physical comorbid conditions, receipt of chemotherapy, fiscal year, and anxiety disorder.

Discussion: Half of individuals with a primary breast cancer diagnosis receive ≥1 opioid prescription per year. Four overlapping constructs predict opioid prescriptions and cost: treatment modalities, physical and mental health comorbidities, severity of illness, and system of care. Increased cost over time coincides with current U.S. population reports suggesting rising daily opioid dosage. Despite limitations with claims data, the results suggest that opioid use among breast cancer patients need to be monitored and accompanied by documented clinical management plans. We recommend that oncology providers implement risk reduction strategies including screening for history of substance use and mental health comorbidities, and implementing guidelines specific for cancer patients such as those found in the Veterans Administration/Department of Defense Clinical Practice Guidelines for Opioid Therapy for Chronic Pain, v. 3.0.
Factors associated with accepting chemotherapy despite the risk of fertility loss in Latin American breast cancer patients (LACOG 0414 FERTILITY study)

Gustavo Werutsky¹, Cynthia Villareal-Garza²,³, Henry G Moreno⁴, Alfredo A Cartagena⁵, Saul Campos-Gomez⁶, Rosa O Reyes⁶, Juan J Lence⁶, Pedro Liedke⁸, Tomás Reinert⁹, Monique Binotto⁹, Vanessa Dybal¹⁰, Jeovany Martinez-Mesa¹, Raquel DS Freitas¹, Paulo Ricardo Nunes Filho¹, Facundo Zaffaroni¹ and Carlos HE Barrios¹,¹¹. ¹Latin American Cooperative Oncology Group, Porto Alegre, Brazil; ²Instituto Nacional de Cancerología, Mexico City, Mexico; ³Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru; ⁴Oncosalud, Lima, Peru; ⁵Centro Oncológico Estatal, Instituto de Seguridad Social del Estado de México y Municipios, Toluca, Mexico; ⁶Instituto Nacional de Oncología Y Radiobiología, Havana, Cuba; ⁷Breast Cancer Center, Tecnologico de Monterrey, Monterrey, Mexico; ⁸Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; ⁹Centro de Pesquisa e Educação da Serra Gaúcha, Caxias do Sul, Brazil; ¹⁰Clínica Assitência Multidiscilinar em Oncologia, Salvador, Brazil and ¹¹Centro de Pesquisas em Oncologia, Porto Alegre, Brazil.

BACKGROUND
Breast cancer (BC) is the leading cause of cancer-related morbidity in young women in Latin America. For young patients, chemotherapy induced ovarian failure is a relevant issue, as evidence suggests that young patients with BC experience greater psychological distress and anxiety due to concern for future fertility. Nevertheless, reports from Europe estimated that 95% of patients accepted chemotherapy despite infertility risk. In this study we aim to evaluate the factors associated to the probability of accepting (neo)adjuvant chemotherapy for stage I-III BC despite the risk of fertility loss in young BC patients in Latin America.

METHODS
Prospective cohort study conducted in 8 sites from Brazil, Mexico, Cuba and Peru. We included pre-menopausal women from 18 to 40 years-old, with stage I-III BC and indication of (neo)adjuvant chemotherapy. Before chemotherapy administration, patients answered a short, previously pilot-tested questionnaire comprising 8 questions related to pregnancy history and fertility loss awareness. Association between explanatory variables and the outcome variables was assessed using logistic regression.

RESULTS
Overall, 301 patients completed the fertility questionnaire, 48.5% (N=146) from Mexico, 34.9% (N=105) from Peru, 10% (N=30) from Brazil and 6.6% (N=20) from Cuba. Median age at diagnosis of BC was 34 years old, 84% completed second or higher degree of education, 61% were married and 71.4% had children prior to cancer diagnosis. Clinical stage was I in 10.6%, II in 55% and III in 32.4%. Overall, 85% of patients agreed to undergo chemotherapy despite the risk of fertility loss, 51.3% of patients would like to have children in the future and 32% did not want to have children due to BC diagnosis. 66.3% of patients knew that chemotherapy could reduce their fertility, however 85% would agree to receive it if they know about the risks. Factors associated with higher probability of accepting chemotherapy in univariate analysis were stage II and III vs. I (OR 1.39 and 2.38 respectively, P = 0.0023, single marital status (OR 10.65, P = 0.0235), previous children (OR 3.18, P = 0.0251) and unwillingness of having more children in the future (OR 5.0, P = 0.0138). However, in the multivariate analysis, the only factor associated with accepting chemotherapy despite the risk of fertility loss was being single (OR 10.8 95% CI 1.4 – 83.6; P = 0.023). Also, most patients (75%) would consider the use of chemotherapy in case of more than 20% improvement in cure rates, and 36.2% even if the maximum risk of fertility loss was from 76 to 100%.

DISCUSSION
In our study, we identified a lower probability of accepting chemotherapy due to infertility risk than previous reported in the literature from Europe, despite the younger age of patients and worse stage at diagnosis. Moreover, most patients desired a larger benefit of (neo)adjuvant chemotherapy than usually seen in clinical trials in order to accept chemotherapy. Access to fertility preservation strategies is a need for young BC patients in Latin America.

KEYWORDS: Breast Neoplasms; Fertility Preservation; Antineoplastic Agents; Treatment Adherence and Compliance
Age-related distress in 3352 breast cancer patients

Addie Hill\textsuperscript{1}, Richard Obenchain\textsuperscript{1}, Karen Clark\textsuperscript{1}, Matthew Loscalzo\textsuperscript{1} and Joanne Mortimer\textsuperscript{1}. \textsuperscript{1}City of Hope Medical Center, Duarte, CA.

Purpose: Age-related biopsychosocial distress in breast cancer patients has been poorly studied and understood. The breast cancer experience may be different based on chronological age, which may be a surrogate marker of biologic, psychological, social, and functional age. This study reports patient-reported biopsychosocial problem-related distress in breast cancer patients.

Methods: All new patients seen at the City of Hope breast cancer clinic undergo a validated comprehensive biopsychosocial screening prior to their first visit with a medical/surgical oncologist. This touchscreen driven technology queries patients on their physical symptoms, psychosocial concerns, informational and resource needs, interests in clinical trials, and other breast cancer specific concerns. This IRB approved study was conducted in 3,352 patients evaluated from 2009 to 2017. Screening occurred immediately prior to meeting with the physician so that the information could be integrated into the clinical encounter.

Results: The age-related groups included 268 Adolescent and young adult (AYA) patients ages 18-39, 2,244 middle aged adults 40-64 years, and 840 older adults ages 65+ years. Regardless of age, four of the top seven highly distressing problems were the same: worry about the future, side effects of treatment, sleep and fatigue. AYA patients and middle aged adults, but not older adults, identified finances and being anxious or fearful among their top five causes of distress. Middle aged adults and older adults, but not AYA patients, identified physical pain among their top seven causes of distress. Interestingly, both AYA and older adults, but not middle aged adults, identified getting information about complementary and alternative practices as a top source of distress. Although a serious problem across all age categories, thoughts of ending one’s life and seriously considering taking one’s life were the least common problems identified.

Conclusions: In this series with 3,352 patients, biopsychosocial concerns raised with a diagnosis of breast cancer were similar regardless of age. However, patients under the age of 65 may worry more about finances and patients over the age of 40 may worry more about physical symptoms such as pain. Both AYA patients and older adults cited distress learning about complementary and alternative practices, suggesting a need for providers to address this, especially in these patient populations. Thoughts of ending one’s own life were uncommon, which is relevant in a state with the End of Life Option Act.
Introduction
Adjuvant chemotherapy is one of the outstanding treatments in the treatment of breast cancer. Many of its side effects are well known, while others are under study, as cognitive impairment.
One/eight women have breast cancer, which often affects a young population. Cognitive disorders produced by chemotherapy were studied with controversial results.
It seems convenient to study whether chemotherapy produces a cognitive impairment in a homogeneous group of patients receiving adjuvant chemotherapy with concomitant anthracycline cyclophosphamide followed by weekly paclitaxel (AC-T) in a prospective design.

Methods
Included patients had early-stage breast cancer (Stage I-II) and received AC-T (Anthracycline 60 mg/sqm - cyclophosphamide 600 mg/sqm and sequential weekly paclitaxel 80 mg/sqm) following surgery and before radiation therapy, as indicated. Her 2 positive patients also received adjuvant Trastuzumab therapy.
The cognitive deficit was estimated through the Addenbrooke’s Cognitive Examination test, taken the day of the beginning of treatment, and at 3, 6 and 12 months later.
Beck Depression Inventory Test was used to assess depression. It was taken at the beginning of treatment and at 12 months later.
Control group was built by healthy people, which were examined with the same test just once.

Results
From October 2016 to April 2014, 108 patients were included in chemotherapy group and 50 in a healthy control group. 51 patients completed 12 months follow up examination.
Significant differences were found between patients and control group in attention, concentration, verbal fluency, language, visuospatial abilities and memory parameters.
These parameters were found impaired at the beginning of the treatment, having a favorable evolution at twelve months, with a complete resolution.
Orientation did not suffer significant changes during all study.
27/108 patients were found to be depressed at the beginning of treatment, with a favorable evolution of this parameter at twelve months.
Control group did not suffer from any cognitive deficit or depression.

Conclusions
In this prospective study, patients suffered cognitive deterioration at the beginning of treatment, which was recovered at the twelve-month follow-up.
Given the prevalence of depression in the chemotherapy group patients at the beginning of treatment versus the control group, this is probably the cause of the cognitive disorder.
Use of complementary and integrative medicine therapies in Chilean patients with breast cancer. Experience of a private center: prevalence and characteristics of patients

Claudio Salas¹, Gabriel Lopez², Fernando Cadiz¹, Carolina Barriga¹, Pilar Gonzalez¹, Sandra Acevedo¹, Patricia Raimilla¹, Pia Pincheira¹, Aung Naing² and Marta Quiroga¹. ¹Clínica Alemana de Santiago, Santiago, Region Metropolitana, Chile and ²MD Anderson Cancer Center, Houston, TX.

Background: During the last decade several studies have been reported that the use of complementary and integrative medicine (CIM), defined as health care methods generated outside of standard Western, or conventional clinical practices has been increasing among breast cancer patients in developed countries. However, there is little information about the use of CIM in developing countries. Chile currently has no published statistics on the use of CIM in breast cancer.

Methods: We conducted a cross-sectional survey between March and June 2017 in breast cancer patients treated in Clinica Alemana de Santiago to determine the prevalence of CIM use and the types of preferred CIM. We also analyzed associations between CIM and several variables including sociodemographic variables, the reasons that motivated the use of CIM and the subjective benefits that patients attributed to CIM. Statistical analysis included two tailed t–test for continuous variables, Fischer's exact test for categorical variables and logistic regression for association between CIM use and other variables.

Results: 288 patients answered the survey. Among them, 98.9% were women, mostly between 41 and 50 years (40.4%). 44.9% (n = 129) reported using CIM. No association was found between the use of CIM and sociodemographic variables (sex, age, education, income). Most used CIM types were: vitamins / minerals (50.4%), herbs (48.8%), special diets (42.6%), meditation/prayers (37.2%). The reasons for CIM use were "to do everything possible" (72%), "improve immunity" (67.8%), "reduce side effects of treatment" (32.7%), recommendation by family member or friend (32.7%). Regarding CIM habits, 50.8% of patients reported having started CIM use at the time of diagnosis and only 51.6% reported about CIM use to their attending physician. Most patients reported benefits associated to CAM use (61%) but no differences were found in reported quality of life.

Conclusions: Great amount of the patients reported using CIM and half of them mentioned that they shared this information with their attending physician. It is necessary incorporate to medical routines questions regarding CIM use and to educate the patients regarding the safe use of CIM and the possible interactions of these approaches with conventional clinical practices.
First implementation of the International Consortium of Health Outcomes Measurement standard for breast cancer at a major German university hospital using a web-based tool to measure patient reported outcomes

Maria M Karsten¹, Dorothee Speiser¹, Claudia Hartmann², Kai Lippold², Valerie Kirchberger³ and Jens-Uwe Blohmer¹. ¹Klinik für Gynäkologie mit Brustzentrum, Charité Universitätmedizin Berlin, Berlin, Germany; ²Ärztliches Direktorat, Charité Universitätmedizin Berlin, Berlin, Germany and ³Strategische Unternehmensentwicklung Value Based Health Care, Charité Universitätmedizin Berlin, Berlin, Germany.

Purpose:
Collecting patient reported outcome (PRO) data in a systematic way enables an objective evaluation of treatments and its related outcomes. By using the disease specific questionnaires developed by the International Consortium of Health Outcome Measurement (ICHOM) this allows for comparison between physicians, hospitals and even different countries.

Methods
In November 2016 we implemented a web-based system to collect PRO data at the breast center at Charité University hospital using the ICHOM data set. All new patients who are seen at the breast center are enrolled and are answering a predefined set of questions using a tablet computer. Once they start their treatment at Charité automated emails are sent to the patient at predefined treatment points. Those emails contain a web-based link through which they can access their questionnaires.

Results
Until now we have enrolled 834 patients and initiated 2470 questionnaires. 9.44% of patients were under 40 years of age, 49.7% between 40 and 60, 39.6% between 60-80 and 1.3% over the age of 80 years. The average return rate of questionnaires is 72% without any additional intervention. When asked about preference regarding paper versus online 7.9% of the patients 50 to 60 years of age would prefer paper, 18% in the 60-70 years of age group and 21.2 % in the age group over 70 years.

Conclusion
Measuring PRO in breast cancer patients in an automated electronic version is possible across all age ranges while simultaneously achieving a high return rate.
Quality of life, fatigue, and subjective cognitive functioning immediately and 6 months after adjuvant chemotherapy in breast cancer patients

Jeroen Mebis1,2,3, Sandrine Censabella1, Sofie Engels1, Caroline Van Marsenille1, Guy Orye1, Sofie Marquette1, Leen Vansteelandt1, Daisy Luyten1,2, Annelies Maes1,2, Leen Noé1,2 and Paul Bulens1,2. 1Jessa Hospital, Hasselt, Belgium; 2Limburg Oncology Center, Hasselt, Belgium and 3Faculty of Medicine and Life Sciences, Hasselt University, Diepenbeek, Belgium.

Background
The aim of this study was to examine quality of life (QoL), fatigue, and subjective cognitive functioning (SCF) after chemotherapy in breast cancer (BC) patients.

Methods
BC patients were recruited before chemotherapy (3 FEC+3 Tax, BC-Chemo) and compared with disease-specific controls (i.e., BC patients not receiving chemotherapy, BC-Controls) and healthy controls (HC) matched for age and education.

All participants completed questionnaires assessing QoL (using the Functional Assessment of Cancer Therapy – General Population), fatigue (using the Functional Assessment of Chronic Illness Therapy-Fatigue), and SCF (with the Cognitive Failure Questionnaire) at recruitment and 6 months later (i.e., one month after the end of chemotherapy). Follow-up data (1 year after recruitment) were available for BC-Chemo and HC only.

Difference scores were computed for each participant (i.e., score after 6 months/1 year minus score at baseline) and transformed when necessary so that negative scores would reflect decline over time (i.e., decreased QOL, increased fatigue, and increased cognitive complaints). These difference scores were analysed using independent t-tests (BC-Chemo vs BC-Controls on one hand, and BC-Chemo vs HC on the other hand).

Results
Eighteen BC-Chemo, 19 BC-Controls, and 20 HC completed the study (mean age = 49, 58, and 44 years, resp., p = 0.001, BC-Controls being significantly older).

Statistical analyses showed that, after chemotherapy, BC-Chemo patients showed significantly lower QoL, more fatigue, and declined SCF than both groups of controls (see Table 1).

However, 6 months later, no statistically significant differences were found between BC-Chemo and HC with respect to QoL and fatigue. Only SCF remained significantly lower in BC-Chemo.

Table 1. Mean Scores (standard deviations) for Quality of Life (QoL), Fatigue, and Subjective Cognitive Functioning (SCF) in Breast Cancer Patients treated with Chemotherapy (BC-Chemo) or not (BC-Controls) and Healthy Controls 6 months and 1 Year After Baseline

</table>

*p < 0.05 (two-tailed independent t-tests vs BC-Chemo). Note. FACT-GP: Functional Assessment of Cancer Therapy – General Population (higher scores = greater QoL). FACIT-F: Functional Assessment of Chronic Illness Therapy-Fatigue Scale (higher scores = greater fatigue).
scores = low fatigue). CFQ: Cognitive Failure Questionnaire (higher scores = greater subjective cognitive problems). All difference scores reflect decline over time.

Conclusions
Shortly after chemotherapy (i.e., 6 months after baseline), breast cancer patients experienced diminished QoL and increased fatigue compared to both disease-specific and healthy controls, but these differences were no longer significant 6 months later. In contrast, group differences in SCF were significant at both timepoints, suggesting long-lasting cognitive decline for patients receiving chemotherapy.
Patients' preferences for postmenopausal hormone receptor-positive (HR+), human epidermal growth factor receptor 2 negative (HER2-) advanced breast cancer treatments in Japan

Yukie Omori¹, Sotaro Enatsu¹, Zhihong Cai¹ and Hiroshi Ishiguro². ¹Eli Lilly Japan K.K., Kobe, Japan and ²International University of Health and Welfare, Narita, Chiba, Japan.

**Background:** The objective of this study was to identify factors that affect preferences for treatment of breast cancer (BC) patients in Japan and understand their relative importance. Also this study explored whether patients' sociodemographic and clinical characteristics would affect patient preference in choice of treatment. **Methods:** A questionnaire for discrete choice experiment (DCE) was developed with five attributes, progression free survival (PFS), incidence of diarrhea (IOD), frequency of diarrhea (FOD) which represents the increase in the number of stools per day than usual, duration of diarrhea (DOD) and route and frequency of administration (RFA) referring MONARCH 2, a global phase III study for abemaciclib plus fulvestrant versus placebo plus fulvestrant in patients with HR+/HER2− advanced BC. Each questionnaire was composed of nine choice sets and each choice set contained those five attributes with different levels. Postmenopausal and HR+ BC patients in Japan who recruited from a patient panel were asked to choose one treatment alternative in each choice set. Conditional logit model was used to identify relative preferences of each attribute. The preference weights were evaluated with βcoefficient and standard error. In addition, conditional logit model including patient-specific covariates, such as patient characteristics (age, employment status, age of children and marital status) and clinical characteristics (experience of relapse or metastasis and with/without hormone sensitivity), was used to identify factors that affect patient preference in choice of treatment. **Results:** Of 302 respondents recruited, 258 had valid responses and the rest had inappropriate answers for the validity testing choice set. The mean age (SD) was 56.7(6.7), 47.7% had paid employment, median duration since diagnosis was 5.1 years and 98.1% had experienced hormonal therapy. According to the absolute magnitude of coefficients, when the FOD is 6, the order of attributes' relative importance was the following: PFS, DOD, FOD, IOD, RFA. However when the FOD becomes 9, FOD was the most important attribute for patients. All tested attributes were statistically significant (p<.0001) on their preference in choice of treatment. When patient-specific covariates were included in the model, the patients who have had experience of relapse or metastasis showed the strongest preference for the longest PFS of 16 months and the patients who were 45 to 59 years old showed the weakest preference for the highest FOD of 9. **Conclusions:** Postmenopausal and HR+ BC patients in Japan showed preference for treatments which can extend PFS even with the potentiality of Grade 2 diarrhea by the grading of Common Terminology Criteria for Adverse Events v4.0. Prevention of diarrhea to make it Grade 2 or lower may maintain patients' motivation for the treatment which can extend PFS. This study also showed that patients' sociodemographic and clinical characteristics tend to affect patients' treatment choices. It will be important to choose treatments with considering patients' characteristics such as their life style, age and therapeutic experience.
Patients' and surgeons' experiences after failed breast reconstruction: A qualitative study

Casimir AE Kouwenberg¹, Lothar E Hoogdalem², Jessica P Gopie³, Aad Tibben³, Marc AM Mureau¹, Sohal Y Ismail² and Leonieke W Kranenburg². ¹Erasmus MC Cancer Institute, University Medical Centre Rotterdam, Rotterdam, Netherlands; ²Section Medical Psychology and Psychotherapy, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands and ³Leiden University Medical Centre, Leiden, Netherlands.

Background: Breast cancer reconstructive surgery is supposed to contribute to patients' body image and quality of life. However, complications after autologous breast reconstruction (A-BR) and implant-based breast reconstruction (I-BR) do occur in approximately 40% of the women, and may even lead to complete failure in rare cases. This study explores both patients' and surgeons' experiences after failed breast reconstruction. Increased knowledge in this field could help to improve not only the care for women with failed breast cancer reconstructive surgery but may also help to guide professionals in dealing with such failures.

Methods: Patients with reconstructive failure form a large multicenter cohort study and participating plastic surgeons were invited to participate in this study. A topic list consisting of ten topics served as a general outline of a semi-structured interview on their experiences with the reconstructive failure, lasting about one hour. The interview data were transcribed and after that analyzed according to the principles of grounded theory by two researchers independently of each other. Data were coded in NVivo software. Next, data were discussed in a larger team, thereby moving back and forth between data and emerging theory.

Results: Fourteen patients with a failed I-BR, four patients with failed A-BR and four plastic surgeons participated in this study. Three main categories emerged from the data: personal experiences, the motivation for a redo of the failed reconstructive surgery and patient-doctor communication. With regard to personal experiences, a main patient category was the importance of being (appreciated as) a person as a whole, in his/her specific context (versus focusing on reconstructive technique). This in contrast to the surgeons, for whom it did matter whether the failure concerned an I-BR or A-BR. The latter was perceived as more intense. Some took it as a personal failure, leading to insecurity and feelings of regret towards the patient. This was especially true if they felt a strong bond with that particular patient. With regard to motivation for a redo of the failed reconstructive surgery, both patients and surgeons emphasized the importance of shared decision making. Nevertheless, patients seemed to remain more ambivalent than surgeons about pursuing additional reconstruction after failure. Finally, regarding patient-doctor communication, we found that surgeons were more distant or reflective on these matters, whereas patients expressed their experiences in a more emotional way. Patients expressed a desire to be seen and treated as an unique individual. Experiencing trustfulness, sincerity and empathy from the surgeon in discussing the failure were highly valued.

Discussion: Implementing the results of this study in clinical practice may facilitate coping with the distressing or even traumatic event of failed breast reconstruction, in both patients and surgeons.
Endocrine treatment for hormone receptor-positive advanced breast cancer patients with endocrine-sensitive or endocrine-resistant disease: A systematic review and network meta-analysis

Mariana Brandão¹, Christian Maurer², Patrícia Ziegelmann³, Noam Pondé¹, Arlindo R Ferreira⁴, Samuel Martel⁵, Martine Piccart-Gebhart¹, Márcio Debiasi⁶, Evandro de Azambuja¹ and Matteo Lambertini¹. ¹Academic Promoting Team - Institut Jules Bordet and L'Université Libre de Bruxelles (U.L.B), Brussels, Belgium; ²University of Cologne, Cologne, Germany; ³National Institute for Health Technology Assessment (IATS), Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; ⁴Hospital de Santa Maria and Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal; ⁵CISSS Montérégie-Centre/Hôpital Charles-Le Moyne Centre Affilié de l'Université de Sherbrooke, Longueuil, Canada and ⁶Breast International Group, Brussels, Belgium.

Background: For patients with hormone receptor-positive (HR+) advanced breast cancer (ABC), the choice of endocrine treatment should be based on the best available evidence. However, no direct head-to-head comparison of all tested regimens is currently available. This network meta-analysis aims at providing detailed inference-based data to guide decision making on endocrine therapy for HR+ ABC patients in two different clinical scenarios: endocrine-sensitive and endocrine-resistant ABC, as defined by the ABC guidelines criteria.

Methods: Phase II/III randomized clinical trials published or presented up to June 15, 2018 and comparing two or more different endocrine treatments (with or without associated targeted therapies) for HR+, HER2-negative ABC patients were included, irrespective of treatment line. Relative treatment effects were pooled as hazard ratios (HRs) and modeled in a network meta-analysis using a Bayesian framework with fixed-effects models in order to infer the best approach. The main outcomes were progression-free survival (PFS) and overall survival (OS). Four separate analyses were carried out: PFS and OS networks in both endocrine-sensitive and endocrine-resistant populations.

Results: A total of 26 trials were included in this meta-analysis (N=11330 patients). In the endocrine-sensitive setting, 12 trials were included in the PFS network (N=5200 patients; 10 different regimens) and 3 trials in the OS network (N=1295; 3 regimens). In terms of PFS, the combination of Fulvestrant 500 mg (F500)+CDK4/6 inhibitors (CDKi) had a 80% probability of being the most effective treatment, followed by aromatase inhibitor (AI)+CDKi (17% chance of being the best approach). The HR for the comparison between F500+CDKi vs. AI+CDKi was 0.82 (95% credibility interval [CrI] 0.54-1.25). Regarding OS, the AI+CDKi approach had a 63% chance of being the most effective regimen, followed by F500 (36% likelihood) – the HR for the comparison between the two regimens yielded a HR of 0.93 (95% CrI 0.61-1.40). In the endocrine-resistant setting, 18 trials were included in the PFS network (N=6130; 20 regimens) and 7 in the OS network (N=2701; 10 regimens). For PFS, F500+CDKi had a 59% probability of being the most effective treatment, followed by F500+Everolimus (11% likelihood). The HR of the comparison between F500+CDKi vs. F500+Everolimus was 0.84 (95% CrI 0.57-1.25). In terms of OS, F500+FGFR inhibitors had a 29% chance of being the best treatment option, followed by AI+everolimus (24% likelihood) – the HR for the comparison of F500+FGFR inhibitors vs. AI+everolimus was 1.07 (95% CrI 0.36-3.18).

Conclusion: This network meta-analysis provides for the first time a comparison of all tested treatment options for HR+ ABC patients in both endocrine-sensitive and endocrine-resistant settings. In terms of PFS, F500+CDKi appears to be the best treatment option for both disease settings. As for OS, AI+CDKi is possibly the best choice for endocrine-sensitive ABC patients. Concerning endocrine-resistant disease, F500+FGFR inhibitors may be an effective regimen which should be further studied, while AI+everolimus remains the best available option in this setting.
Selective androgen receptor modulator RAD140 inhibits the growth of endocrine-resistant breast cancer models with defined genetic backgrounds

Ziyang Yu¹, Suqin He¹, Chris Miller¹, Jamal Saeh¹, Gary Hattersley¹ and Alison O'Neill¹. ¹Radius Health, Inc, Waltham.

Estrogen receptor α-positive (ER+) breast cancer is routinely treated with therapies targeting the ER axis. However, de novo and acquired resistance to the standard-of-care treatment occur in a significant subset of patients. Multiple mechanisms have been proposed for the resistance, among which genetic alterations to the coding gene of ERα, ESR1, have been extensively studied. Notably, ESR1 hotspot mutations within the ligand binding domain (LBD), novel fusion proteins consisting of the N-terminal domain of ER and the C-terminal domain of a partner gene, and ESR1 gene amplification have been found to be enriched in endocrine-resistant, metastatic breast cancers. Together these ER gene alterations present new challenges in the management of ER+ breast cancer and call for the development of new agents to supplement the current standard-of-care. Around 90% of the ER+ breast cancer cases are also androgen receptor (AR) positive (AR+). Mounting preclinical evidence has demonstrated that AR agonists suppress AR and ER positive (AR/ER+) breast cancer cell growth, in line with clinical activity of androgens. We recently reported the oral selective androgen receptor modulator (SARM) RAD140 is a potent, tissue-selective AR agonist in breast cancer cells which significantly inhibited the growth of AR/ER+ patient-derived xenograft (PDX) models, partly via inhibiting ESR1 gene expression and ER signaling. It also elicited enhanced tumor growth inhibition when combined with a CDK4/6 inhibitor.

Here we further examine the activity of RAD140 in AR/ER+ breast cancer models that are endocrine-independent with a spectrum of ESR1 genetic alterations. In PDX models harboring ESR1 amplification or fusion, RAD140 inhibited tumor growth to a greater degree than fulvestrant, a standard-of-care selective ER degrader (SERD). These results are consistent with the clinical history of the donor patients whose diseases relapsed from or progressed rapidly on fulvestrant. In PDX models with ESR1 Y537S mutation, RAD140 showed anti-tumor activity comparable to that of fulvestrant. Notably, RAD140 treatment also led to substantial reduction of proliferation and colony formation in cell line models recapitulating resistance to the combination of estrogen deprivation and CDK4/6 inhibition.

In summary, RAD140 showed marked anti-tumor activity in AR/ER+, endocrine-resistant breast cancer models with defined genetic background. Importantly, in models with ESR1 amplification and fusion, the AR-targeting RAD140 exhibited more profound inhibitory activity compared with fulvestrant. In models with an ESR1 mutation, the efficacy of RAD140 and fulvestrant was comparable. These results lend support to a clinical hypothesis that AR/ER+, endocrine-resistant tumors with these genetic backgrounds may benefit from AR agonist-based treatment. RAD140 is currently being evaluated in hormone receptor positive (HR+) breast cancer patients (NCT03088527).
Elacestrant (RAD1901) demonstrates anti-tumor activity in models resistant to CDK4/6 inhibitors

Hitisha Patel¹, Nianjun Tao¹, Heike Arlt¹ and Teeru Bihani¹. ¹Radius Health, Inc, Waltham.

Background: Approximately 75% of all breast cancers diagnosed are estrogen receptor-positive (ER+) and currently approved endocrine therapies rely heavily on blocking of the ER signaling pathway. In recent years, the combination of an endocrine agent with other targeted agents have been evaluated to address endocrine resistance and improve progression-free survival (PFS). Recently, it was demonstrated that the addition of a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor to an endocrine agent roughly doubles PFS, leading to the approval and use of certain CDK4/6 inhibitors in combination with either aromatase inhibitors in the first-line metastatic setting or in combination with the selective estrogen receptor degrader (SERD), fulvestrant, in the second-line metastatic setting. While combining CDK4/6 inhibitors and endocrine therapy can result in significantly increased PFS, patients eventually progressed on these combinations, and to date, there is no cure for patients with advanced metastatic ER+ breast cancer. Given the increased use of CDK4/6 inhibitors in the ER+ breast cancer treatment paradigm, it will be important to understand how treatment resistance to CDK4/6 inhibitors manifests in order to optimize therapeutic strategies to target this patient population. We have previously described elacestrant (RAD1901), a novel and orally bioavailable SERD, as an inhibitor of ER+ breast cancer growth in in vitro models and in vivo patient-derived xenograft (PDX) models. Importantly, elacestrant inhibited the growth of PDX models that were derived from heavily pretreated patients, models harboring mutations in ESR1, and models insensitive to standard of care endocrine therapies. Given these results, we hypothesized that elacestrant would have anti-tumor activity in a CDK4/6 inhibitor-resistant setting. Herein, we describe elacestrant activity in multiple in vitro and in vivo models of CDK4/6 inhibitor resistance in both wild-type and mutant ESR1 backgrounds.

Methods: In vitro models of estrogen-independent ER+ breast cancer, harboring either wild-type or mutant ER, were exposed to increasing concentrations of approved CDK4/6 inhibitors: palbociclib, ribociclib, or abemaciclib. ER expression/signaling, changes in cell cycle mediators, and the effects of elacestrant and other SERDs were examined in these representative models. Results: Despite prolonged exposure to CDK4/6 inhibitors, the resistant cell lines retained ER, ER signaling, and importantly, ER-driven proliferation. Elacestrant induced dose-dependent growth inhibition in CDK4/6 inhibitor-resistant cells, and this effect was independent of the CDK4/6 inhibitor used to generate resistance. Elacestrant also demonstrated in vivo tumor growth inhibition of CDK4/6 inhibitor-resistant ER+ PDX models.

Conclusions: Our preclinical data demonstrate that elacestrant is a SERD that can inhibit tumor growth in a CDK4/6 inhibitor-resistant setting and provides rationale for examining elacestrant in patients that have progressed on a combination of endocrine therapy with a CDK4/6 inhibitor.
Time-to-treatment change for high-dose fulvestrant (HD-FUL) as first-line therapy in HR+ve, HER2-ve advanced pre-treated breast cancer (ABC) patients (pts): The real-world data from the GIM-13 AMBRA study

Stefano, Prato, Italy; 18Az. Osp. Reggio Emilia, Reggio Emilia, Italy; 19Università Cattolica del Sacro Cuore, Fondazione Policlínico ‘A. Gemelli’, Roma, Italy and 20Presidio Ospedaliero Civico e Benfratelli, Palermo, Italy.

Background
In Real World Studies (RWS), Progression Free Survival (PFS) could be not reliable as compared to randomized clinical trials (RCTs), due to the non-predefined times of disease evaluation. A potential surrogate of PFS for RWS could be TTC. We previously compared TTC of two different regimens (1st-line: Paclitaxel+Bevacizumab; any-line: Nab-Paclitaxel ) with the TTP results of the same regimens obtained in RCTs (Cazzaniga et al. J Clin Oncol 36, e13081, 2018; Mustacchi et al. J Clin Oncol 36, e13078, 2018), demonstrating that TTC is a valid surrogate end point of PFS in RWS. Aim of the present analysis is to describe pts’ characteristics and clinical outcome in terms of TTC in a population of endocrine-pretreated pts who received FUL as 1st-line therapy in a real-life setting.

Patients and Methods
We used data of the HR+ pts of the AMBRA study, a longitudinal cohort study, describing the choice of first and subsequent lines of treatment in HER2-ve MBC pts, treated with HD-FUL in 1st-line therapy to validate TTC for this population. Time parameters were estimated by the product-limit method, with failed observations censored to ‘1’. All statistical tests were two sided at the conventional 5% significance level. Analyses were carried out using NCSS® statistical software (V 12,Hintze J, Kaysville, UT, USA). The study had the approval of the Ethics Committees of the participating centers.

Results
So far AMBRA Gim-13 study enrolled 878 patients, 866 with known molecular subtype: overall, Luminal Tumors are 740 (85.45%). First Line HD-FUL was used in 91 patients (12.3%, median age at diagnosis was 57.8 years (35-82,2), median DFI 71,3 months (95%CI: 60.6-85.2); 36.5% of the pts relapsed while on 5-years adjuvant treatment. Fifty-four patients (59.3 %) had received adjuvant chemotherapy, 96.7% adjuvant endocrine therapy (Tamoxifen 13.6%; Tamoxifen followed by Aromatase Inhibitors 36.3%; AI 48.8%; in 7 cases in association with LHRH Analogs). Median follow up time from 1st Line start was 21,7 months (0 - 93,3). Bone and visceral metastases were present in 61 (67%) and 20 patients (21.9%) respectively. Median PFS of HD-FUL was 12.3 months (95%CI 8.7-13.93) in the whole population, 12.8 (range 2.9-47.7) and 9.16 (range 3-70) months in patients with bone and visceral disease, respectively. Median TTC was 11.2 months (95%CI 8.18-13.1). No difference with PFS was found (p= 0.92).

Conclusion
Median PFS observed in the GIM-13 AMBRA study is lower than that reported in FALCON (PFS: 16.6 months) and similar to the CONFIRM one (PFS: 5.6 months) trials. However, TTC and PFS are similar (p=0.92), so far confirming that the accuracy of data recording is quite correct. The present analysis shows that TTC is a reliable surrogate of PFS in RWS.
Evolving treatment patterns in hormone receptor-positive, HER2-negative metastatic breast cancer

Maria L Lankford¹, Susan L Britton¹, Arden D Buettner¹, Mitch Scharf¹, Brynn Tiscione¹, Joanne P Willey¹ and Reshma L Mahtani². ¹Xcenda, LLC, Palm Harbor, FL and ²Sylvester Cancer Center, University of Miami Health System, Deerfield Beach, FL.

Background: The last several years have seen the approval of multiple targeted agents for use alone or combined with standard endocrine therapies (ET) in the 1st, 2nd, and 3rd line hormone receptor positive (HR+), HER2 negative (HER2-) metastatic breast cancer (MBC) settings. Due to these new approvals, standards of care for treatment are evolving.

Methods: Prescribing preferences (PPrefs) of 592 U.S.-based medical oncologists were studied using a validated, proprietary, case-based market research tool (Challenging Cases®). Data were acquired using blinded, audience-response iPad technology at 8 live and virtual events during 2016-2018.

Two core hypothetical cases were presented: 1st line MBC and recurrent (REC) MBC. For each core case the following variables were introduced: time from completion of adjuvant (adj) therapy (Tx) to REC disease, site of metastases [visceral (VIS) vs non-visceral (N-VIS)], and age for the 1st line case, and type of metastases and line of Tx for the recurrent case. Rx choices for which there are published phase 3 data were offered, as well as a category for “other.”

Results:

In the setting of a patient (pt), age 63 with early REC on an adj AI, the most preferred strategy was FUL + a CDKi. In a pt, age 67, who completed 5 years of an adj AI with a TFI of 2 years, the most common preference was NSA1 + a CDKi. In an older pt (age 85) who completed 5 years of an adj AI and TFI of 2 years, the most common choice of TX was single agent ET. For a pt with N-VIS mets treated in the 2nd line setting, FUL + a CDKi was the most preferred strategy. In a 2nd line pt with REC at 12 mos on adj Tx and after 12 mos of 1st line Tx, FUL + a CDKi and EXE + EVE were the most preferred therapies. In a 3rd line pt, with VIS mets CT was the preferred choice.

**Conclusion**: Treatment patterns in HR+ HER2- MBC are evolving with the approval of several new agents and emerging data. Age, time to relapse, line of Tx, and type of mets may be some of the key factors that determine PPrefs in HR+, HER2- MBC.
Real-world experience using exemestane and everolimus in patients with hormone receptor positive/HER2 negative breast cancer with and without prior CDK4/6 inhibitor exposure

Sasha M Lupichuk¹, Ben Recaldin², Nancy A Nixon¹, Adriana Mututino¹ and Anil A Joy³. ¹Tom Baker Cancer Centre, Calgary, AB, Canada; ²Newcastle University, Newcastle, United Kingdom and ³Cross Cancer Institute, Edmonton, AB, Canada.

Background: For patients with metastatic hormone receptor (HR)-positive, HER2-negative breast cancer who progress on a non-steroidal aromatase inhibitor (NSAI), exemestane plus everolimus (EE) has been shown to prolong progression-free survival in comparison to exemestane alone. In the current era, many patients are now receiving a CDK4/6 inhibitor with first-line NSAI therapy. There is limited data describing the utilization and effectiveness of treatments following hormonal therapy - CDK4/6 inhibitor combinations, including EE. The aim of this study was to describe the real-world clinical experience and outcomes associated with EE amongst patients with and without prior CDK4/6 inhibitor exposure treated in our provincial jurisdiction.

Methods: All patients prescribed EE from January 1, 2016 through May 10, 2018 were obtained from the Alberta Health Services CancerControl Breast Data Mart (BDM). Patients with HER2+ disease, had received <1 cycle of EE or who had been on a placebo controlled trial of hormonal therapy +/- CDK4/6 inhibitor prior to EE were excluded. Review of the electronic medical record was undertaken to obtain detailed information on lines of treatment prior to EE, EE dosing and reason for EE discontinuation. The cohort was described and analyzed in total and by prior CDK4/6 inhibitor exposure. Time on treatment (TOT) was defined as start of EE to last dose or June 11, 2018 (censoring for data extraction) and was calculated using the Kaplan Meier method. The log rank test was used to compare TOT.

Results: There were 110 patients extracted and 88 eligible for analysis (3 excluded for HER2+ disease, 14 for receipt of <1 cycle EE and 5 for participation on a placebo controlled trial of hormonal therapy +/- CDK4/6 inhibitor prior to EE. Median age 62.4 years (range 32.1-86.6 years). EE was administered first line in 12.5%, second line in 46.6% and third or greater line in 40.9%. Median time from start of first line therapy to start of EE was 19.3 months (range 0.3-72.1 months). Visceral metastases at start of EE in 62.5%. EE mean starting dose 7.3 mg (SD 2.5 mg) and mean last dose recorded 7.0 mg (SD 2.7 mg). At time of data extraction, 69 patients had stopped EE, 68.1% for progression and 31.9% for toxicity or other reason. Twenty patients had hormonal therapy + CDK4/6 inhibitor prior to EE. In the first line setting, 10 patients had letrozole and palbociclib. In the second line setting or greater, 5 patients had letrozole + palbociclib, 1 patient had tamoxifen + palbociclib and 4 patients had fulvestrant + palbociclib. Median time on hormonal therapy + CDK4/6 inhibitor was 12.0 months (range 4.0-20.9 months). Those with hormonal therapy + CDK4/6 inhibitor were more likely to have visceral metastases (p=0.02). Median time on treatment for the CDK4/6 exposed vs naïve groups was similar (5.8 vs 5.3 months, p=0.952). Median overall survival not yet reached.

Conclusion: In a cohort of patients who have progressed on hormonal therapy + CDK4/6 inhibitor within 2 years, subsequent EE is a clinically meaningful treatment option in the setting of HR-positive/HER2-negative metastatic breast cancer. TOT was similar for CDK4/6 inhibitor exposed and naïve patients.
SEQUERPLUS: A multicenter real practice observational study investigating the endocrine-based (E) therapies sequential approach in hormonal receptor positive (HR+) HER2 negative (-) metastatic breast cancer (MBC)

Alessandra Fabi1, Diana Giannarelli1, Andrea Botticelli2, Simone Scagnoli3, Arianna Pellegrino4, Agnese Fabbri5, Domenico Corsi6, Valentina Magni3, Laura Pizzuti1, Ida Paris7, Vincenzo Bruni8, Roberta Pace9, Gaetano Lanzetta10, Simonetta Stani11, Luca Moscetti12, Paolo Marchetti2, Gabriele Piesco9, Francesco Cognetti1 and Valentina Rossi13. 1Istituto Regina Elena-IFO, Rome, Italy; 2S.Andrea Hospital, Rome, Italy; 3Policlinico Umberto I Hospital, Rome, Italy; 4San Pietro Hospital, Rome, Italy; 5Belcolle Hospital, Viterbo, VT, Italy; 6Fatebenefratelli Hospital, Rome, Italy; 7Policlinico Universitario A. Gemelli, Rome, Italy; 8Policlinico Campus Biomedico, Rome, Italy; 9San Camillo de Lellis, Rieti, Italy; 10Istituto Neurotraumatologico Italiano, Rome, Italy; 11Santo Spirito Hospital, Rome, Italy; 12Azienda Universitaria Ospedaliera of Modena, Modena, Italy and 13Breast Unit, S.Camillo-Forlanini Hospital, Rome, Italy.

Background: Despite the sequential E therapy is recognized as the preferred approach for HR+/HER2- MBC, no data from clinical trials support the choice between the different sequential strategies.

Methods: In this retrospective study descriptive statistics are reported using the median (Interquartile range, IQR) or frequency. Progression Free Survival (PFS) curves were estimated with the Kaplan-Meier method and compared with the log-rank test. Analysis were performed by SPSS version 21.0 (SPSS Inc., Chicago, IL).

Results: From January 2006 to December 2017, 240 patients (pts) with HR+/HER2- MBC receiving at least two consecutive E therapies as first approach were selected from 12 italian cancer centers. The median age at the time of metastasis onset was 63.5 (IQR: 55-72.5) years; 184 (76.7%) pts were in menopausal status; 38 (16%) had de novo stage IV disease and the remaining 202 (84%) had recurrent BC with a median time of 78 months (5-396 months). At the beginning of MBC diagnosis, 148 (62%) pts had a single site of distant disease, 108 (45%) of whom had bone only disease and 45 (18.8%) presented visceral involvement too. The aromatase inhibitor (AI) was chosen as I-line therapy in 146 (60.9%) pts, followed by Fulvestrant (F) in 62 (25.8%) pts; the alternative I-line options were everolimus-exemestane (Eve-Exe), tamoxifene (T), Palbociclib (P)+AI and F+AI in 13 (5.4%), 14 (5.8%), 1 (0.4%) and 4 (1.7%) pts, respectively. The most favourite II-line option resulted F for 111 (46.2%) pts while the Eve-Exe combination was chosen in 70 (29.2%) pts, AI in 30 (12.5%) pts; T, AI+F, P+F and antiprogestin were administered in 4 (1.7%), 4 (1.7%), 19 (7.9%) and 2 (0.8%) pts, respectively. For I and II-line, the AI followed by F (40%) and F followed by Eve-Exe (18%) were the most common sequential therapeutic approaches; the several alternative options were scanty used (in less than 10%). The median Progression-Free Survival (PFS) from first and second-line E therapies resulted 15.7 (95% CI 13.3-18.1) and 10.3 months (95% CI 8.7-11.9), respectively. Among 194 pts with disease progression after second-line E therapy, 87 (44.8%) received further E therapies with a median PFS 9.4 months (95% CI 7.9-10.9). The remaining 70 (29.2%) pts was treated with palliative chemotherapy. Interestingly, the median Overall Survival (OS) was even longer for pts receiving more lines of E therapies compared to the group with earlier introduction of chemotherapy (204.3 vs 92.8; p=0.007). Finally, in the subgroup analyses a longer PFS benefit was observed in pts with disease recurrence over 12 months from initial diagnosis (38.1 vs 30.3 months p=0.04) and limited sites of disease involvement at the time of MBC diagnosis (37.6 vs 28.3 months, p=0.03)

Conclusions: The sequential use in first and second-line setting of E therapies for HR+/HER2- MBC improves median PFS up to 32.3 months. According to real practice experience the optimal sequences could be AIs followed by F and F followed by Eve-Exe. A role for these compounds should be redefined in the light of recently introduction of CDK 4/6 inhibitors in combination with AIs or F for the first or later lines.
Time to treatment discontinuation of second-line fulvestrant monotherapy for HR+/HER2− metastatic breast cancer in the real-world setting

Patricia Luhn1, Carol O'Hear1, Thanh GN Ton1, Thibaut Sanglier2, Angela Hsieh1, David Oliveri3, James Chuo1, Yan Xiao2 and Leisha Emens4. 1Genentech, Inc., South San Francisco, CA; 2F. Hoffmann-La Roche Ltd., Basel, Switzerland; 3Genesis Research, Hoboken, NJ and 4Bloomberg–Kimmel Institute for Cancer Immunotherapy at Johns Hopkins, Baltimore, MD.

Background: Current treatment guidelines recommend sequential hormone therapy for patients with hormone receptor–positive (HR+) metastatic breast cancer (mBC) who are not in visceral crisis or who are not refractory to endocrine treatment. Second-line (2L) fulvestrant monotherapy is one option for patients with HR+ mBC that is human epidermal growth factor receptor 2 negative (HER2−) who progress on first-line (1L) treatment that may have included palbociclib. Using real-world data, we evaluated the differences in time to treatment discontinuation (TTD) of 2L fulvestrant monotherapy between groups of patients with HR+/HER2− mBC who did and did not receive 1L palbociclib.

Methods: Using a Flatiron Health EHR-derived database, we examined TTD of 2L fulvestrant monotherapy among 188 patients who progressed on 1L endocrine therapy. Eligibility criteria included a confirmed diagnosis of HR+/HER2− mBC between 1 Jan 2015 and 31 Oct 2017 and treatment with single-agent fulvestrant in the 2L metastatic setting. 2L fulvestrant monotherapy treatment was considered discontinued if (1) third-line (3L) treatment was initiated, (2) death occurred within 60 days of the last administration of 2L fulvestrant monotherapy, or (3) the duration between last administration of 2L fulvestrant monotherapy and last visit date was ≥ 60 days. Patients who did not meet this definition were censored. TTD was defined as the time from the first to the last administration of 2L fulvestrant monotherapy, the day before the 3L start date, death date, or the end of study (30 Apr 2018), whichever came first. TTD was estimated by Kaplan-Meier methods and stratified by previous use of 1L palbociclib. Log-rank test was used to test for differences.

Results: Overall, the median TTD of 2L fulvestrant monotherapy was 114 days (95% CI: 102, 127). For patients who previously received 1L palbociclib, the median TTD of 2L fulvestrant monotherapy was 102 days (95% CI: 85, 119) compared with 127 days (95% CI: 112, 141) for those who did not receive 1L palbociclib (log-rank P = 0.006). Patients who received 2L fulvestrant monotherapy and who had been previously treated with 1L palbociclib (n = 88) were more likely to be White (72.7% vs. 68.0%), younger (mean: 65.0 vs. 72.1 years), treated in an academic institution (9.1% vs. 4.0%), and experience longer median duration of 1L treatment (290.5 days vs. 211.0 days) compared with patients receiving 2L fulvestrant monotherapy who did not previously receive 1L palbociclib (n = 100).

Conclusions: In general, half of patients on 2L fulvestrant monotherapy discontinued treatment in < 4 months. Patients who previously received 1L palbociclib had shorter TTD of 2L fulvestrant monotherapy. Our data identify a potential area of unmet medical need for patients with HR+/HER2− mBC who are treated with fulvestrant monotherapy in the 2L setting and who previously received 1L palbociclib. Further investigation is warranted to examine whether observed results are driven by endocrine resistance or by confounding, selection, or channeling effects of new drugs.
Sequential second line endocrine therapy is still an effective strategy for postmenopausal ER+ and HER2- advanced breast cancer with low sensitivity to initial endocrine therapy

Kazuhiro Araki1, Tomomi Fujisawa6, Kentaro Sakamaki5, Yuichiro Kikawa3, Takayuki Iwamoto2, Takafumi Sangai9, Tadahiko Shien2, Shintaro Takao10, Reiki Nishimura11, Masato Takahashi8, Tomohiko Aihara1, Hirofumi Mukai7 and Naruto Taira2. 1Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; 2Okayama University Hospital, Okayama, Japan; 3Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; 4Breast Center, Aihara Hospital, Minoh, Osaka, Japan; 5Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; 6Gunma Prefectural Cancer Center, Otha, Gunma, Japan; 7National Cancer Center Hospital East, Kashiwa, Chiba, Japan; 8Hokkaido Cancer Center, Sapporo, Hokkaido, Japan; 9Chiba University Graduate School of Medicine, Chiba, Japan; 10Hyogo Cancer Center, Akashi, Hyogo, Japan and 11Kumamoto Shinto General Hospital, Kumamoto, Japan.

Background: It is unclear how to define responsiveness to endocrine therapy (ET) during the clinical course of advanced breast cancer (ABC), especially in evaluation of the effect of sequential ET. Objective: The goal of the study was to evaluate the efficacy of second line treatment of physician's choice (2nd-line TPC) for estrogen receptor-positive (ER+) and HER2-negative postmenopausal ABC with very low or low sensitivity to initial ET. Methods: A multicenter prospective observational cohort study was performed for 2nd-line TPCs. ABC with low sensitivity to initial ET was defined as recurrence within 5 years (yrs) during adjuvant ET or progression within 9 months (mo.) of initial ET. Similarly, ABC with very low sensitivity to initial ET was defined as recurrence within 2 yrs during adjuvant ET or progression within 3 mo. of initial ET. The expected clinical benefit rate (CBR: defined as patients who achieved CR, PR or SD for 24 weeks) was 50%. The null hypothesis of a CBR of 30% was tested with a one-sided α of 5%. 90% confidence intervals (CIs) were calculated for hypothesis tests. Results: A total of 56 patients (pts) were enrolled, but 7 were ineligible and one discontinued before starting the protocol treatment. The median age was 66 yrs (range: 41-88) and the median BMI was 23.4 kg/m2 (16.4-31.9). All pts were ER+ and 80% were PgR+. Most of pts had a baseline PS of 0 or 1, 90% had invasive ductal carcinoma, and 10% had invasive lobular carcinoma. Postoperative recurrence was detected in 84% and these pts had a median duration of adjuvant ET of 30.5 mo. (5.3-58.9). De novo stage IV ABC was present in 16%, with a median duration of first-line ET of 5 mo. (2.3-10.8). Adjuvant chemotherapy including anthracycline- and/or a taxane-containing regimen was administered in 58% (29/49). As adjuvant ET before initial recurrence, 34 pts received non-steroidal aromatase inhibitors (AIs) (88.0%), 1 received a steroidal AI (2.3%), and 3 received a selective estrogen receptor modulator (SERM). As first line ET in de novo stage IV, 7 pts (14%) were treated with AIs or a SERM (1 case). 2nd-line TPCs were also used, with 40 pts receiving fulvestrant (82%), 5 receiving SERMs (10%), 3 receiving a mTOR inhibitor plus a steroidal AI (6%), and one patient receiving an AI alone. The overall CBR was 44.9% (90% CI: 34.6-57.6, p=0.009), and CBR was similar across following subgroups (PgR+: n=39, 51.3%, 90% CI: 39.6-65.2, p=0.0016; very low sensitivity group: n=17, 58.8%, 90% CI: 42.0-78.8, p=0.003; non-visceral metastases: n=25, 40%, 90% CI: 34.1-65.9, p=0.0175). However, there were not statistically significant CBR in PgR- (n=10, 20.0%, 90% CI: 8.7-50.7, p=0.617), fulvestrant subgroup (n=40, 40.0 %, 90% CI: 29.2-54.2, p=0.063), low sensitive group (n=32, 37.5%, 90% CI: 26.0-53.6, p=0.1326), and visceral metastases (n=24, 48%, 90%CI; 28.2-60.3 p=0.072). The median PFS was 7.1 mo. (95% CI: 5.6-10.6). Conclusion: This study shows that 2nd line ETs was effective and might be a valid option in the sequence of treatments for postmenopausal women with ABC with low sensitivity to initial ET. It was suggested that PgR and visceral metastasis were significant predictive factors for CBR.
The outcome of lung metastasis treated with fulvestrant is superior to that of liver metastasis for metastatic breast cancer

Min He¹, Jun-Jie Li¹, Wen-Jia Zuo¹, Lei Ji¹, Xi-Chun Hu¹, Zhong-Hua Wang¹ and Zhi-Ming Shao¹. ¹Fudan University Shanghai Cancer Center, Shanghai, China.

Background: Endocrine therapy is the preferred option in patients presenting with hormone receptor (HR)-positive metastatic breast cancer (MBC). While visceral metastasis is a negative prognostic factor, few studies have distinguished between the prognosis of different visceral sites.

Patients and methods: 505 HR-positive MBC patients administered with fulvestrant at Fudan University Shanghai Cancer Center during a 6-year period were enrolled, 398 patients receiving fulvestrant 500mg were included in final analysis. Logistic regression models were used to identify prognostic factors associated with progression-free survival (PFS). Kaplan-Meier analysis was utilized to compare PFS of lung and liver metastases.

Results: Median follow-up time was 26 months. 233 patients presented with baseline visceral metastases, including 138 lung w/o liver metastases (lung metastasis without liver involvement), 51 liver w/o lung metastases (liver metastasis without lung involvement), and 41 with both lung and liver metastases. Median PFS was 6.8 months (5.6 months for visceral metastases, 9.2 months for non-visceral metastases, \( P = 0.028 \)). Lung w/o liver metastases had longer median PFS compared to liver w/o lung metastases or both lung and liver metastases (9.6 months, 3.7 months and 3.2 months, respectively, \( P < 0.001 \)). In addition, patients with liver metastases experienced a significantly worse PFS when compared with those without liver involvement (3.7 versus 9.2 months, \( P < 0.001 \)). In multivariate analyses, PFS benefits of fulvestrant were observed in patients with longer disease-free interval, absence of liver metastases, and no previous chemotherapy for MBC.

Abbreviations: PgR, progesterone receptor; UK, unknown; HR, hazard ratio; 95% CI, 95% confidence interval; ET, endocrine therapy; NE, not estimable. Lungw/o liver, lung metastasis without liver involvement. aMedian PFS in months. P < 0.05 was considered significant, significant values was presented in bold.

**Conclusion:** Patients with lungw/o liver metastases benefit as well as those with non-visceral metastases from fulvestrant. Visceral metastases should distinguish between liver or lung when treating HR-positive/HER2-negative MBC with endocrine therapy.
Introduction: There is continuing debate whether efficacy of ET is different in non-visceral metastases (nVM) than VM. Recently fulvestrant 500mg, has been reported to have greater efficacy than an aromatase inhibitor (AI), anastrozole, particularly in nVM – implying efficacy may be both site and agent dependent. Absence of significant overall survival (OS) difference in PALOMA 1 & 3 has increased interest in site of disease, especially given the OS advantage for fulvestrant 500mg monotherapy.

Patients & Methods: Individual patient level data was obtained from 7 randomised controlled trials (RCTs) involving SERM, AI & SERD used as 1st Line ET in known HR+ BC were used in this meta-analysis (MA). Five were Phase 3 double-blind, placebo controlled RCTs. Details of the studies, type of ET and patient numbers are shown in Table. All were rigorously assessed for clinical benefit rate (CBR), progression free survival (PFS), duration of clinical benefit (DoCB) and OS.: Details of the studies, types of ET and patient numbers are shown in the Table. A two stage MA IPD meta-analysis was used to analyse these outcomes CBR, PFS, OS & DoCB. Peto method for pooled odds ratios was used to calculate p values and CI for CBR, yYusef pPeto method was used to calculate p-values and CI for PFS, OS, and DoCB. Random effect for trial was included when Tarone’s test for heterogeneity was significant, otherwise fixed effect models were generated.

Results: Outcome data is present for each study and then summarised under SERM, AI, SERD and ‘all Ets combined’. Odds Ratios (Ors) & Hazard Ratios (HRs) for VM versus nVM by endocrine agent are shown in the Table.

</table>
Conclusions: This is the largest reported individual patient MA for nVM versus VM in patients with known HR+ advanced BC and clinical outcomes (CBR, DoCB, PFS & OS) approved to regulatory standards.

1) nVM had significantly better clinical outcomes compared to VM when treated by anti-estrogen receptor blocking agents (SERM & SERD) but not when treated by Ais, which have a fundamentally different mechanism of action.

2) SERD (Fulvestrant 500mg) significantly increased all four clinical outcomes. For nVM compared to VM, fulvestrant put more patients into CB, kept them in remission (DoCB) for longer, resulting in 44% reduction in disease progression and a 50% reduction in death.

3) Site of metastases (ie nVM or VM) is one of the factors to consider when selecting patients for endocrine mono or combination ET (plus CDK4/6i) in the 1st Line setting.
Estetrol for treatment of advanced ER+ breast cancer

Marcus Schmidt, Arnd Hönig, Carole Verhoeven, Katrin Almstedt, Marco Battista, Hans Georg Lenhard, Jan Krijgh and Herjan Coelingh Bennink. 1Klinik und Poliklinik für Geburtshilfe und Frauengesundheit, University of Mainz, Mainz, Germany; 2Geburtshilfe und Frauenheilkunde, Katholisches Klinikum Mainz, Mainz, Germany and 3Pantarhei Oncology BV, Zeist, Netherlands.

Introduction: Currently, a multi-center, open-label, phase I/IIA, dose-escalation study with the fetal estrogen estetrol (E4) is ongoing in Germany in postmenopausal patients with advanced breast cancer (ABCE4 study). The objective of the study is to assess safety and tolerability of different doses of E4 (range 20-60 mg per day). In addition initial anti-tumor response will be determined.

Study design: Patients are treated for 12 weeks with E4; 4 weeks in Phase I and thereafter 8 weeks in Phase IIA. Phase I of the study will follow the traditional 3 + 3 design to determine the optimal dose in patients with advanced breast cancer. Patients are treated in cohorts of three all receiving the same dose. Occurrence of dose limiting toxicity (DLT) at completion of phase I (4 weeks treatment) will determine escalation to the next higher dose in the study. After completion of Phase I, patients will continue treatment for 8 weeks to assess preliminary anti-tumor response in Phase IIA. Treatment may continue beyond 12 weeks based on evaluation of the patient and her treating physician.

Results: Phase I of the first treatment cohort with 20 mg E4 per day has been completed. A total of six postmenopausal women with advanced breast cancer has been included in the first cohort. One patient withdrew consent before treatment with E4 started. She was replaced. Two patients discontinued the study before completion of Phase I for reasons other than DLTs. These patients were unevaluable for toxicity and were also replaced. Three patients completed Phase I. One patient discontinued the study during Phase IIA due to disease progression after 9.5 weeks of E4 treatment. One patient completed both the Phase I and IIA part of the study. She had stable disease at study completion and wanted to continue E4 treatment because of improved well-being. Tumor assessment after 24 weeks of E4 treatment showed again stable disease. One patient is presently in Phase IIA of the study.

None of the patients experienced a DLT. The 20 mg E4 dose was well tolerated by all patients. In total 17 adverse events were reported. Adverse events were mainly of mild or moderate intensity. Five of 17 events fulfilled criteria of seriousness; none of these events were considered to be related to the E4 treatment. Four events were considered to be possibly related to the E4 treatment. These events were increased endometrial thickness, dry skin, pruritus and fatigue, all of mild intensity. A remarkable finding was that three of the five patients treated with E4 reported to the investigator to “feel better” than before the start of E4 treatment. This “feeling better” was described by one of the patients as: “feeling less down and exhausted; instead feeling much more optimistic, powerful and positive when taking E4”.

So far anti-tumor response could be estimated in one patient. This patient, who started the study with progressive disease, had stable disease as shown by tumor assessments after 12 weeks and 24 weeks of E4 treatment.

Conclusion: Based on these results, we conclude that a daily dose of 20 mg E4 is well tolerated. The majority of patients experienced favorable subjective effects on wellbeing. The data obtained with the 20 mg dose E4 allow dose escalation to the next higher dose of 40 mg E4 per day.
Meta-analyses of visceral versus non-visceral metastases treated by AI & SERD agents as 2nd line endocrine therapy (ET) for HR+ breast cancer (BC)

John Forsyth Russell Robertson\(^1\), Angelo Di Leo\(^2\), Stephen Johnston\(^3\), Stephen Chia\(^4\), Judith Bliss\(^5\), Ian Bradbury\(^6\) and Christine Campbell\(^6\). \(^{1}\)University of Nottingham, Nottingham, Nottinghamshire, United Kingdom; \(^{2}\)Sandra Pitigliani Medical Oncology Unit, Hospital of Prato, Prato, Italy; \(^{3}\)Royal Marsden NHS Foundation Trust, London, United Kingdom; \(^{4}\)British Columbia Cancer Agency, Vancouver, Canada; \(^{5}\)The Institute of Cancer Research, London, United Kingdom and \(^{6}\)Frontier Science, Kincraig, Inverness-shire, United Kingdom.

There is a prevailing belief that ET for HR+ advanced BC is not as effective in patients with visceral metastases (VM) compared to non-visceral metastases (nVM), particularly with later lines of ET. Recently fulvestrant 500mg (Ful 500), has been reported to have greater efficacy in nVM compared to i) VM treated by Ful 500 but also compared to ii) nVM treated by Ful 250 (2nd line) and iii) nVM treated by aromatase inhibitor (AI), anastrozole (1st Line) – implying both site and agent related efficacy. Absence of significant overall survival (OS) difference in PALOMA 3 (2nd line) has increased the debate regarding when to add CDK 4/6is to ET, especially given the OS advantage for Ful 500 monotherapy in the 1st & 2nd line settings.

**Patients & Methods:** Anonymised, individual patient level data was obtained from randomised controlled trials (RCTs) involving AI & SERD used as mono-therapy in 2nd or 3rd Line setting in known HR+ BC. All the trials were Phase 3 double-blind, placebo RCTs. All were rigorously assessed for clinical benefit (CB), progression free survival (PFS), duration of CB (DoCB) and OS. Details of the studies, types of ET and patient numbers are shown in the Table.

**Results:** Outcome data is presented for each study and then summarised under AI, SERD (Ful 250 or 500) and 'all Ets combined'. Odds ratios (Ors) & hazard ratios (HRs) for VM versus nVM by endocrine agents are shown in the Table.

[Pats=Patients; (n)=number; CBR-Clinical Benefit Rate; p-values pMedian PFS (months) for nVM for AI, SERD250, SERD500 & all Ets combined were 5.4, 5.5, 11.0 & 5.5 respectively; for VM they were 2.9, 3.5, 5.5 & 3.2 respectively.]
Median OS (months) for nVM for AI, SERD250, SERD500 & all Ets combined was 24.2, 26.0, 35.4 & 25.4 respectively; for VM the figures were 22.8, 20.8, 26.4 & 22.0 respectively. **Conclusions:**

1) In the 2nd line HR+ setting AI & Ful 250 both significantly increased PFS & OS in nVM versus VM. Longer PFS appears due to longer duration of control (DoCB) than increasing the number of patients responding (CBR).

2) Median OS for nVM ranged from 24–35 months versus 20.8-26.4 months for VM: for the majority of patients the 2nd line ET setting is not immediately life threatening and ET is therefore an option to consider.

3) These data on site of disease (nVM vs VM) contribute to the selection of which patients should receive endocrine mono- and which endocrine combination therapy (ie plus mTORi or CDK4/6i) in the second line setting.
"Real world" characteristics, treatment patterns and outcomes of patients with hormone receptor positive (HR+), human epidermal growth factor 2 negative (HER2-) metastatic breast cancer (MBC)

Chris Twelves1,2, Sue Cheeseman1, Matt Thompson1, Majid Riaz1, Timothy Perren1,2, Necibe Ahat-Donker1,3, Will Sopwith1,3, Melissa Myland3, Adam Lee4, Stuart Turner5 and Geoff Hall1,2. 1Leeds Cancer Centre, Leeds, United Kingdom; 2University of Leeds, Leeds, United Kingdom; 3IQVIA, London, United Kingdom; 4Novartis Pharmaceuticals UK Ltd, Surrey, United Kingdom and 5Novartis Pharmaceuticals Corporation, East Hanover.

OBJECTIVES: Outcomes for patients with MBC vary according to disease phenotype and treatment history. We present UK real-world patient characteristics, treatment patterns and outcomes for patients with HR+/HER2- BC treated at a single cancer center.

METHODS: A retrospective review of health records including coded data, unstructured text and clinical review of patients treated from January 2012 to March 2018 identified females ≥ 18 years with metastatic or locally advanced HR+/HER2- BC. Those enrolled in clinical trials, with operable local recurrence as only disease site, incomplete treatment records or significant secondary malignancy were excluded. Patient characteristics, systemic, local (radiotherapy/surgery) and supportive treatments, health care resource use (HRU) and overall survival (OS) are presented. OS was estimated using the Kaplan-Meier method, censoring patients alive at study end.

RESULTS: 253 patients meeting study inclusion criteria were identified (median age 67, IQR 56,76; 84% post-menopausal), of whom 47 (19%) had locally advanced disease (T4 and/or N3), 75 (30%) had MBC at initial presentation and 131 (52%) had metastatic disease at first recurrence. Among patients with MBC at initial presentation, all received systemic treatment following diagnosis, including chemotherapy (35%), endocrine (93%) and targeted therapy (i.e. everolimus 7%). Among those recurring with MBC, 97% subsequently received systemic treatment, including chemotherapy (50%), endocrine (93%) and targeted therapy (27%). For patients recurring with MBC, the most common first line therapies (LoT) were letrozole (20%), exemestane (single agent, 15%), anastrozole (14%), everolimus (with exemestane, 11%) and paclitaxel (9%). For patients diagnosed with MBC, the most common first LoT were letrozole (47%), anastrozole (23%) and EC (11%). At second LoT, the most commonly used regimen for patients recurring with MBC was fulvestrant (13%) and for patients with MBC at initial diagnosis, it was exemestane (19%). Median OS for patients recurring with MBC was estimated to be 2.11 years (IQR 1.80,3.05), compared with 2.65 years (IQR 2.24,2.95) for those with metastatic disease at initial diagnosis. Median available follow-up time for the whole cohort was 2.85 years (IQR 1.42,4.82).

CONCLUSIONS: Patients with overt metastatic disease at presentation comprise a substantial proportion of those treated for MBC. With the follow-up time available, estimated median OS for patients with metastatic disease at initial presentation appears somewhat better than for those recurring with metastatic disease. Real world analysis demonstrates diverse treatment pathways for patients with HR+, HER2- MBC, reflecting the individualized care they receive.
Estrogen levels in premenopausal patients (pts) with hormone-receptor positive (HR+) early breast cancer (BC) receiving adjuvant triptorelin (Trip) plus exemestane (E) or tamoxifen (T) in the SOFT trial: SOFT-EST substudy final analysis

Meritxell Bellet1, Kathryn Gray1, Prudence Francis1, Istvan Láng1, Eva Ciruelos1, Ana Lluch1, Miguel Ángel Climent1, Gustavo Catalán1, Antoni Avella1, Uriel Bohn1, Antonio González-Martin1, Khalil Zaman1, Roser Ferrer1, Analía Azaro1, Agnita Rajasekaran1, Lorena De la Peña1, Gini Fleming1 and Meredith M Regan1. 1SOFT-EST Investigators, SOLTI, and International Breast Cancer Study Group, Bern, Switzerland.

**Background:** Optimal endocrine therapy for premenopausal pts with early HR+ BC may depend on complete estrogen suppression with GnRH analog, which is crucial when using concurrent aromatase inhibitors (AIs). SOFT-EST is a prospective substudy of the phase 3 SOFT trial aiming to describe estradiol (E2), estrone (E1) and estrone sulphate (E1S) during the first 4 years (y) of monthly Trip+E/T and to assess if there were suboptimally estrogen suppressed (SES) pts in the E+Trip group. Secondary objectives included associations of baseline (BL) factors with SES, early SES with later SES, and SES with disease-free survival (DFS; exploratory objective).

**Methods:** Patients from select centers who consented and enrolled in SOFT, selected Trip as ovarian function suppression method, and were randomized to E+Trip or T+Trip were eligible for SOFT-EST until the accrual goal (120 pts: 90 E+Trip; 30 T+Trip). Prem status for SOFT eligibility was based on local E2. Blood sampling timepoints were 0, 3, 6, 12, 18, 24, 36 & 48 months (m) until Trip stopped. Serum estrogens were measured centrally by high specificity/sensitivity GC/MSMS and were not available during the study. For 4y analyses, SES was defined as E2 levels >2.72 pg/mL in ≥2 post-BL samples (E2 levels *not consistent with postmenopausal (PM) status on AIs* [Smith IE, JCO 2006]), or vaginal bleeding >3m after Trip start, or pregnancy. We explored 2 additional cutoffs: >10 pg/mL (*clearly inconsistent with PM status on AIs*) and >20 pg/mL (*inconsistent with GnRH analog-related PM status*). The analysis is intention-to-treat based on E/T assignment; as-treated analyses are forthcoming.

**Results:** From Mar 2009 to Jan 2011, 109 pts (E/T=83/26) started Trip and had ≥2 samples drawn. In pts assigned E+Trip, median reductions from BL in E1, E2 and E1S were >95% at all timepoints and significantly lower than in T+Trip. Post-BL E2 geometric mean ranged 0.8-1.3 pg/mL in E+Trip and 16.5-18.3 pg/mL in T+Trip. 21 (25%), 11 (13%) and 6 (7%) pts assigned to E+Trip had E2>2.72, >10, and >20 pg/mL in ≥2 post BL samples or vaginal bleeding (n=3), respectively. Early SES [(≥1 E2 value >2.72 pg/mL or vaginal bleeding in the firsty] predicted later SES [≥1 E2 value >2.72 or vaginal bleeding thereafter (n=1); p<0.001]. BL factors related to SES were higher E2, lower FSH and lower LH values (p=0.02, p<0.01, p<0.01 respectively). 12m FSH levels were not related to SES. In pts assigned E+Trip, after 6y median follow-up, DFS events were seen in 0 of 21 pts with SES vs 5 of 62 pts without SES.

**Conclusions:** Most pts on E+Trip had a profound E2 drop consistent with postmenopausal status on AI, but >20% assigned to E+Trip had ≥2 E2 values >2.72 pg/mL and 4% had vaginal bleeding, with those having higher E2, lower FSH/LH at BL being at higher risk. SES at 12m predicted subsequent SES. Few DFS events limit the ability to assess clinical relevance of SES with disease outcomes.

Analysis of DRFI and OS of HR-positive, HER2-negative breast cancer patients treated on the BIG1-98 study, classified according to a novel, integrated, clinical-pathologic and genomic classification method

David Demanse, Stephen J Luen, Dominique Pinet, Meredith Regan, Rosita Kammler, Beat Thuerlimann, Giuseppe Viale, Marco A Colleoni, Sherene Loi and Wolfgang Hackl. ¹Novartis Pharma AG, Basel, Switzerland.

Background and Objectives
HR\textsuperscript{pos}, HER2\textsuperscript{neg} early breast cancer is molecularly heterogeneous. Classifications that integrate genetic, genomic and clinical-pathologic data (nodal status, tumour size, tumour differentiation, Ki-67 status, PR expression) are lacking. In a previous study we have defined three different molecular groups of invasive ductal luminal breast cancer (IDLBC) using clinical prognostic variables, gene expression, copy number variation and mutation data from the METABRIC series [1, 2] and showed that IDLBC groups (IDLBC1, -2, -3) had distinct prognostic outcomes [3, 4]. The 3 groups differ by DNA damage load, predominant lesion type, characteristic lesion patterns, oncogenic driver mechanisms and time to first recurrence. Here we evaluated the prognostic and predictive value of these groups on patients treated on the BIG1-98 study.

Methods
We used our predefined subgroups (IDLBC1, -2, -3) to classify patients in the BIG1-98 set [5, 6]. A weighted Cox proportional hazards regression model was used to assess the association between IDLBC subtype, treatment on OS and DRFI endpoints in the BIG1-98 study. Weighted chi-squared tests were used for categorical variables and weighted t-tests for mutational burden. All statistical computations were carried out in R v.3.2.3.

Results
Five hundred thirty eight breast cancers (ductal 75%, lobular 17%, 8% other) were included in this study. The DNA damage burden of IDLBC1 or -2 type tumours was significantly lower compared to IDLBC3 (mean lesion numbers: 9, 11, 18.5). IDLBC1 type tumours (48%) harboured mainly oncogenic point mutations (predominantly PIK3CA 51%, MAP3K1 27%, NCOR1 22%, FANCD2 20%). IDLBC2 (34%) and IDLBC3 type tumours (18%) were both mutated (PIK3CA 53% vs 38%, GATA3 12% vs 30%, TP53 10% vs 37%, CDH1 20% vs 8%), 8p11-12 (IDLBC3 38% vs IDLBC2 21% or IDLBC1 5%, p value < 0.001) and/or 11q13-14 amplified (IDLBC3 46% vs IDLBC2 28% or IDLBC1 2%, p value < 0.001). Consistent with the higher DNA damage load patients with IDLBC3 type tumours had significantly shorter distant recurrence free intervals (DRFI) (HR (95% CI) 2.35 [1.99; 2.78] p-value= <2e-16) and significantly shorter OS compared to IDLBC1 or -2 (HR (95% CI) 2.55 [2.2; 2.96] p-value= <2e-16). Patients with IDLBC1 or -2 type tumours seemed to have the same survival regardless of hormonal treatment assignment. However, the IDLBC3 group derived greater magnitude of benefit from Letrozole compared to Tamoxifen (HR (95% CI): DRFI 0.85 [0.66; 1.09] vs. 0.53 [0.35; 0.79] interaction p-value=0.03, OS 0.98 [0.8; 1.21] vs 0.34 [0.25; 0.47], interaction p-value=2.5e-09).

Conclusions
We have validated our integrated clinical-pathologic and genomic classification method on an independent dataset of HR\textsuperscript{pos}, HER2\textsuperscript{neg} early stage breast cancer. Our classification also suggests differing magnitude of benefit for adjuvant Letrozole benefit. Prospective clinical studies will be required to validate and corroborate this novel classification approach.

Influence of competing risks of death on the interpretation of adjuvant endocrine therapy trials for breast cancer

Josee-Lyne Ethier¹, Wendy Parulekar², Lois Shepherd², Lily Summers², Kathrin Strasser-Weippl³, Dongsheng Tu² and Eitan Amir⁴. ¹Cancer Centre of Southeastern Ontario, Kingston, ON, Canada; ²Canadian Cancer Trials Group, Kingston, ON, Canada; ³Center for Oncology, Hematology and Palliative Care, Wilhelminen Hospital, Vienna, Austria and ⁴Princess Margaret Cancer Centre, Toronto, ON, Canada.

Background: Early stage, hormone sensitive breast cancer is associated generally with a good prognosis, with only a minority of patients expected to die of breast cancer. Death from causes other than breast cancer can dilute the patients at risk of breast cancer events and result in over-estimation of risk of recurrence and consequently the benefit from breast cancer therapy, a so-called immortal time bias. The MA.17R trial (Goss et al 2016) evaluated the role of extending adjuvant treatment with letrozole from 5 to 10 years. Here we determine the effect of analyzing the MA.17R trial using methods accounting for competing risks.

Methods: We compared conventional and competing risk methods for disease-free survival (DFS) and for distant recurrence-free survival (DRFS). In Kaplan-Meier analyses death from any cause was considered an event while cumulative incidence functions (CIFs) assumed death without recurrence to be a competing risk. The complement of the survival function (one minus the survival function) was used to estimate incidence of the primary event of interest. This was compared to estimates obtained using CIFs accounting for the occurrence of competing events.

Results: Non-breast cancer death was the most common event defining DFS and DRFS. Over the course of follow-up, there was increasing discrepancy between the risk of disease recurrence measured using Kaplan-Meier and CIF. Among letrozole treated patients the estimated distant recurrence at 5 years of follow-up was 5.4% using CIF and 9.6% using Kaplan-Meier. At 10 years of follow-up, the estimated distant recurrence was 8.4% using CIF and 20.0% using Kaplan-Meier. Similar results were observed for the placebo group (8.5% vs 12.1% at 5 years and 14.8% vs 27.3% at 10 years), and in patients with baseline cardiovascular disease (see Table). Benefit from letrozole on DFS and DRFS was greater when accounting for competing risk (hazard ratio [HR] for DFS 0.66, 95%CI 0.48-0.90; DRFS HR 0.75, 0.50-1.14) compared to the conventional method (DFS HR 0.79, 0.62-0.99; DRFS HR 0.91, 0.70-1.18). In women with baseline cardiovascular risk, the benefits of extended adjuvant letrozole when considering competing risk (DFS HR 0.38, 0.16-0.89; DRFS HR 0.46, 0.16-1.35) were also greater than those observed in the conventional analysis (DFS HR 0.55, 0.32-0.93; DRFS HR 0.59, 0.33-1.04). Treatment with extended letrozole did not influence non-breast cancer death in women who died with disease recurrence (HR 1.06, 0.74 -1.50) or in those with competing risk or censored from the analysis (HR 1.05, 0.73 -1.49).

Conclusion: Over the course of follow-up, estimates of DFS and DRFS differ increasingly if measured using Kaplan-Meier or CIF, with CIF estimates of risk being substantially lower. Using a competing risk model, the reduction in distant recurrence at 8 years with extended letrozole is less than 1%. Additional competing risk analyses of the MA.17 (Goss 2006) and MA.27 (Goss 2013) trials are ongoing.

Cumulative incidence of disease recurrence in patients with baseline cardiovascular risk

BACKGROUND
Assessment of restoration of ovarian function after chemotherapy is critical with respect to the initiation of different types of endocrine treatment in young high risk breast cancer patients

METHODS
In total, 1289 women who remained premenopausal or resumed premenopausal status after chemotherapy were randomized to receive 5 years of tamoxifen or 5 years of tamoxifen plus 2 years of ovarian suppression. The patients who did not resume menstruation were followed up for 2 years with tamoxifen treatment after finishing chemotherapy. Prospectively collected consecutive post-chemotherapy hormone and menstruation data were available for 705 breast cancer patients who enrolled tamoxifen-only treatment group or did not resume menstruation during follow up. This analysis evaluated the proportion of patients with pre-menopausal FSH levels (<30 mIU/ml), E2 levels (>40 pg/ml), and menstruation at any time point during treatment with tamoxifen.

RESULTS
During 5 years of tamoxifen treatment after chemotherapy for premenopausal breast cancer patients, 62% of patients resumed menstruation. Menstruation returned in 92% of patients under 35 years old but only in 31% of patients over 45 years old. Ovarian function, defined by serum FSH and E2 levels, resumed in 94% and 65% of patients, respectively, over 5 years. Most patients achieved ovarian function restoration during the first 2 years after chemotherapy, with 47.1% resuming menstruation and 86.2% and 50.3% achieving pre-menopausal FSH and E2 levels, respectively, in the first 2 years. Clinical factors related to menstruation restoration were younger age (HR = 6.38, 95% CI 1.33-3.47), 6 month hormone profile after chemotherapy (FSH<30: HR=1.67, 95% CI 1.28-2.17; E2 >40: HR=2.96, 95% CI 2.25-3.89), and anthracycline without taxane chemotherapy (HR=1.63, 95% CI 1.25-2.13).

CONCLUSIONS
During 5 years of tamoxifen treatment after chemotherapy, half of patients experienced menstruation restoration, including most very young patients under 35 years. The majority of patients experienced menstruation restoration in the first 2 years of tamoxifen treatment.
Confirmation of the TAILORx 21-gene expression trial using a real world observational database

Stanley E Waintraub, Claudine Isaacs, Andrew D Norden, Deena A Graham, Donna M McNamara, Suzanne C O'Neill, Ashwin Lakshmanan, Tommy Wu, Allison Maresca, Andrew L Pecora, Andre H Goy and Stuart L Goldberg.

1 John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, NJ; 2 Georgetown Lombardi Comprehensive Cancer Center, Washington, DC and 3 Cota Inc, New York, NY.

Background: The TAILORx study (NCT00310180) (TRx) has demonstrated the efficacy of endocrine therapy alone in early stage, lymph node negative, hormone receptor positive, her2neu oncogene negative breast cancer harboring an intermediate recurrence score (RS) on a 21-gene profile (OncotypeDx), obviating the need for adjuvant chemotherapy in a large subset of women. The study randomized and followed 6711 patients (pts) and required 9 years to reach its conclusion endpoints. The availability of the electronic health record (EHR) permits automated reviews, facilitating more rapid “real world” hypothesis testing (but not a replacement for randomized clinical trials), especially when there are clear variations in common practice patterns. However physician bias in treatment selection needs to be considered.

Methods: A retrospective review of the Cota Observational Cancer database, drawn from EHRs, of female pts with breast cancer who were 18 to 75 years of age; had hormone-receptor–positive, human epidermal growth factor receptor 2 (HER2)–negative, axillary node–negative breast cancer harboring an OncotypeDx RS 11-25 receiving adjuvant therapy following surgical resection of a 11-50 mm primary tumor (similar to TRx eligibility).

Results: 1009 pts from 23 cancer centers (107 oncologists) were identified, 850 (84.2%) received adjuvant endocrine therapy alone (E) and 159 (15.8%) received adjuvant chemoendocrine therapy (CE) as part of standard care (no randomization). 285 pts were age <50 yrs (E: 218, CE: 67) and 601 pts has RS 16-25 (E: 453, CE: 148). Treatment selection was imbalanced with oncologists more likely to utilize CE in younger pts (median age E: 59 yrs, CE: 53 yrs; p<0.01), larger tumors (median tumor size E: 16mm, CE: 20mm; p<0.001) and higher RS (median RS E: 16, CE: 21; p<0.001). With a median follow-up for survival since diagnosis of 3.7 years, the Kaplan-Meier estimated 5 yr overall survival rates were 98.9% with E and 97.8% with CE (p=0.23); the corresponding 5-yr OS in TRx were E: 98% and C: 98.1%. With a median 1.7 years follow-up for recurrence, 19 pts have suffered a disease distant or local recurrence (E: 13; CE: 6) yielding a 5-year recurrence-free survival of E: 95.2% and CE: 91% (p=0.05); the corresponding TRx result was E: 96.9% and CE: 97%. The 5-yr invasive disease-free survival (IDFS = death, local/distant, second primary) with 32 events was E: 92.7% and CE: 81.9% (p= 0.05); corresponding TRx E: 92.8 % and CE: 93.1%. Given the imbalance in treatment allocations, a multivariate analysis was performed, with older age (<0.001), CE choice (<0.006) and larger tumor size (p<0.05) remaining significant, but not increased RS (p=0.16) for 5-year IDFS. Among women age ≤50 with RS 16-25 (E: 118; CE: 60) the 5-yr IDFS was E: 95% and CE: 94%; the corresponding RS 16-20 TRx E: 92% and CE: 94.7% and RS 21-25 E: 86.3% and CE: 92.1%.

Conclusions: Using a real world data source, endocrine therapy alone appears to yield excellent 5-yr survival rates among pts with 21-gene RS 11-25 similar to the TAILORx trial. Treatment selection bias (with perceived higher risk pts allocated to CE) and shorter median follow-up limits full confirmation by this dataset.
A study of adverse vascular effects of adjuvant therapy with aromatase inhibitors in women with breast cancer

Henrik Lindman¹, Lina Dahlberg¹, Marita Larsson² and Tord Naessén². ¹Uppsala University, Uppsala, Sweden and ²Uppsala University, Uppsala, Sweden.

Background: There is a debate concerning risk of cardiovascular disease (CVD) from adjuvant therapy with aromatase inhibitors (AI). Randomized trials have indicated higher CV risk and one observational study higher risk of myocardial infarction, whereas other studies have pointed out no elevated risk. The first morphological sign of developing atherosclerosis is a thickening of the arterial intima layer, whereas in the longer perspective the media layer gets thinner - a process not captured when using conventional Carotid intima-media-thickness (CIMT). We therefore used high resolution ultrasound (HRU), to separately estimated the intima and media layers and calculate the I/M thickness ratio. A thicker intima and higher I/M thickness ratio are signs of adverse vascular effects. This principle of estimating vascular aging can strongly distinguish 70-yr old subjects with and w/o prevalent CVD, yielding C-values up to 0.90 in ROC-analysis.

Patients and Methods: We included 150 postmenopausal breast cancer women of whom 50 were treated with AI during at least 3 years, 50 with at least 3 years of tamoxifen and 50 were without endocrine therapy. Patients were investigated with non-invasive HRU (22MHz) of the common carotid artery (CCA). Non-parametric statistical methods were used, including Bootstrap quantile regression to obtain 95% confidence intervals (CI) and adjustment for potential confounders: age, smoking, use of statins, HbA1c and previous HRT.

Results: Of 150 included women, 132 remained having a technically acceptable ultra sound scans and no AI therapy before tamoxifen therapy; AI (#48); tamoxifen (#40) and no anti-hormone therapy (#44). Corresponding median ages were 66, 65 and 65 yrs and median treatment durations were 54 (AI) and 58 (tamoxifen) months.

AI therapy, compared to tamoxifen, showed a significantly thicker CCA-intima layer, p = 0.031. However, mean values of both CCA-intima thickness and I/M thickness ratio were very similar in the tamoxifen and the no anti-estrogen group; Thus, AI compared to the other two groups combined, had a significantly thicker intima layer (p = 0.009) and higher I/M ratio (p = 0.047), both indicating adverse vascular effects from AI therapy. After adjustment for potential confounders, AI therapy still showed a thicker CCA intima layer of 0.015 mm (95% CI .003, .027); p = 0.016.

In contrast, corresponding analysis using conventional Carotid intima-media thickness (CIMT), revealed no significant group differences or association to AI treatment duration.

Conclusion: More than three years of adjuvant therapy with aromatase inhibitors, compared to women having no anti-estrogen therapy or tamoxifen, was associated with signs of adverse vascular effects; thicker intima layer and higher intima/media ratio of the common carotid artery. After adjustment, the thicker intima layer remained significant. These findings are in accordance with reports of increased risk of cardiovascular events following adjuvant therapy with aromatase inhibitors.
Neoadjuvant exemestane or exemestane plus docetaxel and cyclophosphamide tailored by clinicopathological response to 8–12 weeks' exemestane exposure for ER+/HER2– postmenopausal breast cancer patients

Hiroyuki Yasojima¹, Nobuaki Sato², Norikazu Masuda¹, Takashi Morimoto³, Takayuki Ueno⁴, Chizuko Kanbayashi⁵, Koji Kaneko², Shigehira Saji⁶, Hironobu Sasano⁶, Satoshi Morita⁷, Shinji Ohno⁸ and Masakazu Toi⁹. ¹National Hospital Organization Osaka National Hospital, Osaka, Japan; ²Niigata Cancer Center, Niigata, Japan; ³Yao Municipal Hospital, Osaka, Japan; ⁴Breast Oncology Center, Cancer Institute Hospital, Tokyo, Japan; ⁵Fukushima Medical University, Fukushima, Japan; ⁶Tohoku University, Miyagi, Japan; ⁷Kyoto University Graduate School of Medicine, Kyoto, Japan and ⁹Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Aim To investigate the efficacy and safety of initial neoadjuvant endocrine therapy with exemestane (EXE) alone followed by tailored treatment: continued EXE monotherapy for responders or EXE plus docetaxel–cyclophosphamide (TC) combination therapy for non-responders.

Methods This open-label phase II study enrolled postmenopausal patients with primary invasive estrogen receptor (ER)-positive, HER2-negative, stage I–IIIA (T1c–T3 N0–2 M0) breast cancer and Ki67 index ≤30%. Patients first received EXE 25 mg/day for 12 weeks. Based on clinical response and change in Ki67 index, responders were defined as patients who achieved complete response (CR), partial response (PR) with Ki67 index ≤5% after treatment, or stable disease (SD) with Ki67 index ≤5% both before and after treatment. Non-responders were defined as patients with PR and Ki67 index >5% after treatment, or SD and Ki67 index >5% before or after treatment. For the subsequent 12 weeks, responders continued EXE monotherapy (continued EXE group) and non-responders received EXE plus 4 cycles of TC (docetaxel 75 mg/m² and cyclophosphamide 600 mg/m² every 3 weeks) (EXE+TC group). Primary endpoint was clinical response (CR and PR) at week 24.

Results A total of 58 patients (median age 60 years, range 53–67 years) were enrolled between December 2010 and May 2016. Five patients discontinued treatment in the initial 12-week EXE monotherapy period; therefore 53 received the subsequent treatment. After 8–12 weeks of initial EXE monotherapy, 15 patients were classified as responders (8 with PR and Ki67 index ≤5% after treatment, 7 with SD and Ki67 index ≤5% before and after treatment) and 38 as non-responders (5 with PR and Ki67 index >5% after treatment, 33 with SD and Ki67 index >5% before or after treatment). Clinical response rates at weeks 12 and 24 were 71% (10/14, 95%CI 41.9–91.6%) and 57% (8/14, 95%CI 28.9–82.3%), respectively, in the continued EXE group, and 16% (4/25, 95%CI 4.5–36.1%) and 56% (14/25, 95%CI 34.9–75.6%), respectively, in the EXE+TC group. At week 24, no significant difference was found in median Ki67 index between the continued EXE and EXE+TC groups (1.4% and 2.0%, respectively). The proportion of patients with preoperative endocrine prognostic index (PEPI) 0 was higher in the continued EXE than in the EXE+TC group (60% vs 29%), but not significantly so (P=0.058, Fisher's exact test).

The breast-conserving surgery rate was 93% and 56% (continued EXE and EXE+TC groups, respectively). Adverse events (AEs) ≥grade 3 were reported in 40% (21/53) of patients (continued EXE group 8%, 1/15; EXE+TC group 53%, 20/38). The most common AEs were leukopenia (37%, 14/38), neutropenia (32%, 12/38), and febrile neutropenia (16%, 6/38) during chemotherapy (EXE+TC group).

Conclusion Tailored treatment maintained the favorable clinical response to EXE alone in responders and improved subsequent clinical response in non-responders. EXE+TC was associated with higher incidence of hematological AEs, but these were manageable. The results show the effectiveness of tailored neoadjuvant endocrine and chemoendocrine therapy in postmenopausal ER-positive breast cancer patients. (JBCRG-11TC; UMIN000004752)
Serum concentrations of tamoxifen and Z-endoxifen may predict sexual dysfunction in the 2nd year of adjuvant endocrine treatment

Thomas Helland1,2, Martha E Haugstøyl1,2, Kari Britt Hagen1, Jan T Kvaløy4, Siri Lunde3, Kirsten Lode3,4, Ragna A Lind1,2, Birgitta H Gripsrud3,4, Ersilia Bifulco2, Nebeyaet S Gebreslase2, Janne Jonassen9, Steinar S Hustad2, Turid Aas1, Tone H Lende3, Ernst A Lien1,2, Emiel AM Janssen3,4, Gunnar Mellgren1,2 and Håvard Søiland. 1Haukeland University Hospital, Bergen, Norway; 2University of Bergen, Bergen, Norway; 3University of Bergen, Bergen, Norway and 4University of Stavanger, Stavanger, Norway.

Background and rationale: Side effects of adjuvant treatment with tamoxifen (tam) may impair Quality of Life (QoL) and have been suggested as an independent variable for discontinuation of tam1. There are large inter-patient variabilities in prevalence and severance of side effects among tam users. Therefore, there is a need for biological markers that can predict side effects. A potential biological predictor is the serum concentrations of tam and/or its metabolites. In this prospective observational study we have analyzed serum concentrations of tam and 9 metabolites over 3 years. Patients Reported Outcome Measures (PROM) were obtained to elucidate possible associations between side effects, adherence and tam metabolism.

Methods: Breast cancer patients using adjuvant tam (20mg/d) were recruited through the Prospective Breast Cancer Biobank project between 2011 and 2016. Inclusion criteria were ER positive status, ≥ 6 months tam use, tumor size of ≥0.1 cm and being able to read and write Norwegian. Concentration levels of tam and metabolites in serum were analyzed by LC-MS/MS2 and adherence data were collected through the Norwegian prescription database. PROM-data comprised of validated questioners reporting side effects of endocrine treatment and QoL. Statistical analyses comprised non-parametric tests, logistic regression, chi square tests and the Benjamin-Hochberg procedure to correct for multiple testing.

Results: Associations between metabolite concentrations and side effects were run as a cross sectional analysis (N=149) and separate analysis of each year of follow-up with 85, 77 and 65 patients at the 1st, 2nd and 3rd year respectively. We found that 78 % of patients reported side effects, 66 % reported mood swings, 21 % reported severe hot flushes and 71 % reported decreased libido. When analyzing years separately, we found that on the 2nd year patients experiencing vaginal dryness had significantly higher levels of tamoxifen (P=0.032, after correction for multiple testing and adjustment for clinical relevant variables) compared to patients not experiencing vaginal dryness. Also, on year 2 the patients in the lower quartile of Z-endoxifen (≤ 17.9 nM) had significantly lower libido (p=0.015) compared to patients with Z-endoxifen levels >17.9 nM after adjustment for clinical relevant variables and correction for multiple testing. Analyses regarding adherence are not complete and more results will be presented in the poster.

Discussion: Our data indicates that high serum concentrations of tam and low concentrations of Z-endoxifen are associated with vaginal dryness and sexual dysfunction. Patients reporting “very low libido” had the highest levels of tam, suggesting that slow metabolic conversion and accumulation of tam may contribute to sexual dysfunction. Our results were only significant in the second year of follow-up, possibly because patients wait to resume sexual activity after diagnosis, chemo and surgery. After receiving advice (i.e. lubricants), the symptoms are often reduced in the subsequent follow-up (3rd year). In conclusion, our results indicate that monitoring tam serum concentrations may be used to predict side effects.

A nationwide data on the cardiovascular protective effect of tamoxifen and aromatase inhibitor in postmenopausal women with breast cancer

Hyeong-Gon Moon¹, Sung Hyouk Choi¹, Yujin Park¹, Ji Gwang Jung¹, Young Wook Ju¹, Kyoung Eun Kim¹, Yumi Kim¹, Eunshin Lee¹, Han-Byoel Lee¹, Wonshik Han¹, Dong-Young Noh¹ and Hyung-Jin Yoon¹. ¹Seoul National University College of Medicine, Seoul, Republic of Korea.

A large proportion of breast cancer patients receive hormonal therapy as their adjuvant treatment options. For postmenopausal women, the initial choice for the hormonal therapy is aromatase inhibitor (AI), and tamoxifen (TM) is reserved for women experiencing severe side effects against AI or having low bone density. An important but unresolved clinical question regarding the use of AI in postmenopausal women is the safety of AI regarding the risk cardiovascular events. Studies have shown inconsistent results over the cardiovascular safety of AI and TM. In this study, we investigated the risk of developing cardiovascular and cerebrovascular events in women with breast cancer who receive hormonal therapy using AI, TM, or both. To this end, we used the National Health Insurance Sharing Service in Korea which is provided by National Health Insurance Service. The database provides anonymized insurance data for research purposes after the approval of the review committee. In the database, we identified 47,569 women with the age older than 55 who were diagnosed with breast cancer. Patients were classified as no hormonal treatment group (n=18,807), AI group (n=19,584), TM group (n=7,081), or Switch group (n=2,097). The Switch group was defined as the women with history of both AI and TM prescriptions. During the studied period, a total of 2,032 cardiovascular or cerebrovascular events (CVE) were recorded.

Overall, the women prescribed with TM had significantly less hazard ratio for developing CVE when compared to the women who did not receive any hormonal treatment (HR 0.809 95% C.I. 0.706-0.928). However, this protective effect of tamoxifen was not observed in either AI or Switch group (HR 0.917 95% C.I. 0.833-1.010, and HR 0.856 95% C.I. 0.695-1.053, respectively). The protective effect of TM was also similar in women older than 60 (HR 0.808 95% C.I. 0.696-0.938). The cardiovascular and cerebrovascular protective effects of tamoxifen was also substantial in high risk women defined by their family history of cardiovascular diseases and the diagnosis of hypertension or diabetes.

Our results suggest that the use of TM is associated with a substantial protective effect against developing cardiovascular or cerebrovascular events in women with breast cancer. However, the protective effect was not observed for women receiving AI. Our data suggest the potential tailored approach in hormonal treatment in breast cancer patients who are at high risk of cardiovascular of cerebrovascular events.
No impact of osteoporosis or bisphosphonate use for osteoporosis on breast cancer outcome: A sub-study of the DATA trial

Irene E van Hellemond1, Carolien H Smorenburg2, Petronella G Peer3, Astrid C Swinkels4, Caroline M Seynaeve5, Maurice J van der Sangen6, Judith R Kroep7, Hiltje de Graaf8, Aafke H Honkoop9, Frans L Erdkamp10, Francette W van den Berkmortel11, Wilfred K de Roos12, Sabine C Linn13, Alexander L Imholz14, Maaike de Boer1 and Vivianne C Tjan-Heijnen1. 1Maastricht University Medical Center, Maastricht, Netherlands; 2Medical Center Alkmaar, Alkmaar, Netherlands; 3Radboud University Medical Center, Nijmegen, Netherlands; 4Netherlands Comprehensive Cancer Organisation (IKNL), Nijmegen, Netherlands; 5Erasmus MC Cancer Institute, Rotterdam, Netherlands; 6Catharina Hospital, Eindhoven, Netherlands; 7Leiden University Medical Centre, Leiden, Netherlands; 8Medical Centre Leeuwarden, Leeuwarden, Netherlands; 9Isala Clinics, Zwolle, Netherlands; 10Zuyderland Medical Center, Sittard-Geleen, Netherlands; 11Zuyderland Medical Center, Heerlen, Netherlands; 12Gelderse Vallei Hospital, Ede, Netherlands; 13Netherlands Cancer Institute, Amsterdam, Netherlands and 14Deventer Hospital, Deventer, Netherlands.

Background:
The phase III DATA study (NCT00301457) investigates the efficacy of 6 versus 3 years of adjuvant anastrozole after an initial 2-3 year treatment with tamoxifen in postmenopausal women with breast cancer. A reduced bone mineral density (BMD) is associated with a lower risk of breast cancer. Bisphosphonates as adjuvant therapy in postmenopausal patients have been shown to prevent (distant) breast cancer recurrences. In this planned side-study of the DATA trial we assessed the relationship between osteoporosis and distant recurrence free survival (DRFS), and evaluated the effect of bisphosphonate use for reduced BMD in general on DRFS.

Methods:
Decisions on BMD measurements and bisphosphonate use in the DATA study were left to the treating physician. We registered all BMD measurements and start of bisphosphonate-use. BMD was measured by a dual-energy x-ray absorptiometry (DEXA) scan of the lumbar spine/hip. We used a landmark of 3 years beyond the start of anastrozole, to create 3 different groups by BMD values based on DEXA scans made before the landmark and before a DRFS event (normal T score >-1.0, osteopenia T score <-1.0, osteoporosis T score <-2.5). Kaplan Meier methodology was used for analyzing the DRFS for these groups. The events ending a period of DRFS were defined according to the STEEP criteria. For analyzing the relationship between bisphosphonate use and DRFS, overall bisphosphonate use was integrated as a time dependent covariate.

Results:
Of the 1860 DATA patients, 1142 (65.5% in the 6-year arm and 62.9% in the 3-year arm) had a DEXA scan within the first 3 years after randomization. A normal BMD was diagnosed in 436 (38.2%) patients, osteopenia in 565 (49.5%), and osteoporosis in 141 (12.3%). Of the latter group, 112 (80.9%) used bisphosphonates. In the total study population (n=1860), bisphosphonates were overall used over time before a DRFS event in 226 patients (24.2%) in the 6-year arm and 201 patients (21.7%) in the 3-year arm. During the study, only 46 patients used bisphosphonates without a diagnosis of osteopenia/osteoporosis.

After a median follow up of 5.0 years from the landmark (interquartile range 4.3-5.7), osteoporosis (n=141) did not have a significant impact on DRFS when compared with the group without osteoporosis (normal/osteopenia (n=1001)) (HR 1.19, p=0.24 in the 6-year arm and HR=0.79, P=0.56 in the 3-year arm, P interaction=0.45). Neither when compared with only the group with a normal BMD (n=436) (HR=1.15, p=0.72 in the 6-year arm and HR=0.67, p=0.34 in the 3-year arm, P interaction=0.35).

Within the group with osteoporosis, bisphosphonate use did not lead to a better DRFS (HR=1.47, P=0.72 in the 6-year arm and HR 0.65, P=0.61 in the 3-year arm, P interaction=0.55). Bisphosphonate use in general was also not associated with DRFS (HR 1.31, P=0.13 in the 6-year arm and HR 0.88, P=0.52 in the 3-year arm, P interaction=0.14).

Conclusion:
In this DATA sub-study, we observed no association between the presence of osteoporosis before the landmark of 3 years after the start of anastrozole and DRFS. However, as most patients with early osteoporosis also were treated with bisphosphonates this may have influenced the results. At the conference additional analyses will be presented.
Outcomes in hormone receptor positive, invasive lobular cancer in the era of endocrine monotherapy

Nicole Williams¹, Joseph Liu¹, Julie Stephens¹, Marilly Palettas¹, Hinda Boutrid¹, Sagar Sardesai¹, Raquel Reinbolt¹, Daniel Stover¹, Jeffrey VanDeusen¹, Anne Noonan¹, Robert Wesolowski¹, Maryam Lustberg¹ and Bhuvaneswari Ramaswamy¹. ¹The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Invasive lobular carcinoma (ILC) accounts for up to 15% of all breast cancers and is clinically and biologically distinct from invasive ductal carcinoma (IDC). Despite that, women with early stage ILC are often treated similarly to IDC. However, several retrospective studies suggest that patients (pts) with ILC may not derive survival benefit from the addition of chemotherapy to endocrine therapy relative to pts with IDC. The purpose of our study was to compare outcomes of pts with ILC treated with chemotherapy with those who received endocrine monotherapy.

Methods: A retrospective review of pts with ILC or pleomorphic lobular carcinoma treated at the Ohio State University James Cancer Center from 2004-2014 was performed. Clinico-pathologic characteristics, treatment summary and clinical outcomes were collected. Distant disease-free survival (DDFS) was defined as time from diagnosis to the first distant metastases or death and overall survival (OS) was the time from diagnosis to death or last known follow up. DDFS and OS curves were created using Kaplan-Meier methods and compared using log-rank tests. Cox proportional hazard models were used to calculate univariate and multi variable hazard ratios (HR) for OS and DDFS.

Results: We identified 379 pts with early stage ILC (stage I: 43% (162/379), stage II: 34% (127/379), stage III: 22% (84/379), unknown: 1% (6/379)). The majority of pts were post-menopausal (79%), Caucasian (92%) and ER+/PR+ (87%) and HER2 negative (96%). One hundred seventy six pts (46%) received chemotherapy and 189 (50%) pts received endocrine therapy alone. Pts who received chemotherapy had stage II or III disease, positive lymph nodes and grade 2 or 3 tumors; while pts who received endocrine monotherapy had stage I disease, negative lymph nodes and grade 1 or 2 tumors. We found a 51% decrease in chemotherapy (from 63% to 31%) and an increase in endocrine monotherapy use (from 34% to 65%) between 2004-2010 and 2011-2014. One hundred thirty two pts were evaluated with Oncotype DX, of which 76% (100/132) were node negative with the majority having a low recurrence score (low: 64%; intermediate: 33%; high: 3%). The use of Oncotype DX increased from 21.1% in 2004-2010 to 47.9% in 2011-2014. We found that 112 of 149 pts with at least 5 years follow up (75.2%) successfully completed five or more years of endocrine therapy.

Univariate cox models showed worse DDFS HRs for type of therapy and node status (HR: 2.36, p=0.005, HR: 4.16, p<0.001, respectively). However, the HR for therapy was no longer significant when adjusting for age, grade, and nodal involvement (HR = 1.19, 95% CI: 0.56 – 2.52, p=0.646). Nodal involvement remained significant (HR= 3.56, 95% CI: 1.64-7.70, p=0.001) after adjusting for therapy, age and grade. No significant difference in OS was found between endocrine monotherapy and chemotherapy (p=0.426, log-rank test).

Conclusion: We found no difference in DDFS between endocrine monotherapy and chemotherapy after adjusting for age, grade, and nodal involvement in pts with early stage ILC. This supports the hypothesis that ILC may not derive a significant benefit from the addition of chemotherapy. We need more prospective clinical trials considering histology to better understand how best to treat ILC.
Tamoxifen induced ovarian hyperstimulation during hormonal therapy for breast cancer

Min Kyoong Kim¹ and Hee-chul Shin¹. ¹Chung-Ang University Hospital, Seoul, Republic of Korea.

Introduction
Adjuvant endocrine therapy is an integral component of care for endocrine-dependent breast cancer. To date, international consensus statements recommend tamoxifen (20 mg/day) for five years as the standard adjuvant endocrine therapy for premenopausal women. Tamoxifen is a potent inducer of ovarian function and consequent hyper-estrogenism in premenopausal women. However, the incidence rate and risk factors associated with this phenomenon were not clarified.

Methods
Among consecutive patients who were operated under diagnosis of breast cancer from March 2012 to December 2016 in Chung-Ang university hospital, patients who received post-operative tamoxifen therapy for endocrine-dependent breast cancer (stage 0-III) at age under 60 were selected and retrospectively analysed. Serial data on serum estradiol and follicular stimulating hormone (FSH) were collected. When the serum concentration of estradiol was higher than 400 pg/mL, which exceeds the normal estradiol production by a single preovulatory follicle, we classified them as tamoxifen induced ovarian hyperstimulation group. Clinicopathologic factors were analyzed between ovarian hyperstimulation group and non-hyperstimulation group by χ² and student t-test.

Results
Among 205 patients, 19 patients (9.3%) showed high values of serum estradiol during tamoxifen therapy. They showed 44 times of high estradiol level during follow up period. The serum concentrations of estradiol and FSH were 1047.97 ± 38.8 pg/mL and 11.5 ± 7.3 mIU/mL, respectively. The mean duration from the start of the single administration of tamoxifen to the initial detection of a high concentration of estradiol was 666.4 ± 433.1 days.

Univariate and multivariate analysis between ovarian hyperstimulation and non-hyperstimulation groups showed younger age(<40 years) and only endocrine therapy without chemotherapy were related to higher prevalence of ovarian hyperstimulation significantly. (p <0.001, =0.031 each) Pathologic stages and progesterone receptor expressions on breast tumor were not related to manifestation of ovarian hyperstimulation.

Conclusions
The Incidence rate and occurrence time of ovarian hyperstimulation associated with adjuvant tamoxifen treatment in breast cancer patients under age 60 were 9.3% and around 2-year after treatment with tamoxifen. Young age under 40 years old and endocrine treatment without chemotherapy were risk factors predicting occurrence of ovarian hyperstimulation during tamoxifen treatment. It should be noted that tamoxifen is a potent inducer of ovarian function and close monitoring of the endocrine parameters during treatment with tamoxifen would be essential.
Clinicopathological features and endocrine therapy mode of ER low expression (1%-9%) breast cancer patients in China

Peifen Fu¹, Shuqian Wang¹, Minya Yao¹, Aizhai Xiang⁷, Jianbin Li², Haibo Wang³, Cuizhi Geng⁴, Feng Jin⁵, Yongmei Yin⁶, Xianhong Huang⁸ and Zefei Jiang². ¹The First Affiliated Hospital, Zhejiang University, School of Medicine, Hangzhou, China; ²The 307th Hospital of Chinese People’s Liberation Army, Beijing, China; ³The Affiliated Hospital of Qingdao University, Qingdao, China; ⁴Hebei Medical University Fourth Affiliated Hospital, Shijiazhuang, China; ⁵The First Hospital of China Medical University, Shenyang, China; ⁶Jiangsu Province Hospital, Nanjing, China; ⁷Hangzhou First People’ Hospital, Hangzhou, China and ⁸Hangzhou Normal University, Hangzhou, China.

Purpose: Since 2010, ASCO/CAP recommended that ER be considered positive if ≥1% tumor cells with positive nuclear staining by immunohistochemistry (IHC) in breast cancer. ASCO/CAP also recommended considering endocrine therapy (ET) in ER positive patients. However, most breast cancers are either ER negative or ER strongly positive (≥10%), and tumors with low ER (1-9%) expression are rare. Up to now, the effect of ET is controversial for these patients with ER 1-9% and unfortunately, we know little about the clinical information of this subgroup. In this study, we analyzed the clinicopathological characteristics and ET mode of patients with low ER expression. We sought to figure out whether the ASCO/CAP guidelines affect clinical ET decision in China and Which features are important considerations for doctors to choose ET. We also evaluated the efficacy of ET in these patients.

Methods: Patients diagnosed stage I-III primary invasive breast cancer with ER low expression (1-9%) between January 2008 and December 2016 were retrospectively identified from six hospitals in China. Result: 457 patients (2.7%) had low expression of ER (1-9%) of 17216 patients. Mean age at diagnosis was 49 years. 288 patients (49.9%) were younger than 50 years old. 254 patients (55.6%) had stage II disease and 37 patients (8.1%) had lymphovascular invasion (LVI). 260 patients (56.9%) were HER2 positive; 408 patients had PR negative or low expression; 327 patients’ (71.6%) Ki-67 status were > 20%. 388 patients (85%) received chemotherapy. Of those 388 patients, 90% patients received anthracycline combined with taxol chemotherapy regimens. 170 patients (37.2%) received ET. Before 2010, only 25.7% patients with low ER expression received ET. The proportion of ET increased after the 2010 ASCO/CAP guideline was published. In 2013, 50% patients received ET. The rate of ET was totally different in six hospitals. 55% patients received ET in the hospital with highest rate, while only 4% patients received ET in the hospital with lowest rate. Using the univariate logistic regression analysis of ET, ER expression, PR expression, Ki-67 status and LVI were associated with the rate of ET. But after adjustment for other covariates, only ER level was significantly associated with the rate of ET. Compared to patients with ER<5% tumors, patients with ER≥5% tumors had a significantly higher probability of ET rate (OR, 2.882; 95% CI: 1.928-4.308; P < 0.001). Median follow time was 30 months. The 5-year RFS rate was 85%. Younger age and positive lymph nodes were associated with worse RFS. Survival rate did not differ significantly between patients with or without ET (without ET vs with ET: OR, 0.870; 95% CI: 0.508-1.448; p=0.61). Conclusions: 2010 ACSO/CAP recommendation indeed result in an increase of ET rate for patients with 1%-9% ER positive. But these patients do not appear to benefit from ET. Prospective studies are needed for these patients and we need more accurate way to evaluate ER levels, which associate with endocrine response.
Prospective study analyzing value of breast Density change predicting ENdocrine therapy response in postmenopausal women taking adjuvant ARomatase inhibitor [DEAR study] (interim analysis)

Yumi Kim¹, Eunshin Lee¹, Han-Byoel Lee¹, Kyoung Eun Kim¹, Young Wook Ju¹, Ji Gwang Jung¹, Hyeong-Gon Moon¹, Dong-Young Noh¹,² and Wonshik Han¹,². ¹Seoul National University College of Medicine, Seoul, Korea and ²Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea.

Objective : To evaluate the value of breast density change of mammography and breast MRI as a predictive marker for a response to postoperative anti-hormone therapy by targeting ER-positive postmenopausal breast cancer patient

Methods : Density change of mammography, breast MRI density being taken just before start of anti-hormone therapy, mammography being performed after 6 months, 1 year, 2 years thereafter and breast MRI being performed 1 year after start of therapy will be measured by volpara and 3D-MR method. Molecular profile including ER expression level that has a relation with response rate to anti-hormone therapy will be analyzed and outcome will be evaluated based on disease free survival and overall survival.

Recurrence rate of each group was estimated based on the data of the patients in breast center of Seoul National University Hospital, 2006-2011, who underwent surgery of ER-positive breast cancer. Among 1065 persons, 7.5% (80/1065) showed recurrence rate and among these, recurrence rate of patients who took AI was 6.9% (12/175). Among these, based on MDR 5% cutoff, 1.6% vs 9.8% was represented. By designating recurrence rate as 1.5%, 9.5% and assuming dropout rate by refusal to clinical test as 10%, registration goal was set at total 411 persons based on each 137, 274 persons per each group.

Results : (this is interim analysis)

From 2012, total 156 patients are enrolled, among them, 32 patients were eliminated (affirmative consent, switched to Tamoxifen, recurrence and etc). From now total 124 patients are on-going to this study. Compare with Non AI group, breast density change of AI group is much decreased from base line study and it is statistically significant. (1 year follow up – base line, 2 year follow up– base line ; -12.2%, - 18.6% vs - 7.6%, -15.3% P-value 0.002, 0.009 respectively) Only one patient was relapsed within 5 year and there were no death. Psychological anxiety, medication compliance and side effects analysis were done. Psychological anxiety about disease and medicaiton were improved as time goes by (p<0.001). But medication compliance and side effects of AI were worsen. (p = 0.178, 0.015 respectively) Other topics will analyze. (DFS and OS, etc.)

Discussion :

70% of breast cancer is ER-positive breast cancer. Endocrine therapy (ET) has been clarified as an effective target therapy in large scale, prospective randomized trial and up to the present, it has been settled down as a standard therapeutic method of ER-positive breast cancer. As a result of 20 years’ follow-up after intake of AI (aromatase inhibitor) and 20 years’ follow-up after intake of tamoxifen, recurrence was represented as 2-2.5% and at present, clear mechanism of such resistance and predictive biomarker have not been clarified. Due to this resistance, all the ER-positive breast cancer patients are forced to receive anti-hormone therapy for 5 years or 10 years.

According to the taking AI, breast density is significantly decreased compare Non AI group. Of course need more follow up data and analysis, but we can confirm a meaning of endocrine responsiveness of breast density change being measured after anti-hormone therapy as predictive surrogate.
Acquired *ESR1* mutation and persistent expression of estrogen regulated genes in ER+ breast cancers on long-term neoadjuvant treatment with aromatase inhibitors

Mariana F Leal\(^1,2\), Ben P Haynes\(^2\), Eugene Schuster\(^1\), Belinda Yeo\(^2\), Maria Afentakis\(^2\), Andrew Dodson\(^1\), Richard Buus\(^1\), Maggie CU Cheang\(^1\), Lesley-Ann Martin\(^1\) and Mitch Dowsett\(^1,2\). \(^1\)The Institute of Cancer Research, London, United Kingdom and \(^2\)Royal Marsden Hospital NHS Trust, London, United Kingdom.

**Background:** Aromatase inhibitors (AI), which block the conversion of androgen to estrogen, are the mainstay therapy for estrogen receptor–positive (ER+) breast cancer (BC). However, many patients relapse.

**Purpose:** To identify molecular alterations associated with long-term neoadjuvant AI therapy of ER+ BC.

**Methods:** We retrospectively identified 137 patients diagnosed with ER+ BC and treated with neoadjuvant AI for at least 1 month at the Royal Marsden Hospital (2003–2016). Paired pre- (diagnosis) and post-AI (surgery) biopsies with >40% invasive cell areas were available from 87 ER+ BC patients. In all samples, we evaluated ER, PR and Ki67 immunostaining, *ESR1* hot-spot mutations by droplet digital PCR and expression of 801 genes associated with BC and response to endocrine therapy by NanoString.

**Results:** Mean time on neoadjuvant treatment was 26 weeks (range 5.6–92.3). Cell proliferation remained suppressed in most tumours indicating little evidence for acquired resistance: 56/87 (64%) showed residual Ki67 (Ki67r) <2.7% (complete cell cycle arrest) and 14/87 (11.5%) had Ki67r>10%. This was paralleled by reduced expression of proliferation genes, ER (immunostaining and gene expression) and estrogen-regulated genes (ERG) at surgery compared with the diagnostic samples (all p<0.001). There was a weak positive correlation between AI duration and Ki67r and less reduction in proliferation genes, *ESR1* and ERGs expression (p<0.05; r=0.26-0.34). Pathway analysis revealed inhibition of cell cycle (e.g. reduced expression of several cyclins), E2F targets and estrogen response (e.g. reduced expression of ER downstream targets such as *FOXM1*). CDK genes showed a variable response: *CDK1* and *CDK2* decreasing, *CDK4* increasing and no change in *CDK6*. Most notably, 6 surgical samples showed *ESR1* mutations: one of these cases had the mutation at diagnosis. All 5 acquired mutations were detected in patients treated for >6 months, giving a prevalence in this cohort of 5/34 (15%). Tumours with *ESR1* mutations showed less suppression of ERGs (p=0.002) and proliferation (p=0.039) and increased *ESR1* (p=0.016) expression at surgery compared with tumours without mutation. Pathway analysis confirmed lack of inhibition of estrogen response (FDR>5%) and less inhibition of cell cycle [enrichment score: -0.49 vs -0.78] and E2F targets [-0.47 vs -0.8] in tumours with mutation. Tumours without *ESR1* mutation but with Ki67r>10% also showed reduced ERGs response (p=0.006) compared to tumours with Ki67r<2.7%. Additionally, these tumours showed relative activation of cell cycle, estrogen response, E2F targets pathways and mTORC1 signalling (FDR<1%).

**Conclusion:** Overall most tumours showed no evidence for the emergence of resistant disease after neoadjuvant AI therapy even after many months of treatment. However, we detected an enrichment of *ESR1* mutations (15% of cases) after long-term treatment as a putative driver of ERG expression and proliferation and thus reduced AI response. Therefore, mutant ER appears to be associated with ligand-independent ERG activity supporting the clinical validity of dual blockade with a selective ER down-regulator combined with a CDK4/6 inhibitor targeting the RB/E2F axis in this scenario.
TILs variations, proliferative response and PEPI scores in patients with luminal breast cancer receiving neoadjuvant letrozole-palbociclib or chemotherapy: An extended analysis of the NEOPAL trial

Anne Vincent-Salomon1,2, Marie-Christine Mathieu3, Guillaume Bataillon1, Laurent Arnould4, Véronique Verrièle5, Jean-Pierre Ghnassia6, Juliette Haudebourg7, Frédérique Penault-Llorca8, Catherine Lefebvre9, Aurélie Maran-Gonzalez10, Jean-Marc Guinebretière11, Raphaëlle Duprez12, Anca Berghian13, Cécile Blanc-Fournier14, Valérie Calès15, Christine Galant16, Paul Delrée18, Jérôme Lemonnier17, Suzette Delaloge9 and Paul H Cottu1,2. 1Institut Curie, Paris, France; 2PSL Research University, Paris, France; 3Gustave Roussy, Villejuif, France; 4Centre George François Leclerc, Dijon, France; 5Institut de Cancérologie de l'Ouest, Angers, France; 6Centre Paul Strauss, Strasbourg, France; 7Centre Antoine Lacassagne, Nice, France; 8Centre Jean Perrin, Clermont-Ferrand, France; 9Institut Sainte Catherine, Avignon, France; 10Institut du Cancer de Montpellier, Montpellier, France; 11Institut Curie, Saint-Cloud, France; 12Institut Universitaire de Cancérologie de Toulouse, Toulouse, France; 13Centre Henri Becquerel, Rouen, France; 14Centre François Baclesse, Caen, France; 15Centre Hospitalier de Pau, Pau, France; 16Cliniques Universitaires Saint-Luc, Bruxelles, Belgium; 17Unicancer R&D, Kremlin Bicêtre, France and 18Institut de Pathologie et de Génétique, Charleroi, Belgium.

Background
The role of chemotherapy in early luminal breast cancer remains challenged. The NEOPAL trial (NCT 02400567; Cottu et al, ESMO 2017 LBA09) compared sequential chemotherapy (CT) and letrozole-palbociclib (LP) as neoadjuvant treatment in PAM50 defined high-risk luminal breast cancer patients, showing that LP might be as efficient as CT with regard to breast conserving surgery and pathological response. We report here extended exploratory pathological results, focusing on tumor infiltrating lymphocytes (TILs), proliferative response and preoperative endocrine prognostic index (PEPI) scores.

Material and Methods
Tumor blocks from baseline biopsy and surgical specimens were available for centralized review from the 106 randomized patients (53 in each arm). TILs quantification, Ki67 staining and counting, and ER quantification were performed according to standard methods. Residual proliferative cancer burden (RPCB) and PEPI scores were computed according to published algorithms. Wilcoxon rank sum test and Mann Whitney test were used to compare paired and unpaired data. The chi-square and Fisher exact tests were used for categorical variables.

Results
Overall, median TILs count did not differ between LP and CT patients, both at baseline (p=0.37) and at the end of treatment (p=0.42). Median TILs count climbed from 5% (0-60) to 10% (1-60) in the LP arm (p=0.0026) and from 2% (0-30) to 10% (0-60) in the CT arm (p=0.0023). Median Ki67 dropped sharply in both arms, from 30% (1-80) to 1% (0-30) in the LP arm (p=1.10e-8) and from 30% (2-80) to 5% (0-30) in the CT arm (p=3.10e-9). Decrease in the Ki67 geometric mean was as sharp. Of note, while baseline Ki67 was similar in both arms (p=0.315), decrease in the LP arm was significantly more profound than in the CT arm (p=0.00075). Pathological response according to RPCB were as follows, in the LP and CT arm, respectively: class 0: 9.6%/10.2%; class I: 84.6%/73.5%; class II: 5.8%/16.3%. The relapse free survival PEPI scores were as follow in the LP and CT arm, respectively: class I: 13.5%/16.3%; class II: 59.6%/46.9%; class III: 28.9%/36.8% (p=0.504). Breast cancer specific survival PEPI scores were as follow in the LP and CT arm, respectively: class I: 18.9%/8.2%; class II: 54.7%/40.8%; class III: 26.4%/51%. These results were significantly better in the LP arm (p=0.027). There was no correlation between final TILs quantification and the RPCB or PEPI scores.

Conclusions
In this prospective multicenter study with centralized pathological review, neoadjuvant letrozole-palbociclib combination generates impressive proliferative and endocrine specific response features. It compared well with chemotherapy. The LP combination also significantly increased lymphocytic infiltration. Its clinical significance and utility remain to be elucidated, but it potentially adds new prognostic and theranostic information.
Concurrent neoadjuvant chemotherapy and estrogen deprivation in patients with estrogen receptor-positive, human epidermal growth factor receptor 2-negative breast cancer (CBCSG-036): A randomized, controlled, multicenter trial

Ke-Da Yu and Zhi-Ming Shao. Fudan University Shanghai Cancer Center, Shanghai, China.

Background Limited studies existed to demonstrate clinical benefit from co-administration of neoadjuvant chemotherapy (NCT) and endocrine therapy by estrogen deprivation. Therefore, we conducted a clinical trial to investigate the efficacy of concurrent neoadjuvant chemotherapy (NCT) and estrogen deprivation in patients with estrogen receptor (ER)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer.

Methods In this open-label, multicenter, randomized controlled trial, eligible patients with stage IIB–IIIC, ER-positive, HER2-negative breast cancer (having indications for chemotherapy) were enrolled and randomly assigned to receive NCT with or without estrogen deprivation (an aromatase inhibitor with or without gonadotropin-releasing hormone-analogue according to menopausal status). The primary endpoint was the objective response rate (ORR, including complete response and partial response). The secondary endpoints included Ki67 proliferation marker changes, pathologic complete response, pathological response rate, progression-free survival (PFS), and safety. All analyses were by intention-to-treat principle.

Results From 2013 to 2017, 249 patients were randomly assigned to two groups, with 125 patients in the neoadjuvant chemo-endocrine therapy (NCET) and 124 patients in the NCT group. In the intention-to-treat analysis, the ORR was significantly higher in the NCET group than that in the NCT group (84.8% vs 72.6%, P=0.019; odds ratio=2.11, 95% confidence interval 1.13–3.95, P=0.020). The efficacy of concurrent estrogen deprivation was more prominent in tumors with higher Ki67 (Ki67 >20%), with ORR of 91.1% in NCET group vs 68.7% in NCT group (P=0.001). Although there is no significant difference of PFS between the two groups (P=0.188), patients with higher Ki67 at baseline might get more PFS benefit from concurrent NCT and estrogen deprivation (2-year PFS: 91.5% in NCET group vs 76.5% in NCT group, P=0.058). Adding endocrine agents to NCT was well tolerated and did not result in significant differences in adverse events (grade 3 or 4 toxicity) between two groups.

Conclusions Addition of estrogen deprivation to NCT improves the clinical response in patients with ER-positive, HER2-negative breast cancer, especially for those with higher Ki67. Although early survival analysis indicates that patients with higher Ki67 might get more PFS benefit from concurrent NCT and estrogen deprivation, longer follow-up will be necessary to fully evaluate survival benefit.
Neoadjuvant endocrine therapy for ER+ DCIS can lead to disease regression and allows BCS in up to a third of patients with disease >40mm at diagnosis

Christopher WJ Cartlidge¹, Neil Johns¹, Rosemary J Hackney¹, Arran K Turnbull² and J Michael Dixon². ¹Edinburgh Breast Unit, Western General Hospital, University of Edinburgh, Edinburgh, United Kingdom and ²Breast Cancer Now Edinburgh Research Team, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom.

**Background:** The role of neoadjuvant endocrine therapy (NET) for ER+ DCIS is an area of evolving study. It may allow down-sizing prior to surgery, converting DCIS requiring mastectomy to disease suitable for breast conservation surgery (BCS). Here we report the results from the first European single-institution series of its type.

**Methods:** Data were prospectively collected from patients diagnosed with ER+ DCIS and treated with NET prior to surgery, at a single unit between 2009 -2015. The size of the tumour on initial imaging (mammography) was compared to the size of the tumour on final imaging and pathology using RECIST criteria to determine disease progression. Blocks from initial core biopsy and final pathology are being interrogated by immunohistochemistry and DNA and RNA comparisons.

**Results:** 42 patients diagnosed with ER+ DCIS received NET with median age at diagnosis of 63y (range 37-94y). 7/42 premenopausal women were treated with tamoxifen, 35/42 post-menopausal women were treated with letrozole. 36/42 (85.7%) patients underwent surgery with 18/36 (50%) requiring mastectomy and 18/36 (50%) treated by BCS. 3/18 (16.7%) of the BCS patients required re-excision for positive margins. The median time to operation was 72d (range 15-308d). In total 12/42 (28.6%) had invasive disease on final pathology. 2/36 (5.6%) patients had a pathological complete response (PCR), 14/36 (38.9%) had a partial response (PR), 17/36 (47.2%) had stable disease and 3/36 (8.3%) had larger disease on pathology than imaging; this is a common feature of many lower grade DCIS lesions.

26/42 (61.9%) patients initially had DCIS >40mm (largest 240mm) and yet 9/26 (34.6%) of these patients still underwent successful BCS. There was a significant correlation between length of endocrine therapy and reduction in size of disease. Immunohistochemical and molecular analyses are ongoing.

**Conclusions:**
- NET is an effective treatment for ER+ DCIS. It reduces the rate of re-excision to 16.7% in this series - substantially lower than the national (UK) figures for DCIS at 30%.
- It produces path CRs (5.6%) and high response rates that relate to the duration of treatment.
- This unique study shows that the optimal duration of NET is of the order of 6 months, achieving high rates of conversion for mastectomy to BCS.
Biomarkers of response to neoadjuvant endocrine therapy with anastrozole (Ana) alone or in combination with fulvestrant (Ful) in ER-positive (ER+) HER2-negative (HER2-) breast cancer (PACT01 trial)

Sagar Dhamne1, Chandandeep Nagi1, Tao Wang1, Anne C Pavlick1, Brenda Reusser1, Racheal Schiff1, Nangia Julie1, Polly Niravath2, Eric J Silberfein1, Emily L Sedgwick1, Karla A Sepulveda1, Carolina Gutierrez1, Susan G Hilsenbeck1, Jenny C Chang2, C Kent Osborne1 and Mothaffar F Rimawi1.

1Baylor College of Medicine, Houston, TX and 2Houston Methodist Hospital, Houston, TX.

Background: In recent years, several clinical trials showed that fulvestrant (Ful), alone or in combination with an aromatase inhibitor (AI), is more effective than an AI alone. PACT01 is a randomized neoadjuvant trial of Anastrazole (Ana) alone or in combination with Ful in ER+/HER2- breast cancer.

Methods: Patients with newly diagnosed ER+/HER2- breast cancers, 2 cm or larger in size, were randomized to 16 weeks of Ana (1 mg orally every day) alone or in combination with Ful (500mg IM days 1, 15, 29, and every 28 days thereafter) for 16 weeks. Patients then proceeded to surgery. Tumor tissue was collected at baseline, day 28 (D28), and at the time of surgery. Primary endpoint was the reduction of Ki67 in tumor tissue between baseline and D28. Baseline and D28 samples were stained for ER, PR, HER2, and Ki67. ER and PR were scored for intensity and percentage (H-score), HER2 was scored for intensity of membrane staining; and Ki67 was scored as percentage. Data were summarized descriptively. Changes in biomarkers from baseline to D28 were calculated and compared by Wilcoxon signed rank test.

Results: PACT01 trial enrolled 72 patients. Three of them did not start treatment. Baseline samples were collected from the remaining 69 patients, and D28 samples from 60 patients (5 refused, 2 withdrew, 1 lost to follow up, 1 unknown). Samples from 18 patients had no tumor (5 at baseline, 9 at D28, 4 at both). Of the 42 patients with paired samples, 20 received Ana and 22 received Ana+Ful. All cases except one were centrally confirmed to be ER+, and all were HER2-. Table 1 summarizes median expression of Ki67, ER, and PR. Both treatment regimens led to a significant reduction in Ki67 between baseline and D28. However, Ana+Ful did not reduce Ki67 more effectively than Ana alone. Ki67 was reduced to <10% in 60% of the Ana arm and 68% of the Ana+Ful, which was not statistically significant. PR was similarly reduced in both treatment arms. ER was significantly reduced at D28 in the Ana+Ful arm (p=0.0004) but not in the Ana alone arm. Safety profile of both treatment arms was consistent with package insert and published studies.

*p=0.0004. Other comparisons were not statistically significant

Conclusions: In this small neoadjuvant trial, the addition of Ful to Ana did not increase Ki67 suppression at D28. This may be due to untreated primary tumors being exquisitely sensitive to Ana and that fulvestrant may not add to it. It is also possible that the effect of Ful may be noted later in the course of treatment. Further biomarker data on tissue collected at the end of treatment will be presented at the meeting.
Results of a randomized double blind trial of neoadjuvant anastrozole plus placebo vs anastrozole plus saracatinib for ER+ postmenopausal breast cancer

Joyce M Slingerland¹, Pegram Mark², Judith Hurley¹, Jose Net¹, Fernando Collado-Mesa¹, Marc Lippman¹, Eli Avisar¹, Monica Yepes¹, Merce Jorda¹ and Carmen Gomez¹. ¹Sylvester Comprehensive Cancer Center U of Miami, Miami, FL and ²Stanford Cancer Institute at Stanford University, Stanford, CA.

Antiestrogen mediated cell cycle arrest requires the CDK inhibitor, p27. Src kinase mediates p27 loss and antiestrogen resistance in ER+ breast cancer lines in vitro. In ER+ xenografts, the Src inhibitor, saracatinib, restored antiestrogen responses in resistant tumors. This led to a Phase I/randomized double-blind Phase II trial to test effects of saracatinib with anastrozole for ER+ and/or PR+ postmenopausal breast cancer.

Phase I accrued 12 subjects and showed 175 mg po saracatinib is safely given with 1 mg po daily anastrozole with good PK. In Phase II, postmenopausal women with new ER+ and/or PR+, HER2- breast cancers ≥ 2 cm were randomized 2:1 to either neoadjuvant anastrozole with saracatinib or anastrozole/placebo over 6 months. Response was assayed by clinical 2D measurements each cycle and by MRI pre-study, at 10 weeks and prior to surgery. The Phase II primary endpoint was to test if tumor volume decrease (from 2D clinical measures) with dual therapy (dual) exceeded that of monotherapy (mono) by >20%. Secondary endpoints included tumor response by 3D MRI measures and by RECIST, PK and toxicity, and molecular predictors of drug efficacy in pre-/ post-therapy tumors. Of 58 subjects, 15% were Black, 5% Asian and 79% White. 61% were Hispanic. Dual therapy was well tolerated, with the following grade 1 toxicities: flu-like syndrome 20%, non-pruritic rash 48% (17% for mono), self-limited diarrhea in 55% (33% mono). Transaminasemia with dual therapy was 52.5% and 17% with mono. 6/59 stopped dual due to drug related AEs: 2 had gr 3 hepatitis, one gr 3 anemia, 3 had grade 3 urticarial rash. Dual Rx increased mean anastrozole levels to 50 ng/ml vs 38 ng/ml for mono (T test p= 5.45201 E-05). Mean saracatinib level, 269 ng/ml, was similar to prior studies. All of 50 evaluable subjects showed clinical and MRI tumor responses. 17% in both groups progressed, usually after 16 weeks. Mean tumor vol (calculated from 2D clinic measures) declined more rapidly (by 63% in dual vs 55% in mono at 8 weeks), but both groups showed an 89% mean tumor volume decrease by 20 weeks. Clinical RECIST showed size reductions of 61% in dual and 62% after monotherapy. Tumor volumes based on 3D MRI show a non-significant trend to greater response to dual therapy, with mean volume decreased by 64% vs 45% at the end of dual vs monotherapy. RECIST response by MRI also showed a trend to greater % decrease tumor size post treatment by 34% vs 25% in dual vs mono. Thus, clinical volumetric assessment of response to this neoadjuvant endocrine therapy may overestimate response compared to volumes calculated by MRI, while RECIST may underestimate it. Pathologic responses based on initial and residual tumor burden calculated from initial and final tumor volumes and % cellularity in biopsy and surgical specimens will be presented.
A randomized, double-blind, placebo-controlled trial of testosterone (T) for aromatase inhibitor-induced arthralgias (AIA) in postmenopausal women: Alliance A221102

Roberto A Leon-Ferre¹, Jennifer Le-Rademacher¹, Shelby Terstriep², Rebecca Glaser³, Paul Novotni¹, Armando Giuliano⁴, M Sitki Copur⁵, Cheryl Jones⁶, Seth Page⁷, William Mitchell⁸, Stephen N Birrell⁹ and Charles L Loprinzi¹. ¹Mayo Clinic, Rochester, MN; ²Sanford Broadway Medical Center, Fargo, ND; ³Wright State University, Dayton, OH; ⁴Cedars-Sinai Medical Center, Los Angeles, CA; ⁵Saint Francis Cancer Treatment Center, Grand Island, NE; ⁶Georgia Cancer Specialists PC, Macon, GA; ⁷Cancer Center of Kansas-Wichita Medical Arts Tower, Wichita, KS; ⁸Novant Health Presbyterian Medical Center, Charlotte, NC and ⁹Havah Therapeutics Pty Ltd, Toorak Gardens, South Australia, Australia.

Background: Aromatase inhibitors are a mainstay hormone receptor-positive breast cancer treatment. AIA occur in up to 50% of patients (pts), adversely affecting quality of life and treatment compliance. A small phase II clinical trial of oral testosterone undeconate appeared to improve AIA over placebo (P), with no significant androgenic side effects. The current study was performed to confirm these findings.

Methods: This randomized P-controlled trial enrolled postmenopausal women on adjuvant anastrozole or letrozole and experiencing moderate-to-severe AIA (≥5 on 0-10 scale). Pts were initially randomized to receive a subcutaneous pellet containing T 120 mg + anastrozole 8 mg (T+AIpellet) or P at the end of the first week on study (after obtaining baseline hot flash data) and at 3 months (mo). Due to slow accrual, the protocol was amended to change the route of delivery to topical T or P applied to the skin once daily for 6 mo. Baseline and monthly questionnaires were administered, including: Modified Brief Pain Inventory for aromatase arthralgia (BPI-AIA), profile of mood states (POMS), the menopause specific quality of life questionnaire (MENQOL), a hot flash diary, the hot flash related daily interference scale (HFRDIS) and a symptom experience questionnaire. The primary endpoint was intra-patient change in joint pain at 3 mo, compared using a two-sample t-test.

Results: 227 pts were accrued between 9/1/2013-11/29/2017. 55 pts were randomized prior to the protocol amendment and received T+AIpellet or P. Baseline characteristics were balanced between arms, with the exceptions of median weight, BMI, hemoglobin (all higher in T arm), and breast tenderness, dissatisfaction with personal life/depression, and skin changes (all higher in P arm). Compared to baseline, there were no significant differences between T and P in average pain or joint stiffness at 3 (p=0.483) or 6 mo (p=0.573). Average pain was significantly lower each month compared to baseline, irrespective of treatment arm. There were no significant differences in any other items evaluated by BPI-AIA, POMS, MENQOL, hot flash diary or HFRDIS. Similarly, there were no substantial differences in toxicity. A subset analysis of the 55 pts randomized to receive T+Alpellet or P identified significant reductions in average pain scores with T+Alpellet during the first month (p=0.038), but not thereafter. T+Alpellet pts had significantly more reduction in reported % of baseline hot flash frequency (p=0.034) and score (p=0.031), nausea (p=0.019), fatigue (p=0.042), mood swings (p=0.026), hand/feet swelling (p=0.009), stress urinary incontinence (p=0.039) and changes in appearance, texture or tone of their skin (p=0.0083), than pts on P.

Conclusions: Overall, T did not improve AIA or menopausal symptoms compared to P. While there was significant improvement in AIA over the study period, T did not facilitate this process. However, T+Alpellet was associated with improvement in short-term AIA and several menopausal symptoms compared to P, suggesting that subcutaneous T combined with anastrozole may be superior to transdermal T alone.

Fertility preservation before neoadjuvant or adjuvant chemotherapy for breast cancer: Final results of PRESAGE trial

Virginie Bordes¹, Clement Palpacuer¹, Camille FRICK², Florence Leperlier², Aliette Dezellus¹, Pascarine De Blay³, Fabienne Delay³, Baptiste Sauterey⁴, Paule Augereau⁴, Solene Duros⁵, Claudia Lefeuvre-Plesse⁶, Sophie Lavau⁷, Lise Marie Durand⁷, Marie Ange Mouret⁸, Anne Sophie Gremeau⁹, Mario Campone¹ and Sophie Mirallie². ¹ICO Rene Gauducheau, Nantes, France; ²CHU, Nantes, France; ³CHD, La Roche sur Yon, France; ⁴ICO Paul Papin, Angers, France; ⁵CHU, Rennes, France; ⁶Centre Eugene Marquis, Rennes, France; ⁷CHU, Limoges, France; ⁸Centre Jean Perrin, Clermont Ferrand, France and ⁹CHU, Clermont Ferrand, France.

Background: Breast cancer is the most frequent form of cancer in young women. For these patients, breast cancer is generally more aggressive and chemotherapy is more often needed. Chemotherapy is commonly associated with amenorrhea and a decrease of ovarian reserve depending on the patient's age, agents and dose. Embryo, oocyte and ovarian tissue cryopreservation are the three options to preserve fertility. Embryo and oocyte cryopreservation require controlled ovarian stimulation (COS). The use of COS is associated with an increase of estradiol levels. It led to develop protocols using Tamoxifen or Letrozole combined with FSH to protect patients of the potential deleterious effects of the COS. PRESAGE is the first French prospective multicenter feasibility study about fertility preservation by COS combined with Tamoxifen and oocyte +/- embryo cryopreservation before neoadjuvant (NAC) or adjuvant (AC) chemotherapy for breast cancer.

Material and method: Prospective multicenter study for patients of less than 40 years, with a breast cancer, for whom a treatment of NAC or AC is indicated and who wish to preserve their fertility. The main objective was to evaluate the feasibility of a COS associating Tamoxifen with FSH followed by an oocyte+/- embryo cryopreservation. The secondary objectives were to evaluate the average deadline prior to the beginning of the chemotherapy and the impact of the type of COS (depending on the phase of the menstrual cycle, conventional-start or random-start COS protocol) on the number and the quality of oocytes harvested.

Statistical analysis was performed using SAS statistical software version 9.4 (SAS Institute, Cary, NC).

Results: 101 patients were included between February 2014 and July 2017 and 97 patients were eligible for statistical analysis. Mean age of the patients was 31,5 +/- 4 years, the half of them was nulliparous (53/97) and 23,7 % (23/97) were single. They presented mainly SBR II or III (91/96, 94,8 %) lesions, ER + (66/96, 68,7 %). 38 patients benefited from a NAC and 59 of an AC. We have found a significant shorter care (time between the first oncologist's consultation and the beginning of the chemotherapy) according to the type of chemotherapy: 29,7 +/- 15,6 days in NAC group vs 45,2 +/- 21,5 days in AC group (p=0,003) with the same duration of ovarian stimulation in the two groups (10,5 +/-2 days).

The success rate of the COS procedure was 90,7 % (88/97) with no significant difference between the groups according to the type of COS (p = 0.06) or the type of chemotherapy (AC vs. NAC p= 0.3). In the 88 patients who had oocyte retrieval, the number of oocytes harvested per patient was 12,8 +/- 7,8 , the number of oocytes preserved was 9,7 +/- 6,1 and an IVF was performed in 12,5% of patients (11/88) with 5,1 +/- 3,1 embryos obtained. We have found no impact of the type of chemotherapy or the type of COS on the number of oocytes or embryos preserved.

Conclusion: with a high success rate (90,7%), our study suggests that COS with Tamoxifen and FSH is feasible before adjuvant or neoadjuvant chemotherapy in breast cancer patients. We also show that COS procedure before neoadjuvant chemotherapy can be realized without increasing the time before introducing chemotherapy.
Cardiovascular outcomes and long term survival with discontinuation of adjuvant trastuzumab

Sagar Sardesai¹, Joseph Liu¹, Marilly Palettas¹, Julie Stephens¹, Daniel Stover¹, Nicole Williams¹, Raquel Reinbolt¹, Jeffery VanDeusen¹, Robert Wesolowski¹, Maryam Lustberg¹ and Bhuvaneswari Ramaswamy¹. ¹The Ohio State University Comprehensive Cancer Center, Columbus, OH.

Background: Trastuzumab (T) induced cardiomyopathy remains a significant limitation to adjuvant HER2 directed therapy. Recent studies have aimed to reduce cardiotoxicity through combination with non-anthracycline (non-A) chemotherapy or shorter treatment duration. However there is limited data regarding cardiac outcomes and long-term survival with early discontinuation of adjuvant T.

Methods: An IRB-approved single-institution retrospective analysis was performed for 401 consecutive patients with non-metastatic HER2+ breast cancer treated at the Ohio State University Comprehensive Cancer Center from 2005-2015. Medical records were reviewed for clinicopathologic features, systemic treatment and survival information. Disease Free Survival (DFS) was defined as time from diagnosis to first recurrence (loco-regional or distant recurrence) including second primary breast cancer or death. Overall survival (OS) was defined as time from diagnosis to death or last known follow up. OS and DFS estimates were generated using Kaplan Meier methods and compared using Log-rank tests. Cox proportional hazard models were used to calculate univariate and multivariate hazard ratios for OS and DFS.

Results: A total of 371/401 (92.5%) patients received adjuvant T (n= 401, mean age: 59.4 years; stage I: 120, 30%; stage II: 194, 48%; stage III: 87, 22%; ER+: 235, 58%); among whom 106/371 (28.6%) patients held adjuvant T for any reason.

Table 1- Discontinuation of adjuvant trastuzumab

<table>
<thead>
<tr>
<th>Number of patients (%)</th>

<td>Initial treatment</td>
</tr>
<tr>
<td>Completed therapy with no interruption</td>
</tr>
<tr>
<td>Interruption of therapy for minimum of 2 weeks</td>
</tr>
<tr>
<td>Permanently discontinued</td>
</tr>
</tbody>
</table>

Median duration of therapy in patients with any interruption with T was 11.3 (0.5-16.9) months and 23/371 (6.9%) received less than 6 months of adjuvant T. Cardiomyopathy (measured as LVEF decline on 2D echocardiogram or MUGA >= 15 points) was the most common reason for withholding T (66/106, 62.3%). The majority of these patients received a cardiology referral (77/ 106, 72.6%) with a 13 day mean time to evaluation in outpatient clinic. Patients receiving non-A chemotherapy and beta blockers or ACE inhibitors during treatment were significantly less likely to experience cardiomyopathy (A vs non-A: 49/190, 25.8% vs. 16/136, 11.8% p=0.002); (Med vs no Med: 7/148, 4.73% vs 59/184, 32.1%; p<0.001). Log-rank tests indicate a significant worsening in OS and DFS for patients who discontinued T (p=0.021, 0.001 respectively). Multivariate analyses confirmed significant worsening in DFS after adjusting for age, stage, ER , node status, and cardiomyopathy (Adjusted HR: 4.0[2.02 – 7.92], p< 0.001)

Conclusion: Discontinuation of adjuvant trastuzumab, most often from cardiomyopathy, is an independent prognostic marker for worse DFS in non-metastatic HER2 positive breast cancer. Non-anthracycline chemotherapy and use of cardio-protective medication is associated with significantly reduced incidence of cardiotoxicity in this population. Future prospective studies should consider optimizing cardiovascular function to avoid interruption in adjuvant HER 2 directed therapy.
Oral ibandronate for osteopenic breast cancer patients receiving adjuvant aromatase inhibitors: secondary 5-year survival outcomes analysis of the single-center phase 2 BONADIUV trial

Icro Meattini¹, Vieri Scotti¹, Isacco Desideri¹, Calogero Saieva², Luca Visani¹, Viola Salvestrini¹, Sara Cecchini², Maria Laura De Feo³, Matteo Mariotti¹, Emanuela Olmetto¹, Camilla Delli Paoli¹, Giulio Francolini¹, Marco Bernini¹, Lorenzo Orzalesi¹, Luis Sanchez¹, Jacopo Nori¹, Simonetta Bianchi¹ and Lorenzo Livi¹. ¹AOU Careggi Hospital - University of Florence, Florence, Italy; ²Istituto per lo Studio, la Prevenzione e la Rete Oncologica (ISPRO), Florence, Italy; ³Onco-Hematology Unit - Policlinico San Marco-IOB, Zingonia, Bergamo, Italy and ⁴UOSD Diabetologia Endocrinologia, Ospedale S. Giuseppe, Empoli, Florence, Italy.

Background. Several randomized trials demonstrated aromatase inhibitors (AI) superiority in terms of disease-free survival (DFS) compared to tamoxifen treatment for postmenopausal hormone receptor-positive breast cancer (BC) patients. Anyway, AI toxicity profile is a concern due to estrogen suppression. Pivotal trials demonstrated a significant bone mineral density (BMD) loss due to AI, with a consistent 5-year risk of bone fractures, thus impacting on patients' quality of life. Bisphosphonates represent an effective treatment in postmenopausal osteoporosis fractures prevention. However, an adequate patient's selection for adjuvant bisphosphonates treatment during AI endocrine therapy is still a challenge. Final results of BONADIUV trial presented at San Antonio Breast cancer Symposium in 2016 showed that treatment with ibandronate, as compared to placebo, significantly improved BMD change in osteopenic women treated with adjuvant AI, and consistently protected patients' bone loss. We present the secondary 5-year analysis on survival outcomes of the trial.

Patients and methods. The BONADIUV trial is a single-blind, randomized, placebo-controlled phase 2 study designed to evaluate the impact of ibandronate treatment on BMD in osteopenic women taking AI. Between January 2011 and May 2014, 171 osteopenic patients (lumbar spine [LS] and/or trochanter -1< T-score <-2.5), were randomized in a 1:1 ratio to receive either placebo or oral monthly ibandronate (150 mg). Treatment duration was 2 years, with 6-months evaluation. Primary endpoint was the mean BMD difference between the two arms at a 2-year follow up. Secondary analysis on survival outcomes (overall survival [OS] and invasive DFS [iDFS]) have been performed at 5-year median follow-up time. ClinicalTrials.gov identifier: NCT02616744.

Results. At the database cutoff time for the present analysis on May 4, 2018, median follow up was 63.3 months (mean 61.2; range 2.7-87.3) for whole series, 64.9 months (range 33.8-84.0) for the placebo arm, and 62.2 months (range 24.2-87.3) for the ibandronate arm. Ten patients in the placebo group and 17 patients in the ibandronate group withdrew the allocated arm before any follow up data collection, and so were excluded from the analysis, performed on 144 patients (72 patients per arm). At the database cutoff time, the OS rate was 97.2% in the placebo group and 100% in the ibandronate arm. We observed four loco-regional relapse (three in the placebo arm, one in the ibandronate arm; p=0.33), three distant metastases (none in the placebo arm, three in the ibandronate arm; p=0.075), and three contralateral BC (one in the placebo arm, two in the ibandronate arm; p=0.65). The number of iDFS events did not differ between groups: four in the placebo group and six in the ibandronate group (p=0.56). Up to data cutoff, two deaths have occurred; none in the placebo arm and two in the ibandronate arm (p=0.15). The OS rate did not differ between arms.

Conclusions. The secondary analysis of survival outcomes showed no difference between arms in terms of OS and iDFS rates. Further large investigations and mature follow-up from the published ones are awaited.
Avoidable acute care use associated with nausea and emesis among patients receiving AC, carboplatin, or cisplatin for breast cancer

Kathryn J Ruddy,1 Eric J Roeland,2 Thomas W LeBlanc3, Gary Binder4, Silvia Sebastiani5, Ravi Potluri6, Luke M Schmerold6, Eros Papademetriou8 and Rudolph M Navari7. 1Mayo Clinic, Rochester, MN; 2Massachusetts General Hospital, Boston, MA; 3Duke University School of Medicine; Duke Cancer Institute, Durham, NC; 4Helsinn Therapeutics US, Iselin, NJ; 5Helsinn Healthcare, Lugano, Switzerland; 6SmartAnalyst, New York, NY and 7University of Alabama Birmingham School of Medicine, Birmingham, AL.

Background: In order to improve care and reduce costs of cancer treatment, attention has focused on reducing inpatient (IP) and emergency room (ED) utilization. The US Centers for Medicare and Medicaid Services (CMS) recently implemented an oncology outcome measure (OP-35) to assess the quality of care and determine outpatient hospital payment. It assesses 30-day post-chemotherapy rates of IP or ED events deemed “potentially avoidable” by CMS due to association with any of 10 CMS-defined toxicities: anemia, dehydration, diarrhea, fever, nausea, emesis, neutropenia, pain, pneumonia, or sepsis. Although CMS found that 20% of chemotherapy treatment resulted in such events, event rates with highly emetogenic chemotherapy (HEC) are understudied, particularly for breast cancer (bCA) patients treated with anthracycline + cyclophosphamide (AC), carboplatin, or cisplatin.

Methods: In a large electronic health record database focused on US integrated delivery networks, HEC courses of therapy were identified from 4Q 2012 to 3Q 2017. IP/ED events within 30 days of chemotherapy administration were considered related to the OP-35 measure if they included a diagnosis code of any of the ten OP-35 toxicities, per CMS' definitions. HEC chemotherapy use, IP/ED events, bCA diagnosis, and toxicities were identified by ICD-9, ICD-10, and procedural codes. Subgroups were evaluated for 3 common HECs: AC, carboplatin (>14 days apart, as a proxy for AUC $\geq$4), and cisplatin.

Results: 4128 courses of HEC in bCA were identified. Of these, 2304 involved AC (median 4 cycles), 1721 involved carboplatin (median 6 cycles), and 103 involved cisplatin (median 4 cycles), with median ages of 55, 59, and 64, respectively. 30-day IP/ED events were seen in 25% of these HEC bCA courses (22%, 30% and 23% for AC, carboplatin, and cisplatin, respectively). The 10 CMS-defined toxicities were associated with an IP/ED event for 73%, 72%, and 76% of events for these AC, carboplatin, and cisplatin courses respectively, confirming that these are principal contributors to 30-day IP/ED use for patients receiving HEC in bCA. The top five that were most commonly associated with IP/ED for bCA for patients receiving AC, carboplatin, or cisplatin were pain 53%/49%/63%, anemia 51%/51%/38%, fever 48%/31%/38%, neutropenia 46%/27%/31%, and nausea/emesis 30%/40%/25%; patients may have had $\geq$1 toxicity associated with each IP/ED event. The IP/ED rate may be understated because some events, particularly ED, may occur out of the network the EHR data covers.

Conclusion: One quarter of patients receiving AC, carboplatin, or cisplatin for bCA visit the ED or are hospitalized within 30 days of at least one of their chemotherapy administrations. Most events involved $\geq$1 of 10 toxicities deemed avoidable causes of hospitalization by CMS and now tracked as an oncology outcome measure. Relative to patients receiving AC, acute care rates for patients receiving carboplatin were lower for fever and neutropenia and higher for nausea/emesis, perhaps because the study period largely precedes the 2017 addition of carboplatin AUC $\geq$4 to national guidelines as HEC requiring triplet antiemetic prophylaxis. Toxicity prevention and symptom monitoring are crucial to reduce acute care needs.
Incidence of interstitial lung disease in patients with HER2-positive advanced breast cancer treated with everolimus and trastuzumab: A combined analysis of two phase 3 randomized controlled trials

Kyaw Z Thein1, Sriram Swarup1, Anita Sultan1, Lukman Tijani1, Nicholas D'Cunha1, Fred TempPhilip.dbo.OAS_ Hardwicke1, Sanjay Awasthi1 and Catherine Jones1. 1Texas Tech University Health Sciences Center, Lubbock, TX.

Background: The human epidermal growth factor receptor 2 (HER2) protein is overexpressed in approximately one fourth of breast tumors. Trastuzumab resistance has been demonstrated via aberrant PI3K/AKT/mTOR signaling due to PTEN loss. To circumvent this resistance mechanism, everolimus, an oral mTOR inhibitor, has been employed in treatment of HER2-positive advanced breast cancer (ABC). Lung toxicity due to everolimus is well established and has been reported with trastuzumab. Yet, the incidence of interstitial lung disease (ILD), when everolimus was added to trastuzumab, has never been reported. We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) to determine the incidence of ILD in patients with HER2-positive ABC treated with both everolimus and trastuzumab.

Methods: We systematically conducted a comprehensive literature search using MEDLINE, EMBASE databases and meeting abstracts through January 2018. Phase 3 RCTs that mention ILD as an adverse effect were incorporated in the analysis. The primary meta-analytic approach was a fixed effects model using the Mantel-Haenszel (MH) method. It was used to calculate the estimated pooled risk ratio (RR), and risk difference (RD) with 95% confidence interval (CI).

Results: A total of 1272 patients with HER-2 positive ABC from two phase 3 RCTs were eligible. Studies compared everolimus + paclitaxel + trastuzumab vs paclitaxel + trastuzumab and everolimus + vinorelbine + trastuzumab vs vinorelbine + trastuzumab. The initial dose of everolimus in BOLERO-1 was 10mg per day and in BOLERO-3, 5mg per day was used. The median relative dose intensity of everolimus was reduced to 0.54 in BOLERO-1 due to toxicity related dose reductions and dose interruptions. The randomization ratio of everolimus to placebo was 2 to 1 in BOLERO-1 and 1 to 1 in BOLERO-3. Everolimus was utilized in trastuzumab-resistant ABC after prior taxane therapy in the BOLERO-3 study (n= 562) and as first-line treatment in the BOLERO-1 study (n= 710). The I² statistic for heterogeneity was 0, and the heterogeneity X² (Cochran's Q) was 1 (P= 0), suggesting homogeneity among RCT. The incidence of all-grade ILD was 31 (4.122%) in the everolimus group vs 3 (0.577%) in control group and of high-grade ILD was 11 (1.463%) in everolimus arm vs 0 (0%) in the control arm. The pooled RR for all-grade ILD was significant at 7.258 (95% CI: 2.130 – 24.733, p = 0.002) and the absolute RD was 0.035 (95% CI: 0.019 – 0.050, P < 0.001). The pooled RR for high-grade ILD was noted at 7.930 (95% CI: 0.997 – 63.044, p = 0.050) and the absolute RD was 0.014 (95% CI: 0.004 – 0.024, P = 0.004).

Conclusions: Approximately 0.46 and 0.61% of patients on trastuzumab alone have been reported to develop ILD in previous studies. Our study showed that the addition of reduced dose of everolimus to trastuzumab, significantly contributed a higher incidence in all grades of ILD with a relative risk of 7.93 for grade 3 and 4 ILD. More randomized trials are required to determine the definitive incidence and actual relation of ILD as well as the optimal dose of everolimus, when combined with trastuzumab or other chemotherapy.
The CHANCE study: Mechanical skin changes among women with non-metastatic breast cancer receiving chemotherapy and endocrine therapy

Mario E Lacouture¹, Gregory S Phillips¹, Azael Freites-Martinez¹, Sujata Patil², Andrea Samuels¹, Jerry Shapiro³, Oluwaseun Kukoyi¹ and Shari Goldfarb¹. ¹Dermatology and Breast Cancer Medicine Service, Memorial Sloan Kettering Cancer Center, New York, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY and ³The Ronald O. Perelman Department of Dermatology, New York University School of Medicine, New York, NY.

Background: The persistent effects on skin hydration and elasticity resulting from cytotoxic and endocrine agents used in early stages of breast cancer are poorly understood. The objective of this preliminary analysis of the CHANCE study is to describe the pattern of persistent biomechanical skin changes in non-metastatic breast cancer patients treated with cytotoxic chemotherapies and/or endocrine therapies.

Methods: This is an ongoing single-center, prospective, longitudinal cohort study of non-metastatic breast cancer patients treated with cytotoxic chemotherapies and/or endocrine therapies. Objective skin hydration and elasticity measurements of the forearm were measured using Tewameter® (TM 300; Courage & Khazaka) and Cutometer® (MPA 580; Courage & Khazaka) devices under a controlled ambient environment at baseline and 6 months after chemotherapy completion, or one year after initiation of endocrine therapy.

Results: A total of 107 patients were assessed at baseline and follow-up for transepidermal water loss (TEWL) (median age 53, range 26-82) and 106 patients for skin elasticity (median age 53.5, range 26-82). Fifty-three healthy controls were evaluated at baseline with median age 47 (range, 22-73). The mean TEWL at baseline and follow-up among patients were 6.922 g/h/m² and 8.521 g/h/m², respectively (p<.0001). Skin firmness (0.420 versus 0.421 mm, p=0.949) and elasticity (77.2% versus 77.4%, p=0.836) did not significantly change during follow-up. When comparing chemotherapy recipients with endocrine therapy recipients, chemotherapy patients had a mildly lower TEWL at follow-up (8.369 versus 8.928 g/h/m², p=.247) but a greater net increase in TEWL (1.687 versus 1.359 g/h/m², p=.5) compared to endocrine patients over the study period.

Conclusions: An increase in TEWL was observed in patients receiving cytotoxic and endocrine therapies, suggesting a deterioration of the protective skin barrier possibly attributed to these therapies. No significant changes in skin firmness or elasticity were found in this preliminary analysis. Further studies are needed to elucidate the pathophysiologic mechanisms involved in persistent skin changes after systemic breast cancer therapies.

A regional audit of 6-hour monitoring for administration related reactions during the first administration of subcutaneous trastuzumab

Soheilali Karmali¹,², Niamh Hughes¹, Ada Kinneally⁴, Jeska Kroes⁴, James Cook¹, Michael Killian¹, Tahir Shafiq⁵, Deirdre O’Mahony³,⁵, Brian Bird², Miriam O’Connor⁴, Seamus O’Reilly⁵, Raimundas Galiauskas² and Conleth G Murphy². ¹Bon Secours Hospital, Cork, Munster, Ireland; ²University College Cork, Cork, Munster, Ireland; ³Cork University Hospital, Cork, Munster, Ireland; ⁴University Hospital Waterford, Waterford, Ireland and ⁵University Hospital Kerry, Tralee, Kerry, Ireland.

Introduction
In 2012, Subcutaneous Trastuzumab (TSC) was introduced as an alternative to Intravenous Trastuzumab (TIV) for HER2+ breast cancer. The pivotal HannaH study demonstrated that TSC was non-inferior to TIV, was preferred by patients, and serious administration related reactions (ARRs) were not reported. However, the Summary of Product Characteristics (SPC) advises that patients be observed for ARRs for 6 hours post-first administration (and 2 hours post-subsequent administrations), similar to TIV.

Aim
To assess the frequency and tolerability of ARRs during the 6-hour observation period post first administration of TSC in patients with HER2+ breast cancer.

Method:
A retrospective audit of TSC was conducted in Southwest Ireland across five centers from 2014-2016. Patient charts were reviewed to record ARRs reported on the first-administration or at subsequent visit. In addition a subset of patients were interviewed regarding their recollection of ARRs with first or subsequent injections.

Results:
The study is ongoing having identified 192 patients. These centers have administered 2111 TSC injections in total, associated with 4998 hours of observation as per SPC. From the 385 injections given over the first two TSC administrations, 13 injections (3.4%) were associated with ARRs within 24 hours. Nine patients (2.3%) experienced injection site reactions immediately post injection, one injection site pain (0.3%), and one experienced petechiae on subsequent exposure (0.3%). Three patients experienced pyrexia and dry cough 24 hours post-injection and were hospitalized for respiratory tract infection. There were no reactions experienced between 2 and 6 hours post-first injection. There were no serious ARRs. Telephone interviews are ongoing and these results will be reported.

Conclusion:
ARRs related to TSC are usually immediate, mild and self-limiting. Observing patients for 6 hours post-first injection and 2 hours post-subsequent injections represents an inefficient use of healthcare resources.
Effect of simvastatin on cardiac strain in breast cancer patients receiving anthracycline therapy

Karen L Smith1, Jan M Griffin1, Hua-Ling Tsai5, Margaret Leathers1, Allison Hays1, Dai-Yin Lu6, Zhe Zhang5, Gary L Rosner5, Stuart D Russell9, Roisin M Connolly1, Danijela Jelovac1, Kala Visvanathan1, Antonio C Wolff1, Vered Stearns1 and Theodore Abraham2. 1Johns Hopkins University School of Medicine, Baltimore, MD; 2University of California San Francisco, San Francisco, CA; 3Duke University, Durham, NC; 4Johns Hopkins Hypertrophic Cardiomyopathy Center for Excellence, Baltimore, MD and 5Johns Hopkins, Baltimore, MD.

Background: Cardiac toxicity (CT) is a rare late effect of anthracycline therapy for breast cancer (BC). Statins may attenuate the CT of anthracyclines. Myocardial strain can detect subclinical CT before ejection fraction (EF) declines. Global longitudinal strain (GLS) ≥-19% and relative change (RelΔ) in GLS≥11% predict future decline in EF. We conducted a pilot study to evaluate the effect of simvastatin on GLS in BC patients receiving anthracyclines. Methods: We enrolled women with stage I-III BC planning doxorubicin/cyclophosphamide (AC) x 4. Women with heart disease or taking a statin were excluded. Participants were randomized 1:1 to simvastatin 40 mg daily x 24 weeks (wk) + AC or to AC alone. We performed echo with strain 5 times: baseline (BL), pre-AC#2, 1-3 wk after AC#4, 24 wk after AC #1 and 52 wk after AC#1. The primary endpoint was the mean absolute change (|Δ|) in GLS from BL to 1-3 wk after AC#4. Secondary endpoints included RelΔ in GLS, feasibility and safety. We used two-sample t-tests to compare mean changes in GLS and Fisher’s exact test to compare dichotomized GLS values. The study closed early due to loss of staff. Results: Of 31 patients, 15 (48%) received simvastatin+AC. Mean age was 46 years; 71% pre-menopausal, 61% white and 32% black. There were no significant differences in BL cardiovascular risk factors between the arms. After AC, 3 HER2+ patients received trastuzumab. There were no grade 3-4 AEs with simvastatin. Common grade 1-2 AEs included myalgia (20%), elevated AST (27%) and elevated ALT (53%). One patient in the AC arm died from heart failure with low EF 2 months after having a normal echo 1-3 wk after AC#4. The rate of missing echos was 14%. Of 133 completed echos, 124 (93%) were evaluable for GLS. Mean GLS was <-19% at all times in the simvastatin+AC arm. Mean GLS was <-19% at BL and pre-AC#2 in the AC arm, but ≥-19% at post-AC times in the AC arm. Mean EF was >60% at all times in both arms. Among 27 patients evaluable for the primary endpoint, there was no significant difference in mean |Δ| in GLS from BL to 1-3 wk after AC#4 between the arms (Simvastatin+AC: 0.42%; AC: 1.11%, p=0.57). In addition, there were no differences in the mean|Δ| in GLS from BL to any other time between the arms (all p>0.1). The proportion of patients with GLS<-19% was higher in the simvastatin+AC arm than in the AC arm pre-AC#2 (73% vs 44%), 1-3 wk after AC#4 (67% vs 38%), 24 wk after AC #1 (53% vs 25%) and 52 wk after AC#1 (53% vs 25%) (all p>0.05). The proportion of patients with RelΔ in GLS≥11% from BL was lower in the simvastatin+AC arm than in the AC arm pre-AC#2 (13% vs 19%), 1-3 wk after AC#4 (20% vs 44%) and 24 wk after AC#1(27% vs 31%) (all p>0.05). Conclusion: Simvastatin did not result in a statistically significant difference in the mean |Δ| in GLS from BL to 1-3 wk after AC#4. However, the study was underpowered due to small sample size and there was a suggestion of reduced CT with simvastatin. Co-administration of simvastatin and AC was safe and serial echocardiographic strain monitoring was feasible. Further studies are needed to evaluate the cardioprotective effect of statins on strain in BC patients receiving anthracyclines.
Bone health in young women with breast cancer

Kristen B Wendell¹, Sarah Nadeem¹, Brendan Martin¹, Pauline M Camacho¹, Kathy S Albain¹, Patricia Robinson¹ and Shelly S Lo¹. ¹Loyola University Medical Center, Maywood, IL.

Introduction:
There are limited data and consensus regarding bone mineral density (BMD) monitoring, and management of bone loss in younger women with breast cancer (BC). Adjuvant endocrine therapy for estrogen receptor positive (ER+) BC may include ovarian function suppression (OFS) plus use of aromatase inhibitors (AIs) for 5-10 years, both of which contribute to bone loss. The WHO risk prediction tool FRAX does not include BC or AI use as independent risk factors in its calculation thus underestimating risk of fracture. This study aims to evaluate current screening and management of bone health in young women with BC.

Methods:
A retrospective, IRB-approved chart review was performed in consecutive women ≤40 with BC diagnosed at Loyola University Chicago Medical Center between 01/01/2015 and 12/13/17. Demographic data, BC treatment, and factors contributing to secondary causes of bone loss were collected through 4/1/18. A descriptive analysis included summary values for all categorical and continuous risk factors.

Results:
BC ≤40yrs was identified in 136 women; 18 were excluded due to missing data. The analysis was performed on 118 patients (pts). Mean pt age was 34.6 yrs (SD 4.7). Stage at diagnosis included: stage 0 = 9 (7.6%), stage 1 = 26 (22%), stage 2 = 44 (37.3%), stage 3 = 23 (19.5%), stage 4 = 7 (5.9%), unknown = 9 (7.6%). Seventy-nine (67%) had ER+ BC; 32 (27.1%) had HER2-positive disease. The majority of pts (101, 85.6%) received chemotherapy in their treatment plan. Menopause was documented in 69 (59.0%) pts. Goserelin was used in 31 pts (44.9%), oophorectomy in 17 (24.6%), both in 5 (7.2%). Tamoxifen was used in 44 (55.7%) ER+ pts; 34 (43.0%) received an AI, and 18 (22.8%) received sequential tamoxifen and Al. 25 Hydroxy-Vitamin D (25 OHD) levels were checked in 61 (51.7%); 43 (70.5%) had levels <30 ng/ml; 24 (55.8%) received vitamin (vit) D supplementation. There was no difference in the 25 OHD in pre- and post-menopausal women (p=0.64). Pts with vit D deficiency had a median BMI of 26.8 vs 23.8 in those with sufficient vit D levels (exact p=.049). Secondary diagnoses contributing to low BMD were identified in 14 (11.8%). Dual energy xray absorptiometry (DXA) scans were checked in 23 pts (19.7%), 18 of whom were post-menopausal. At the femur, 0 pts had a z-score (age-matched standard deviation) of ≤-2.0. At the lumbar spine, 1 pt (4.3%) had a z-score ≤-2.0, 9 pts (39.1%) had a z-score between 0 to -2.0. No T-scores were in the osteoporosis range; 11 pts had T-scores at both femur and lumbar spine in the osteopenia range. The median 10 yr probability of a major osteoporotic fracture (FRAX score) was 1.9% (1.6-2.7%); the median 10 yr probability for hip fracture was 0.1% (0.10-0.20%). There were no differences in FRAX scores between pre- and post-menopausal women. No fractures were reported in the time period studied. Anti-resorptive therapy was used only in patients with metastatic bone disease.

Conclusions:
25 OHD and DXA scans are not routinely checked in younger women diagnosed with BC. Vit D deficiency and evidence of bone loss is prevalent in those pts who do undergo testing. Further research and guidelines are necessary to address management of bone health in young women with BC to minimize future fracture risk and morbidity.
A modest proposal for classical massage on chemotherapy-induced peripheral neuropathy in breast cancer patients receiving adjuvant paclitaxel: A randomized controlled trial using electromyography

Umut Demirci², Nur Izgu¹, Zehra Gok Metin¹, Canan Karadas¹, Leyla Ozyemir¹ and Nil Çetin². ¹Hacettepe University Nursing Faculty, Ankara, Samanpazari, Turkey and ²Dr Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, Demetevler, Turkey.

Background: Oncology professionals face challenges to find out a complete solution in prevention or alleviation of chemotherapy induced peripheral neuropathy (CIPN). Current pharmacological treatments used for CIPN have limited effects and pose major side effects. At this point, management of CIPN by a multidisciplinary team approach is very crucial. Therefore, this randomized controlled study aimed to examine the effect of classical massage on CIPN using objective and subjective measurements in breast cancer patients receiving adjuvant paclitaxel.

Method: The study was conducted at Dr. Abdurrahman Yurtaslan Ankara Training and Research Hospital in Turkey between July 2017 and June 2018. The study was approved by a local ethical committee. Eligible patients with breast cancer included those who (a) were 18 years and older; (b) had no documented diagnosis of CIPN; (c) had receiving the first cycle of adjuvant paclitaxel. Exclusion criteria were (a) history of severe psychiatric disorder; (b) history of peripheral neuropathy due to any cause; (c) had lesion on hands or feet; (d) had bleeding or coagulation disorders. Simple randomization method was utilized to allocate patients to an intervention group (n=18) and a control group (n=19). Patients in the intervention group (IG) received totally 12 sessions classical massage, on the days of chemotherapy cycles. The duration of each massage was 30 min, with 20 min for the feet and 10 min for the hands. The CG received only routine care. After completion of paclitaxel regimen no intervention was applied to neither the IG nor the CG, and patients were followed at week 16. Subjective measurement tools included the Self-Leeds Assessment of Neuropathic Symptoms and Sign (S-LANSS); and the European Organization for Research and Treatment of Cancer-Quality of Life Questionnaire Chemotherapy-Induced Peripheral Neuropathy (EORTC QLQ-CIPN20). Electromyography (EMG) was applied as an objective measurement at baseline and week 12 for all patients by the same neurologist. The data were collected at five time points including baseline (T1), week 4 (T2) week 8 (T3), week 12 (T4) and week 16 (T5). To analyze data repeated measures ANOVA and Mann Whitney U tests were used.

Results: The S-LANSS scores were significantly lower in the IG when compared the CG (p<.05). Motor sub-dimension scores of EORTC QLQ-CIPN20 were significantly lower in favor of the IG compared to the CG. As for sensorial and autonomic sub-dimensions of the EORTC QLQ CIPN20 showed no significant difference. Regarding EMG outcomes, compound muscle action potentials of ulnar nerve and posterior tibial nerve in the IG were significantly higher than the CG at week 12.

Conclusion: In this study, classical massage initiated concurrently with adjuvant paclitaxel regimen decreased neuropathic pain severity and prevented motor axonal neuropathy in the IG when compared to the CG. Accordingly, classical massage had promising effects on prevention and alleviation of CIPN. Based on the results, classical massage can be recommended as a preventive complementary option for breast cancer patients receiving adjuvant paclitaxel.
Does initial cardiac imaging impact clinical outcomes in patients with breast cancer?

Sarah Parent1, Lingyu Xu1, Herald Becher1, John Mackey1, Karen King1, Edith Pituskin1 and Ian Paterson1. 1University of Alberta, Edmonton, AB, Canada.

**Background:** Echocardiography (echo) and multigated acquisition (MUGA) scans are the most commonly used modalities to assess cardiac function during breast cancer (BC) treatment. However, a case series of 176 patients with cancer suggests enhanced cardiac care with echo surveillance. We hypothesized that patients with early BC imaged by echo have improved cardiac outcomes compared to those imaged by MUGA.

**Methods:** Consecutive patients with stage I to III breast cancer undergoing pre-treatment echo or MUGA were retrospectively screened from January 2010 to December 2014. Patients participating in clinical trials with mandated imaging and/or cardiac reviews were excluded. Demographics, medical history and clinical events were collected via chart review and electronic health records. All patients had a minimum 1 year of follow-up. The primary outcome was a composite of death, cardiac hospitalization or cardiac emergency room visit.

**Results:** 598 patients were identified as having a baseline echo and 636 had had baseline MUGA. Mean follow-up was 4.5±1.4 years. Patients undergoing MUGA were younger, had more advanced stage of disease and received more anthracycline and trastuzumab (table1). Patients imaged by MUGA had lower cardiac function at baseline compared to echo, LVEF 64% vs. LVEF 65% respectively, P <0.001. Cancer therapy related cardiac dysfunction was similar between groups, 10% vs. 11%, p=0.81. Patients in the echo group were more likely to be seen by cardiology, 7% vs. 3%, p<0.0001, and to be initiated on beta blocker, 4% vs. 1%, p=0.006, or angiotensin converting enzyme inhibitor, 3% vs. 1%, p=0.002.However, there was no difference between groups for the primary outcome, 10% event rate in each group, even after adjustment for age, BC stage, chemotherapy and cardiac medications, hazard ratio 1.04 (CI 0.72-1.49), p=0.842.

**Conclusion:** For patients with early stage BC, the choice of cardiac imaging modality at baseline does not impact adverse cardiac events. However, patients undergoing echo were more likely to be evaluated and managed by cardiology.

Introduction
Recently scalp cooling during chemotherapy infusion has been reported to be quite effective to mitigate chemotherapy-induced alopecia. But data in Asian patients are quite limited.

Patients and methods
Japanese breast cancer female patients who planned to receive (neo)adjuvant chemotherapy were offered to participate in this prospective study of scalp cooling with Paxman Scalp Cooling System for alopecia prevention. The scalp cooling was done 30 minutes prior to and during and 90 minutes after each chemotherapy infusion. Photographs of the head of the participants were taken from 5 directions, namely front, back, both sides, and top, on the day of chemotherapy infusion and 1 month after the last infusion. Two investigators consisting of a physician and a nurse judged the grade of alopecia by looking at the photographs according to the WHO classification. The primary outcomes were the rates of patients with Grade 3 alopecia (defined as hair loss of > 50%) and the rates of patients who used a wig or hat to conceal the hair loss one month after the last infusion of chemotherapy. This paper reports on the former outcome mainly. They were asked to answer a brief questionnaire regarding headache, fatigue, chill etc. shortly after each cooling. They could use the cooling cap for free on the first cycle of chemotherapy. But they were required to purchase it (about 1,130 US$) for the scalp cooling of the following cycles.

Results
One hundred forty three patients participated in the study and actually used the cooling cap at least once. The mean and median age of them are 50.6 and 50, respectively (28 - 76). One hundred twenty nine patients completed the planned chemotherapy of 4 to 8 cycles (89 Pts 4 cycles, 1 Pt 6 cycles, 39 Pts 8 cycles). Among them (7 patients were not evaluable), 74 patients (60.7 %) had Grade 3 alopecia 1 month after chemotherapy. In 80 patients who used the scalp cooling system throughout the planned chemotherapy (1 patient was not evaluable), 36 patients (45.6 %) experienced Grade 3 alopecia. On the other hand, among 49 patients who discontinued the cooling mostly after the 1st cycle (6 were not evaluable), 38 (88.3 %) had Grade 3 alopecia. When we restrict them to 33 (5 were not evaluable) who decided to discontinue the cooling by day10 of the first cycle of chemotherapy to exclude the patients who discontinued it because of less effect on alopecia prevention than they expected, 25 (89.3 %) experienced Grade 3 alopecia. Comparing the results of those who completed the cooling and patients who decided to discontinue it by day10 of the first cycle, the rates of Grade 3 alopecia (45.6 % vs. 89.3 %) were statistically significantly different in favor of the former ($P = 0.0001$). Most patients complained of some headache, chill, and pain of the jaw.

Conclusion
Scalp cooling with Paxman Scalp Cooling System during chemotherapy infusion in Asian women seems as effective for hair loss mitigation as in Caucasian women.
Meta-analysis of Phase I pharmacokinetic/pharmacodynamic results of proposed biosimilar pegfilgrastim

Roumen Nakov¹, Jessie Wang², Yuming Chen², Anne Bellon¹, Sreekanth Gattu¹, Andriy Krendyukov¹ and Yuhan Li². ¹Hexal AG, Holzkirchen, Germany and ²Sandoz Inc., Princeton, NJ.

Background
The long-acting granulocyte colony-stimulating factor (G-CSF) pegfilgrastim is widely used to prevent chemotherapy-induced neutropenia (CIN). Biosimilars could potentially improve sustainability of cancer care. Sandoz proposed biosimilar pegfilgrastim is under development and has been evaluated in Phase I and III studies.¹² The current meta-analysis uses data from two Phase I studies in healthy volunteers (HVs) comparing pharmacokinetic (PK)/pharmacodynamic (PD) properties of Sandoz proposed biosimilar and EU-reference (Neulasta®) pegfilgrastim.

Methods
Data from two studies were included: a single-dose, double-blind, parallel-group study (study 1, data on file) and a single-dose, double-blind, crossover study (study 2),³ both in HVs randomized to receive proposed biosimilar or reference biologic (PK/PD analysis populations: study 1, n=93 per arm; study 2, n=169 per arm). Primary PK and PD parameters were AUC₀–₉₀, AUC₀–last, C_max and ANC AUEC₀–₉₀, ANC E_max, respectively. For each parameter, geometric mean ratios and confidence intervals (CIs) for treatment comparisons (proposed biosimilar vs reference biologic) from the two studies were combined using meta-analytical techniques with a fixed-effects model. The 90% (PK) or 95% (PD) CIs were calculated and PK/PD biosimilarity was demonstrated if all CIs fell within equivalence margins of 80% to 125%. Non-baseline corrected PD parameters were used.

Results
The combined CIs of the geometric mean ratios for primary PK and PD parameters were all contained within the predefined equivalence margins. Safety, tolerability and immunogenicity were found to be similar between proposed biosimilar and EU-reference biologic in HVs (data not shown).

Conclusions

This meta-analysis of two Phase I studies supports PK/PD similarity of Sandoz proposed biosimilar to EU-reference pegfilgrastim. Also, no clinically meaningful differences in safety, tolerability and immunogenicity were found. Sandoz proposed biosimilar pegfilgrastim presents as a sustainable option to manage CIN in patients with cancer.

The effectiveness of breast ultrasonography in cancer screening: A comparison with mammography

SuYeon Jeong¹, YooSeok Kim¹ and KweonCheon Kim¹. ¹Chosun University Hospital, Gwangju, Korea.

Purpose
Mammography (MMG) is a measure of screening that is proven to be effective in lowering death rate in breast cancer validated by randomized control trials. Recently, the number of incidence of breast cancer in Korean women is showing ascending tendency, and also as compared to those in North American and European countries, prevalence age tends to be lower. Since they tend to have much dense breast, MMG alone can hardly be considered as a sufficient measure of breast cancer screening.

The purpose of the study is to study the effectiveness of breast ultrasonography (US) in breast cancer screening in Korean women by investigating the ratio of patients who are diagnosed as malignant in breast US over those who are diagnosed as negative or benign (category 1 and 2) and dense breast (category 0) in MMG.

Materials and Methods
We conducted the retrograde study over 2776 female subjects who had undergone screening MMG in single center in South Korea during the period between Jan, 1st 2010 to Dec, 31st 2016. Female patients are categorized according to BI-RAD category. 164 of subjects were previously undergone a breast cancer surgery, which made them eliminated from the list, and 2612 subjects are finally selected.

Results
Some more 33 subjects are excluded from the list and rest 2579 subject had undergone breast US. Among these, 1133 subjects (43.9%, 1133/2579) correspond to dense breast of BI-RADS category 0, while 303 of them are suspected of category 4 or more.

. The subjects corresponding to category 1 to 3 are 663, 251 and 229 respectively. 307 of 1133 subjects in category 0 are confirmed as having suspicious lesion based on findings of breast US. Among them, 66 subjects are identified as malignant based on biopsy, which accounts for 5.8% (66/1133). 104 subjects in category 1, are confirmed to have lesions based on findings of breast US, where 25 alone were identified as malignant (3.8%, 25/663). Likewise, 10 (4.0%, 10/251) in category 2 and 13 (5.7%, 13/229) in category 3 are identified.

**Conclusion**

It appears that 43.9% of total 2579 subjects undergone MMG and breast US are confirmed as dense breast in category 0 and 5.8% of them are diagnosed as breast cancer according to breast US and biopsy. Likewise, for those who are considered as either category 1 or 2, which is negative or benign lesion category, 3.8% are diagnosed as breast cancer. As it is appeared in this study, cancer detection can be more effective in parallel measure of MMG and breast US rather than MMG alone, especially for breast cancer screening of Korean female subjects.
2018 San Antonio Breast Cancer Symposium®

Glandular dose in contrast-enhanced dual-energy mammography

Elsa Cossu¹, Francesca Castellani¹, Valeria Fiaschetti¹, Mondillo Mariateresa¹, Ranalli Tiziana¹ and Taibi Angelo². ¹Fondazione Policlinico Tor Vergata, Rome, Italy and ²Università degli Studi di Ferrara, Ferrara, Italy.

INTRODUCTION
Estimation of the Average Glandular Dose (AGD) absorbed by the breast during x-ray based examination is an established part of quality control procedures for breast imaging, both for standard mammography and new techniques as digital breast tomosynthesis (DBT) and contrast enhanced digital mammography (CEDM). It is however fundamental that every optimization program obtains an adequate imaging quality. In our study we evaluated the AGD absorbed by the breast, during CEDM examinations, performed with Dual Energy (DE) technique in our Department.

MATERIALS AND METHODS
We retrospectively evaluated 37 DE mammograms; we reported and analyzed AGD, Entrance Skin Exposure (ESE), anode/filter combinations, breast thickness, kV (kilovolt), mAs (milliAmpere per second), and compression in daN (decaNewton) values, for each mammography view obtained on high and low energy. In 10 Patients, it was possible to compare DE with a recent standard mammography performed on the same mammography unit.

RESULTS
AGD values for the entire DE study, in craniocaudal and mediolateral oblique views, resulted between 4.23 mGy and 13.44 mGy; based on the breast thickness (27-79 mm) and on the anode/filter combination. We found out a significantly lower AGD for small breast thicknesses and Mo/Rh and Mo/Cu combination compared to Rh/Rh and Rh/Cu.
In the whole study evaluation, the AGD percentage report due to low and high energy acquisitions resulted between 76.8% and 81.6%, and between 18.4% and 23.2%, respectively.
For the 10 Patients in which was possible a direct comparison with the data obtained with recent standard mammography, resulted a ratio between DE AGD and standard mammography AGD variable from 1.43 to 2.48 (mean value: 2.0), again with lower AGD values obtained with Mo/Rh - Mo/Cu combination and for small breast thicknesses.
AGD ratio between low energy and standard mammography acquisition resulted between 1.23 and 3.31.

DISCUSSION
CEDM is proving to have all the potential to get a definite role in diagnosis and breast tumor staging, providing a direct correlation between morphologic and functional imaging.
In our study we assessed the dosimetry to determine if an additional x-ray exposure will be a limit to DE use and, if that is the case, in which measure. Data in the literature on DE dosimetry are still spare and extremely heterogenous.
In any case, the increase of delivered dose could be justifiable when compared to the great benefits given by this technique in breast cancer early diagnosis and staging, especially in dense breast tissue, in the follow-up of Patients with breast cancer history and in case of MRI incompatibility.
Furthermore, when compared to MRI, CEDM is an easy-access, low-cost, fast and well accepted exam by the patient.

CONCLUSIONS
Although the risk of induced carcinogenesis associated with x-ray breast modalities is small, dosimetric aspects should be considered both for the risk evaluation and for optimization of acquisition systems; with the advance of the technologies we will be able to have a dose reduction by maintaining high quality standards.
Results obtained from this preliminary study needs to be extended by a larger case study to get a complete evaluation and comprehension of the phenomenon.
Comparison of mammography findings between dense and non dense breast in Japanese subjects: The potential limitation of routine mammography

Naoko Takigami¹, Kentaro Tamaki¹,²,³, Yoshihiko Kamada¹, Kano Uehara¹, Shigeharu Terukina¹, Takanori Ishida², Minoru Miyashita², Keely May McNamara³, Nobumitsu Tamaki¹ and Hironobu Sasano³. ¹Nahanishi Clinic, Okinawa, Japan; ²Tohoku University Graduate School of Medicine, Miyagi, Japan and ³Tohoku University Hospital, Miyagi, Japan.

Introduction
Recently “Dense breast” has attracted numerous attention because of diagnostic difficulty in mammography among those harboring dense breast, which is far more frequent in Asian than Caucasian women. Therefore, in this study, we retrospectively evaluated the risks of subsequent development of malignancy through comparing the detailed mammographic characteristics between Japanese subjects harboring dense and non dense breasts.

Methods
We retrospectively examined mammographic findings taken from March 2013 to March 2016 at Nahanishi Clinic, Okinawa, Japan. We stratified its density according to the suggestion of the Japan Central Organization on Quality Assurance of Breast Cancer Screening, which was defined by the proportion of fat area as follows; extremely high dense:10-20%, heterogeneously dense:40-50%, scattered fatty:70-90%, fatty: almost all the breast fat. “Dense breast” includes extremely high and heterogeneous dense. We evaluated the detailed radiological findings of each phenotypes including the characteristics of the mass, calcification and focal asymmetric density(FAD) and architectural distortion. We also compared the rates of subsequent cancer development and sensitivity of detecting cancer between those harboring dense and non dense breasts.

Results
We reviewed the mammography findings of 7747 Japanese women including 857 with breast cancers. When adjusted for age, the rate of dense breast was significantly associated with age, 88.6% in women in their 20s(vs40s p<0.001 OR3.402), with incremental decrease, 80.4% in 30s(P<0.001 OR1.802), 69.5% in 40s, 55.9% in 50s(P<0.001 OR0.512), 32.3% in 60s(P<0.001 OR 0.108), 19.5% in 70s(P<0.001 OR 0.106) and 5.3% in over 80s(P<0.001 OR0.024). The rate of malignancies was 9.1% (385) in dense and 13.6% (472) in non dense breasts. We then compared the mammographic findings between dense and non dense breast. Abnormal calcifications were detected more frequent(7.6%vs5.3% P<0.001 OR1.478) but masses less so(16.4%vs23.7% P<0.001 OR 0.632) in dense breast, while no significant differences detected in FADs(4.9%vs4.6% P=0.35 OR1.074) and distortions(1.2%vs1.4% P=0.29 OR=0.859) between dense and non dense breasts. The rate of carcinoma was less frequent in dense breast among those associated with mammographic calcification(19%vs27.3% P<0.01 OR0.626) but more frequently in dense breast among those with masses (13%vs19% P<0.001 OR0.628). The rate of carcinoma was not different between dense and non dense breast in those with FADs (21.6vs20.6% P=0.72 OR1.067) and distortions(71.7%vs74.7% P=0.64 OR0.857). In addition, among 37 breast cancer patients who did not harbor the mammographic findings above (26 dense and 11 non dense breasts), the average mass length was significantly larger in dense (13.6mm) than non-dense breast (9.9mm) (P=0.018 used Welch’s t test), respectively.

Conclusion
Results of our present study did demonstrate that detection of malignancy in those with mammographic dense breast is more difficult. Therefore, in those harboring dense breast in mammography, addition of other modalities such as US could improve the detection of breast carcinoma.
The relationship of breast density in mammography and magnetic resonance imaging (MRI) in women with triple negative breast cancer (TNBC)

Jennifer Chun¹, Freya Schnabel¹, Jessica Gooch¹, Jiyou Lee¹, Talia Jubas¹, Jenny Goodgal¹, Amber Guth¹ and Linda Moy¹. ¹NYU Langone Health, New York, NY.

Introduction:
TNBC represent 10%–20% of invasive breast cancers. Previous studies showed that TNBC usually present with benign features on mammography, ultrasound and MRI. However, there is a dearth of information on the relationship of mammographic breast density (MBD), background parenchymal enhancement (BPE) and fibroglandular tissue (FGT) on MRI with TNBC. The purpose of this study was to evaluate the relationship between BD, BPE, and FGT in women with TNBC compared to non-TNBC in a contemporary cohort of women with breast cancer.

Methods:
The Institutional Breast Cancer Database was queried for women who had invasive breast cancer and underwent mammography and MRI between (2010-2017). Variables of interest included clinical, pathologic, and imaging characteristics. Statistical analyses included Pearson’s Chi Square and logistic regression.

Results:
Of 2224 women, 210 (9%) had TNBC. The median age was 59 years (22-95) and median follow up was 4 years. When we looked at the clinical characteristics of women with TNBC compared to non-TNBC, race, BRCA1,2 status, method of presentation, palpability, histology, grade, and Ki67 were statistically different (Table 1). When we looked at the correlation of MBD, FGT, and BPE for women with TNBC, MBD was correlated with FGT (r=0.64) but weakly correlated with BPE (r=0.22). We found a significant association of low BPE and TNBC compared to the non-TNBCs (p=0.021) (Table 1). In a short period of time, only 8 women with TNBC had a recurrence with no significant association with MBD, BPE, or FGT (Table 1).

**Conclusions:**

In our study population, MBD and FGT did not differ between patients with TNBC compared to non-TNBC. Interestingly, we found a higher proportion of women with lower BPE in the TNBC compared to the non-TNBC group. BPE refers to the amount of enhancing fibroglandular tissue and has been demonstrated to reflect variations in estrogen-mediated vascular permeability. Lower BPE in TNBC may reflect the fact that these tumors are not hormonally sensitive. This may also have implications for radiogenomics, which aims to correlate imaging characteristics with gene expression and genome-related characteristics in tumor biology. Further studies are warranted in looking at these imaging biomarkers and TNBC.
Improving efficiency of breast MRI utilization by coordinating primary care, breast imaging and surgeons

Cary S Kaufman1,2, Valerie S Behrndt3, Willaim Hall4, Kimberlee Moses5, Greg M Wolgamot6, Lars Crabo3, Laura Backer3, Ken Carpenter3 and Shelly Smits3. 1University of Washington, Bellingham, WA; 2Bellingham Regional Breast Center, Bellingham, WA; 3Mt. Baker Imaging, Bellingham, WA; 4Northwest Radiation Oncology Associates, Bellingham, WA; 5PeaceHealth Cancer Center, Bellingham, WA and 6Northwest Pathology, Bellingham, WA.

Introduction: Breast MRI in the workup of a new breast cancer diagnosis is both a valuable and costly imaging study. The decision to obtain a breast MRI is often made by the surgeon who is referred the newly diagnosed breast cancer patient. That is followed by a delay in their management due to scheduling the MRI. Our breast center program leadership developed a protocol to move the time of MRI prior to the surgeon's evaluation while avoiding unnecessary breast MRIs ordered by some well-intentioned primary care providers. Coordinating a breast MRI protocol can optimize timely performance of breast MRI, guiding primary care to become the ordering clinician while avoiding unnecessary breast MRIs.

Methods: Recognizing a delay in the journey of newly diagnosed breast cancer patients that have their breast MRI ordered only after the multidisciplinary conference or surgical consultation, we developed a protocol to improve timeliness of care. Guidelines were identified by our breast program leadership when a newly diagnosed breast cancer patient would warrant a breast MRI. Agreed upon indicators included dense breast tissue, invasive lobular breast cancer, patients typically under 50 years old, and vague imaging of primary lesions. When these findings were identified, the radiologist included a statement with the core needle biopsy report. It stated that our breast program leadership identified this patient as benefiting from a breast MRI ordered soon after the positive biopsy. This avoided the issue of self-referral since our breast leadership created the guidelines. The message went to the primary care provider who now ordered the breast MRI prior to conference or surgical consultation. We examined sixty consecutive patients from two time periods, half before and half after institution of the MRI protocol.

Results: Prior to this policy, patients who needed breast MRI would obtain the study on average 12 days after our multidisciplinary breast conference (MDC), while after institution of the policy breast MRI was obtained 3 days PRIOR to conference. Before only 43% of necessary breast MRIs were ordered prior to surgical consultation while after the protocol 100% of breast MRIs were ordered PRIOR to surgical consultation. Before the protocol rarely did primary care order breast MRIs. After the protocol primary care providers ordered 80% of all breast MRIs. While ordering more breast MRIs, primary care ordered less unnecessary studies. After the protocol was instituted, inappropriate studies as determined by the MDC decreased from 21% deemed unnecessary to only 10%.

Conclusions: Institution of a breast MRI ordering guideline by the breast program leadership with participation of primary care had the benefits of obtaining the breast MRI before the multidisciplinary conference and/or surgical consultation while avoiding unnecessary breast MRI orders. Institution of a breast MRI protocol enhances patient care, eliminates delays in treatment, avoids unnecessary tests, shifts appropriate care to primary care providers and allows initial surgical consultation to have all the data necessary to make definitive decisions. This quality improvement effort via program leadership improved comprehensive care.
Testing machine learning algorithms' performance for non-invasively identifying breast cancer molecular subtypes using BI-RADS evaluations

Alpay Ozcan¹, Umit Aksoy Ozcan¹, Suheyla Ekemen²,³, Sila Ulus¹ and Basak Oyan¹. ¹Acibadem Mehmet Ali Aydinlar University, Istanbul, Turkey; ²Acibadem Pathology Laboratory, Istanbul, Turkey and ³Halic University, Istanbul, Turkey.

Purpose: Inter- and intra-observer variability adversely affects interpretation of highly advantageous MRI data in breast cancer diagnosis, prognosis and therapeutic decisions. Machine learning (ML) might potentially provide support to the physicians for objective decision strategies. In this work, ML methods using BI-RADS features were tested for non-invasively determining molecular subtypes of breast cancer.

Methods: In this IRB approved study, Out of 126 consecutive patients' retrospective data with written consent, 69 patients (mean±std age 48.24±11.62 and range [27-82]) with full histopathological and MRI data were selected. In surgical histopathological data ER+PR+HER2- was classified as luminal HER2(-), ER+PR+HER+ was classified as luminal HER2(+), ER-PR-HER2+ was classified as HER2(enriched) and ER-PR-HER2- was classified as triple negative. The cohort revealed 51 luminal HER2(-), 11 luminal HER2(+), 7 triple negative cases without any HER2(enriched) occurrence. DCE, DW, T2W MRI data were obtained on a 1.5T Magnetom Espree (Siemens, Erlangen, Germany) scanner which were subsequently interpreted in consensus by 2 radiologists of 15 and 10 years of experience.

Age, mass and non-mass properties, non-enhancing BI-RADS findings, ADC values obtained from radiologist drawn ROIS and kinetic curve properties were fed to 22 standard ML algorithms provided in Matlab® (Mathworks, Natick, MA, USA) as predictors for 3 categories. The algorithms were run by cross validating on 50 folds whereby reported classifier accuracy was obtained from each of the observations when in held-out fold.

Results: Out of 22 ML algorithms tested Support Vector Machine’s Fine Gaussian variant, Ensemble Boosted Trees and Fine K-Nearest Neighbor resulted in 76.8%, 71.0% and 53.6% accuracy with (100%, 18%, 0%), (92%, 9%, 14%) and (67%, 18%, 14%) true positive rates for predicting each histopathological category respectively. Furthermore, PCA based dimension reduction worsened the outcomes indicating high sensitivity to the feature set.

Conclusion: ML algorithms demonstrated potential as a decision support system increasing assessment objectivity with an added non-invasiveness advantage. However, overall algorithm performance indicates further studies with larger cohorts and broader feature are necessary for refinements and improving ML methodology in breast cancer imaging.
Low-dose imaging technique (LITE) MRI: Introduction of a reduced-dosage dynamic contrast enhanced MRI technique in breast imaging

Deepa Sheth¹, Federico Pineda¹, Gregory Karczmar¹ and Hiroyuki Abe¹. ¹University of Chicago Medicine, Chicago.

Methods and Materials: Between October 2017 and April 2018, six patients (age range: 18-60) with a total of eight lesions (lesion size range: 0.5-2.0 cm as measured on ultrasound) with imaging features suggestive of a fibroadenoma were imaged. All lesions were ultimately either biopsy-proven or clinically-confirmed to be benign. Each patient underwent an IRB-approved dynamic contrast-enhanced MRI scan utilizing a novel dual-dose injection protocol. Pre-contrast scans including T2-weighted scans and high temporal resolutions scans were obtained. Next, 15% of the contrast was administered with post-contrast imaging including: standard T1 weighted scans and high temporal resolution scans. Approximately 10 minutes later, 85% of the contrast was administered with repeat post-contrast imaging similar to prior. Two radiologists reviewed the low-dose MR images and high-dose MR images to evaluate for: lesion conspicuity, imaging characteristics and enhancement kinetics.

Results: In all 8 out of 8 lesions, there was concordance between the low-dose MR images and high-dose MR images in terms of lesion conspicuity and imaging characteristics. While the ratio of the contrast doses administered was roughly 0.18, this was not reflected in the ratios of kinetic parameters. The uptake rate ratio (low-to-high dose) was $1.30 \pm 0.39$, upper limit of enhancement had a $0.31 \pm 0.06$ ratio, and $0.35 \pm 0.06$ for initial area under the uptake curve. Rates of initial uptake measured with low-dose MRI were uniformly and significantly greater than rates measured by the high-dose MRI. Lesion time-to-enhancement was similar for both doses, with a ratio of $0.91 \pm 0.06$. Lesion conspicuity was measured as the ratio of the signal increase in the lesion to the signal increase in the surrounding parenchyma. The average lesion conspicuity over the first minute of enhancement had a low-to-high dose ratio of $1.87 \pm 0.99$.

Conclusion: This preliminary study demonstrates that LITE MRI has the potential to be diagnostically equivalent to standard DCE MRI in breast imaging. Low-dose imaging technique (LITE) MRI can be a promising alternative to standard-dose breast MRI, particularly with recent concerns related to gadolinium deposition.
Correlation of proliferation index markers (Ki-76 and PHH3) with breast MRI apparent diffusion coefficient values

Suheyla Ekemen, Alpay Ozcan, Umit Aksoy Ozcan, Sila Ulus and Basak Oyan Uluc. 1Acibadem Pathology Laboratory, Istanbul, Turkey; 2Haliç University, Istanbul, Turkey and 3Acibadem Mehmet Ali Aydinlar University, Istanbul, Turkey.

Objective: In recent literature, increasing number of studies have analyzed associations between the MRI findings and histopathological features of breast cancer. Ki-67 index is an important prognostic factor in breast cancer which provides information about the mitotic activity and the growth rate of the tumor. The proliferation index markers like Ki-67 and PHH3 (Phosphohistone H3) play an important role in decision making in the treatment regimes. PHH3 is a relatively new entity which is specific only to the proliferation giving it a unique characteristic because it is not observed at the interphase. PHH3 provides a more sensitive and accurate mitotic index with less interobserver variability when compared with conventional H&E staining, thus emphasizing its potentially increased value in practice. In this study, our aim is to correlate both proliferation index markers (Ki-67 and PHH3) with breast MRI features in cases of invasive breast carcinoma.

Material and Methods: In this IRB approved study, out of 126 consecutive patients' retrospective data with written consent, 29 patients (mean±std age 48.86±13.10 and range [28-82]) with full apparent diffusion coefficient (ADC), Ki67 and PHH3 data were selected. In all of these surgical specimens, immunohistochemically administered Ki-67 and PHH3 and immunopositive cells in the digital pathology were counted. MRIs were performed in a 1.5T MR unit (MagnetomEspree with Syngo MR B15 software; Siemens, Erlangen, Germany). Images were evaluated by two radiologists in consensus. Mean ADC values were obtained from radiologist drawn ROIs. The results were analyzed with principle component analysis (PCA) and pairwise covariance analysis.

Results: Mean ADC value was (mean±std) 0.92±0.18 with range [0.67-1.3] (10-3mm2/s), mean Ki67 was 18.62±13.32 with range [5-62] (‘%’ for Ki-67) and PHH3 27.17±30.81 with a range [1-111] (‘10HPF’ for PHH3). When PCA was conducted in (ADC, Ki67, PHH3) space, after normalizing each of the variables 45.223% of total variance was explained mainly by the new variable obtained as a linear combination of the normalized values -0.0866*ADC - 0.9879*Ki67 - 0.7910*PHH3, 37.282% by -0.9879*ADC + 0.1545Ki67 -0.0101*PHH3 and 17.494% by 0.1283*ADC + 0.7806*Ki67 - 0.6117*PHH3 respectively. The analysis demonstrates that while Ki67 and PHH3 values explain much of the variance (45.223% + 17.494%) and thereby are highly correlated as expected, ADC on its own determines a significant portion(37.282%) of the data as well. Moreover, pairwise covariance analysis resulted in ADC, Ki67 and PHH variance values of 2.170, 1.528 and 2.197 respectively and, covariances of ADC|Ki67 (-0.1169), ADC|PHH3 (0.2048) and Ki67|PHH (1.31).

Conclusion: Ki-67 and PHH3 both show good correlation in the assessment of proliferative status of breast cancer. However, breast MRI ADC values cannot be reliably used for the prediction of Ki-67 and PHH3 status of the invasive breast tumors. More studies with larger series are needed to assess the potential of breast MRI to serve as a clinical and/or prognostic factor.
High-risk lesions diagnosed at MRI-guided vacuum-assisted breast biopsy: Imaging characteristics, outcome of surgical excision or imaging follow-up

Satoko Okamoto1,2, James D Covelli1, Wendy B DeMartini1, Bruce L Daniel1 and Debra M Ikeda1. 1Stanford University, Stanford, CA and 2St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.

PURPOSE
To evaluate imaging characteristics, outcome of surgical excision or imaging follow-up on high-risk lesions diagnosed at MRI-guided vacuum-assisted breast biopsy (MRI-VAB).

MATERIALS AND METHODS
We retrospectively reviewed 581 lesions, to include benign, high-risk and malignant lesions, undergoing 9-gauge MRI-VAB from January 2015 to April 2018. We collected patient demographics, risk factors and indications, breast MRI BI-RADS descriptors, histopathological diagnosis at MRI-VAB and surgical excision, frequency of upgrade to malignancy and imaging follow-up of high-risk lesions found in this period.

RESULTS
101 patients with 107/581 (18.4% of all lesions) had high risk lesions at MRI-VAB, including atypical ductal hyperplasia (ADH) n=19/107, 17.8%), lobular neoplasia (n=35/107, 32.7) including atypical lobular hyperplasia (ALH), lobular carcinoma in situ (LCIS), ALH plus LCIS, papillary lesions (n=44/107, 41.1%), radial scar/complex sclerosing lesion (RS/CSL)(n=8/107, 7.5%) and flat epithelial atypia (FEA)(n=1/107, 1%). 71/107 (66.4%) high risk lesions were excised. 16/71 (22.5%) were upgraded to malignancy (4 invasive cancer, 12 DCIS). The upgrade rate for ADH and lobular neoplasia was 5 /16 (31.3%) and 8/26 (30.8%) respectively. The upgrade rate for RS/CSL was 1/6 (16.7%). Of the 22 papillary lesions excised, 2 (9.1%) demonstrated pathologic atypia and were upgraded to DCIS. The other 20 papillary lesions had no upgrade or atypia. Excised high risk lesions showing upgrade varied from 0.4 to 6 cm in length (average 2.1 cm). Increasing size correlated with tendency towards increased upgrade to malignancy, but there were no other specific imaging features to predict malignancy upgrade.

CONCLUSION
There were no specific MRI imaging characteristics of high-risk lesions to predict malignancy upgrade. Therefore, surgical excision is recommended for high risk lesions especially ADH or lobular neoplasia. Additionally, non-atypical papillomas did not demonstrate malignancy upgrade in our small study. And further larger studies may demonstrate that these lesions may not need to be surgically excised.
LIN9 regulation of NEK2 underlies taxol resistance in triple-negative breast cancer

Melyssa S Shively¹, Sylvia S Gayle¹, Jennifer M Sahni² and Ruth A Keri¹. ¹Case Western Reserve University, Cleveland, OH and ²New York University School of Medicine, New York, NY.

Currently, there are no targeted strategies to combat triple negative breast cancer, resulting in poor patient survival. TNBC initially respond well to cytotoxic chemotherapies such as paclitaxel, yet resistance and metastatic recurrence are common. Paclitaxel causes defects in mitotic spindle formation and centrosome function, as well as improper chromosome segregation leading to cell death. While being some of the most effective drugs for this disease, taxanes are associated with high toxicity. Thus discovering new therapeutic targets that are selective for TNBC should yield novel approaches for improving patient outcomes. We discovered that LIN9, a transcriptional regulator of mitosis, is overexpressed in 66% of TNBC and associated with poor survival. We further found that both LIN9 mRNA and protein expression are upregulated in paclitaxel-resistant versus sensitive cells and directly correlates with paclitaxel IC₅₀ values across nine breast cancer cell lines. In MDA-MB-231 and MDA-MB-468 cell lines, enforced overexpression of LIN9 increases multi- and micronucleation, indicators of chromosomal instability. Conversely, LIN9 silencing also results in multi- and micronucleation, and supernumerary centrosomes. Most importantly, LIN9 silencing increases sensitivity to paclitaxel in TNBC cells with intrinsic (BT549) or acquired (MDA-MB-231 and MDA-MB-468) resistance. We have previously reported that treating TNBC cells with Bromodomain and ExtraTerminal protein inhibitors (BETi) reduces LIN9 expression, thus we determined if BETi could reverse paclitaxel resistance. Treatment with the BETi, JQ1, and paclitaxel caused a greater induction of apoptosis compared to either drug alone. Dual treatment also resulted in a potentiation of abnormal centrosomes, multinucleation, and micronucleation compared to that caused by either BETi or JQ1 alone. To identify the mechanism(s) by which genetic or therapeutic suppression of LIN9 reverses paclitaxel resistance, we compared the transcriptomes of TNBC cells transiently transfected with non-targeting or LIN9-targeted siRNAs in MDA-MB-231 and HCC70 cell lines. We further narrowed the list of candidate LIN9 targets by identifying genes that were bound by LIN9 in a published ChIP-Seq dataset from HeLa cells whose expression is also correlated with LIN9 expression and associated with reduced breast cancer patient survival. Using this approach, we identified NIMA-related Kinase 2 (NEK2), a serine/threonine kinase required for centrosome separation during mitosis as a potential mediator of the effects of LIN9 suppression. NEK2 is overexpressed in 47% of basal breast cancers and is associated with poor survival. In addition, NEK2 is upregulated in paclitaxel-resistant cells and LIN9 silencing decreases expression of NEK2. Silencing NEK2 expression also restores sensitivity to paclitaxel in resistant cells. Together, these data indicate that increased LIN9 expression in TNBC promotes paclitaxel resistance by contributing to centrosome dysfunction through upregulation of NEK2. They also indicate that targeting LIN9 expression in addition to paclitaxel treatment may be a viable therapeutic approach for TNBC patients.
Pre-clinical investigation of PP2A inhibitor LB-100 in overcoming and preventing lapatinib resistance in HER2-positive breast cancer

Neil Conlon¹, Martina McDermott¹, Brigid Browne¹, Sandra Roche¹, Fiona O'Neill¹, Justine Meiller¹, Alacoque Browne¹, Alex Eustace¹, Denis M Collins¹, Norma O'Donovan¹ and John Crown¹,². ¹National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland and ²St. Vincent's University Hospital, Dublin, Ireland.

Background: HER2-positive breast cancer (BC) accounts for approximately 15% of all BC. HER2-targeted therapies, such as trastuzumab and lapatinib, have significantly improved the outcome for these patients. However, HER2-targeted therapy resistance is a common clinical issue. We have previously shown that protein phosphatase 2A (PP2A) plays a role in mediating acquired lapatinib resistance in HER2-positive BC and that response to lapatinib is enhanced \textit{in vitro} by the lab-grade PP2A inhibitor, okadaic acid. The aim of this study was to examine the \textit{in vitro} and \textit{in vivo} efficacy of LB-100, a PP2A inhibitor that has completed phase I clinical testing (NCT01837667), in models of HER2-positive BC with acquired resistance to lapatinib.

Methods: HER2-positive SKBR3 and HCC1954 BC cell lines were treated with 250 nM or 1 µM lapatinib, respectively, for 6 months to generate lapatinib-resistant SKBR3-L and HCC1954-L cell lines. \textit{In vitro} sensitivity to lapatinib and LB-100 was assessed by 2D acid phosphatase assay. Combination index (CI) values were generated to identify synergistic combinations. Propidium iodide staining was used to determine cell cycle arrest and apoptosis. In order to examine the \textit{in vivo} efficacy of LB-100, HCC1954-L cells were implanted into the mammary fat pad of BALB/c nude mice and treated with vehicle, lapatinib, LB-100, or lapatinib plus LB-100. To examine the prevention of the development of lapatinib resistance, SKBR3 and HCC1954 cells were treated twice weekly with lapatinib, LB-100 or the combination and stained with crystal violet when confluent.

Results: SKBR3-L and HCC1954-L cells were resistant to lapatinib at clinically relevant concentrations (IC₅₀ values = 2.37 ± 0.58 µM and 1.67 ± 0.34 µM). This represents a 46- and 5.2-fold decrease in lapatinib sensitivity. LB-100 had a greater anti-proliferative effect in the lapatinib-resistant SKBR3-L and HCC1954-L cell lines compared to their respective parental cell lines (IC₅₀ values = 2.12 ± 0.2 µM v 5.38 ± 0.6 µM, and 2.31 ± 0.19 µM v 5.32 ± 0.82 µM, respectively). LB-100 overcame lapatinib resistance in both models, as lapatinib plus LB-100 was synergistic in both cell lines (CI values = 0.56 ± 0.13 and 0.68 ±0.26). LB-100 caused cell death through the induction of apoptosis in SKBR3-L (p = 0.019) and HCC1954-L (p = 0.046) and the addition of lapatinib to LB-100 increased apoptotic induction in HCC1954-L cells (p=0.046). Lapatinib plus LB-100 was well tolerated \textit{in vivo}. The HCC1954-L cell line maintained resistance to lapatinib \textit{in vivo} and the combination of lapatinib and LB-100 significantly reduced HCC1954-L tumour volume compared to all other treatment arms (p = 0.0006). Interestingly, \textit{in vitro} short-term resistance assays showed that the addition of LB-100 to lapatinib could also block the emergence of lapatinib resistance in both parental SKBR3 and HCC1954 cell lines.

Conclusions: This study indicates that LB-100 has \textit{in vitro} and \textit{in vivo} efficacy against lapatinib-resistant HER2-positive BC cell line models and justifies further investigation into its potential to circumvent or prevent lapatinib resistance in HER2-positive BC.
Polo-like Kinase 1 (PLK1) inhibition synergizes with docetaxel in basal breast cancer cells

Antonio Giordano¹, Yueying Liu¹, Kent E Armeson¹, Carolyn D Britten¹, Christiana S Kappler¹ and Stephen P Ethier¹. ¹Medical University of South Carolina, Charleston, SC.

Background. Triple negative breast cancer (TNBC) is a heterogeneous disease entity and gene expression analyses have identified molecular subtypes that are refining our understanding of breast cancer biology and enabling development of targeted therapy. The basal-like 2 (BL2) subtype, as described by Lehmann et al, is characterized by overexpression of EGFR, loss of PTEN, and mutations in the TP53 gene and those patients had a 0% pathologic complete response rate following neoadjuvant chemotherapy. Thus, BL2 breast cancers are intrinsically resistant to chemotherapy and patients with this type of breast cancer have a poor overall survival rate. In a recent genome-scale short hairpin RNA (shRNA) screen of breast cancer cells, PLK1 was a frequent and strong hit in the basal-like subtype, inflammatory breast cancer SUM149, indicating its importance for growth and survival of these breast cancer cells. PLK1 regulates progression of cells through the G2 phase of the cell cycle by phosphorylating FOXM1, which then regulates the expression of cyclins and other genes necessary for cells to progress through cell cycle. However, most of the drug companies discontinued clinical development of PLK inhibitors (PLK1i) (e.g. GSK461364 GlaxoSmithKline, Volasertib Boehringer Ingelheim) in solid tumors due to elevate toxicity shown in phase I-II studies.

Methods. We selected GSK461364 as our PLKi for the in vitro experiments. GSK461364 was combined with docetaxel and cisplatin in a set of TNBC cells including SUM149, SUM159, SUM1315, SUM229, DU4475 and the control MCF10A. We performed cell proliferation assays in order to determine the IC25 (Inhibition Concentration of 25%) and IC50 concentration for each drug across the panel of cell lines. We then examined the influence of drugs on the clonogenic potential of the panel of cell lines, alone and in combination. Synergism or antagonism was determined using the Chou-Talalay method, by determining the combination index (CI) at Fa 0.5 (50% of cell death induced by drug treatment). We used FxCycle™ Stain (Invitrogen) for cell cycle analysis, and CD24/CD44 antibodies (BD Pharmingen™) for stem cell marker analysis. All experiments were carried in triplicate.

Results. GSK461364 caused growth inhibition with IC50 varying from 6.1 nmol/L (SUM229) to 56.5 nmol/L (DU4475). In our growth assay, GSK461364 showed synergy with docetaxel in SUM149 (CI 0.70) and SUM159 (CI 0.62), and with cisplatin in SUM149 (CI 0.58), SUM159 (CI 0.85), and SUM229 (CI 0.54). Only GSK461364 in combination with docetaxel decreased the clonogenic potential of SUM149 (p < 0.001, Interaction Test, 0.001). In SUM149 cells, GSK461364 caused mitotic arrest in phase G2-M with the maximum effect 24 hours after administration of the drug. Moreover, when combined with docetaxel, GSK461364 reduced the relative percentage of CD44+/CD24−/dim population of SUM149.

Conclusion. PLKi in combination with chemotherapy shows promising results in a subset of TNBC intrinsically resistant to chemotherapy. GSK461364 significantly decreased the clonogenic potential and stem cell population of SUM149 when combined to docetaxel. In combination with docetaxel, we demonstrated that is possible to lower the dose of PLKi by 5 folds in order to obtain the same activity.
Targeting the tumor microenvironment by CXCR4 inhibition to abrogate trastuzumab resistance in HER2-positive breast cancer

Shuying Liu¹, Shelly M Xie², Gloria Yang-Kolodji³ and Debu Tripathy¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²The University of Texas Southwestern Medical Center, Dallas, TX and ³University of South California, Los Angeles, CA.

Background: Despite the fact that trastuzumab along with other HER2-targeting drugs has significantly improved the survival of patients with HER2 overexpression breast cancers (HER2+BC), resistance to trastuzumab is a clinical challenge in HER2+BC. Discerning actionable mechanisms of resistance to trastuzumab remains an important unmet need. We previously reported dysregulation of CXCR4 involved in trastuzumab resistance, but its causal role and the associated mechanisms remain unknown.

Methods: We established trastuzumab-resistant (TR) human breast cancer HER2+ cell lines by continuously exposing cells to trastuzumab (20 µg/ml) for at least 6 months. CXCR4 expression was assessed in TR cells or parental cells with Western blot. Quantitative densitometric analysis of the density was performed with AlphaView SA software. Relevant cell phenotypes were measured, including mammosphere formation, in vitro antibody-dependent cellular cytotoxicity (ADCC) assay, and cell invasion induced by 10% fetal bovine serum with or without 100 ng/ml stromal cell-derived factor-1α (SDF-1α, CXCL12), the ligand of CXCR4. ANOVA was used to test differences between more than two groups, while the differences between two groups were assessed based on paired t-test.

Results: To better capture the heterogeneity of HER2+BC, we chose two trastuzumab-sensitive cell lines, BT474 (HER2+/HR+) and SKBR3 (HER2+/HR-) and an intrinsically trastuzumab-resistant cell line, HCC1419 (HER2+/HR-). We found much higher CXCR4 expression levels in cells with intrinsically trastuzumab-resistant cells compared to trastuzumab-sensitive cells. Upregulation of CXCR4 expression was found in each of the acquired TR cell lines compared to their parental cells. Dysregulation of CXCR4 significantly enhanced mammosphere formation and cell invasion (P < 0.001, respectively). SDF-1α induced cell invasion and clumping. Down-regulation of CXCR4 with shRNA significantly increased trastuzumab induced antibody-dependent cellular cytotoxicity (2.17 folds of control cells, P < 0.01). Targeting CXCR4 with its approved inhibitor AMD3100 significantly decreased mammosphere formation and invasion of HER2+BC with TR (P < 0.01; P < 0.0001 respectively).

Conclusion: Our results suggest that the SDF-1-CXCR4 axis plays a critical role in resistance to trastuzumab. Targeting CXCR4 signaling may lead to novel combinational therapies to overcome intrinsic or acquired resistance to trastuzumab in advanced HER2+BC, including postulated effects of trastuzumab on signal transduction, differentiation and immune activation.
Model of acquired resistance to the tyrphostin NT157 in hormone receptor-positive breast cancer

Roudy Chiminch Ekyalongo¹, Rewan Abdelwahab¹, Anja Holtz¹, Amin Sabet¹ and Douglas Yee¹. ¹Masonic Cancer Center, University of Minnesota, Minneapolis, MN.

As previously reported, the small-molecule tyrphostin NT157 binds to the type I insulin-like growth factor-1 receptor (IGF-1R) beta subunit (IGF-IRβ) resulting in degradation of the insulin receptor substrate (IRS) adaptor proteins and inhibits growth of tamoxifen sensitive and resistant ER+ breast cancer cells (Yang, Y. et al. Horm Canc, in press). To investigate effects related to long-term NT157 exposure on IGF signaling, we incubated T47D parental cells in increasing concentrations of NT157 for 20 months. This prolonged exposure resulted in resistant cells (T47D-NTR). Monolayer growth assays showed parental cells inhibited at 0.7 µM of NT157 whereas resistant cells were suppressed by 8 µM of NT157. In parental cells, NT157 caused G0-G1 arrest and an increase in the sub-G1 fraction. However, resistant cells did not show these cell cycle changes after exposure to NT157. Furthermore, the antiproliferative effect of prolonged exposure to 96 hours of NT157 was correlated with decreased activation of Akt/S6k signaling axis and reduction of cyclin D1 expression in T47D parental cells. 48 hours treatment with 5 µM of NT157 resulted in a decrease of IGF-IR and insulin receptor (InR) expression level at 33% and 39% respectively, along with the downregulation of the adaptor proteins IRS-1/2 in only the parental cell line. In resistant cells, the NT157 treatment induced minimal IGF-1R suppression and a 21% increase of IR expression. Additionally, the T47D-NTR cells-maintained IRS protein levels at 10 µM. This absence of IRS protein degradation observed in NT157-resistant cells correlated with the continued expression of estrogen receptor-alpha (ERα), suggesting functional changes within IGF and ERα complex. IGF ligands (IGF-1 or IGF-2) and estradiol (E2) stimulated growth in both cell lines. When NT157 was removed from T47D-NTR cells, they were not re-sensitized to NT157 nor were they affected by IGF dependent growth in the re-introduction of NT157. These findings suggest that resistance to NT157 is mediated by the maintained expression of the IRS adaptor proteins. The continued responsiveness to estradiol and IGF ligands could be due to either a decrease in the drug's half-life or possible changes in NT157 binding to the beta subunit of IGF-IR in resistant cells.
Overcoming MEK inhibitor resistance in triple-negative breast cancer by targeting myeloid cell leukemia-1 (MCL1), an anti-apoptotic protein

Maria Gagliardi¹, Gaurav Chauhan¹, Mary Kathryn Pitner¹, Lakesla Iles¹, Yuan Qi¹, Lajos Pusztai², Debu Tripathy¹, Geoffrey Bartholomeusz¹ and Chandra Bartholomeusz¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX and ²Breast Center | Genomics, Genetics, and Epigenetics, Yale Cancer Center, New Haven, CT.

Background: Triple-negative breast cancer (TNBC), which affects over 170 000 women worldwide every year, is considered the most arduous to treat subtype of breast cancer. With no targeted therapy, high rates of drug resistance and rapid metastasis, TNBC carries a poor prognosis. The MEK-ERK-MAPK signaling cascade is known to play a role in numerous cancers. Despite the lack of activating Ras/MAPK mutations in breast cancer, transcriptional signatures of this pathway are prevalent in TNBC. Our previous work showed that TNBC patients with tumors overexpressing ERK2 had a lower overall survival rate than did patients with low-ERK2-expressing tumors. MEK inhibitors selumetinib (AZD6244) and pimasertib (AS703026) are active in preclinical models, but not as single agents in the clinic. Using a synthetic lethal siRNA screen, we identified myeloid cell leukemia-1 (MCL1) as a potential contributor to selumetinib resistance. Mcl-1 is an anti-apoptotic protein that is highly amplified in numerous human cancers. It is associated with cell immortalization, transformation, and chemoresistance. Patients with TNBC tumors expressing high levels of Mcl-1 have lower overall survival and distant-metastasis-free survival rates. We hypothesized that Mcl-1 promotes MEK inhibitor resistance in TNBC.

Methods/Results: To model MEK inhibitor resistance, we established selumetinib- and pimasertib-resistant clones of SUM-149 and MDA-MB-231 TNBC cells by continuous exposure to increasing concentrations of inhibitors over a six month period. We confirmed the onset of MEK resistance by demonstrating that resistant cells, in comparison to the parental cells, exhibited no change in cell proliferation upon treatment with the MEK inhibitors. Resistant cells also displayed more effective cell migration and mammosphere formation than parental cells, suggesting a higher fraction of tumor-initiating cells.

We found Mcl-1 to be highly expressed in 83% (15 of 18) of TNBC cell lines but only 30% (3 of 10) of other breast cancer cell lines. Resistant cells had higher levels of Mcl-1 than did parental cells. To determine whether Mcl-1 is required for MEK sensitivity, we treated parental and resistant cells with either selumetinib or pimasertib together with S63845, a highly specific Mcl-1 inhibitor. The Mcl-1 inhibitor restored MEK sensitivity in both resistant cell lines. After treatment with the Mcl-1 inhibitor, the resistant SUM-149 and MDA-MB-231 cells had similar cell proliferation rates to those of their parental counterparts. Similar studies were done using an siRNA against Mcl-1.

Conclusion: Our data demonstrate that Mcl-1 may promote TNBC resistance to MEK inhibitors and that Mcl-1 is a promising target for combination therapy. We will continue to explore the mechanisms of MEK inhibitor resistance by screening for additional genes/pathways involved. Our long-term goal is to design rational combination approaches to counteract the emergence of resistance by using novel molecularly targeted therapeutics.
TIMP-4 as a biomarker and alternative activator of growth and survival in trastuzumab-resistant cells

Amy L Brady¹, Krista M Isaac², Paige Adams³, Vlasta Zemba-Palko² and U Margaretha Wallon³. ¹Philadelphia College of Osteopathic Medicine, Philadelphia, PA; ²Lankenau Medical Center, Wynnewood, PA and ³Lankenau Institute for Medical Research, Wynnewood, PA.

Background: Within all invasive breast cancers, 20-30% harbor HER2 gene amplification. HER2 activates signaling pathways promoting survival and cell proliferation resulting in an aggressive phenotype. Even with the development of trastuzumab (anti-HER2 therapy) this subtype has one of the worst outcomes of all breast cancers. Primary and acquired resistance to trastuzumab is increasingly recognized as a major obstacle in the clinical management of HER2 disease. Reported mechanisms of resistance involve a truncated HER2 receptor, mutations in the PI3K/AKT pathway, and up-regulation of alternative tyrosine kinase receptors.

In our prospective IRB-approved study of breast cancers, we observed an over-representation of TIMP-4 positive cancers among HER2-positive patients with disease progression while receiving, or shortly after completing, treatment. Secreted TIMP-4 acts through the tetraspanin CD63 on tumor cells to initiate the same signaling pathways as HER2. Based on this observation we hypothesized that TIMP-4 provides an alternative mechanism to promote continued growth and spread of HER2 positive tumors in the presence of anti-HER2 therapy and might be used as a predictive biomarker for treatment resistance.

Methods: Cell culture experiments using human breast cancer cell lines with HER2 amplification, with or without mutations in PIK3CA and PTEN, were used to assess the effects of anti-HER2 treatment on cell growth and downstream signaling pathways. Cells were grown in the presence or absence of human recombinant TIMP-4 and used to determine the effects on growth, AKT/MAPK activation, apoptosis and response to neutralizing antibodies against HER2 alone or in combination with anti-TIMP4 antibody.

Results: Under normal growth conditions, SK-BR-3 cells (HER2 amplified, wild type PI3K and PTEN) demonstrated a significant growth reduction in the presence of anti-HER2, while anti-TIMP4 had no effect. However, in TIMP-4 elevated conditions cells were resistant to anti-HER2 treatment while anti-TIMP4 had a modest effect. Combining the two antibodies reduced the growth significantly. Cells with mutations in either PI3K (MDA-MB-453) or PTEN (ZR-75-1) were insensitive to anti-HER2 treatment under normal growth conditions. In the presence of TIMP-4, cells with PI3K mutation were still insensitive, while cells harboring PTEN mutation responded to anti-HER2 treatment. Cells with either mutation pattern had a modest response to anti-TIMP4 and the combination treatment. Both antibody treatments were associated with reduced activation of growth and survival promoting enzymes as determined by Western blotting.

Conclusions: Elevated TIMP-4 levels could contribute to what clinically appears as resistance to trastuzumab. While regular anti-HER2 treatment caused diminished growth among cells with wild type PI3K and PTEN, the presence of high TIMP-4 levels necessitated treatment with both antibodies for the same growth reduction. Tumor cells insensitive to anti-HER2 treatment due to mutations in growth and survival promoting pathways acquired a modest response when treated with both anti-HER2 and anti-TIMP4 antibodies. We are currently evaluating the possible mechanism for the observed conversion in sensitivity.
Eribulin-induced EpCAM expression provides drug resistance in triple-negative breast cancer cells

Sunao Tanaka¹, Junji Itou¹, Fumiaki Sato¹ and Masakazu Toi¹. ¹Kyoto University, Kyoto, Japan.

Breast cancer is the most common cancer in women in the world. Among breast cancer subtypes, triple-negative breast cancer is aggressive. Because there is no effective therapy for triple-negative breast cancer, development of a novel therapeutic strategy is required.

Eribulin, a derivative of halicondrin B, is an anticancer chemical. Eribulin treatment has been approved in many countries for patients with metastatic or inoperable breast cancer, including triple-negative breast cancer. The known functions of Eribulin are inhibition of microtubule polymerization and induction of the expression of epithelial genes in breast cancer cells. However, the function of Eribulin-induced genes on the therapy for patients with triple-negative breast cancer remains unclear.

EpCAM (Epithelial cell adhesion molecule) is one of epithelial markers and known as a cell-cell adhesion molecule. In addition, EpCAM expression is involved in drug resistance in cancer. We therefore focused on EpCAM expression in Eribulin-treated breast cancer cells.

We used MDA-MB-231 cells that is a commonly used triple-negative breast cancer cell line. We treated cells with 10 nM Eribulin and observed inhibition of cell growth. In the same condition, we found up-regulation of EpCAM expression in both mRNA and protein levels. In mouse xenograft model with MDA-MB-231 cells, EpCAM expression was detected in whole tumor at 96 h after Eribulin administration. We analyzed the effect of other microtubule polymerization inhibitors, nocodazole and colchicine, on EpCAM induction. In the results, there was no up-regulation of EpCAM expression in cells treated with these chemicals, suggesting that EpCAM expression is not induced by inhibition of microtubule polymerization and growth inhibition.

To analyze EpCAM function on Eribulin treatment, we constructed shRNA-mediated EpCAM knockdown system. We introduced EpCAM knockdown in MDA-MB-231 cells and treated with Eribulin. In the results of cell growth assays, the cell number of Eribulin-treated EpCAM-knockdown cells was significantly smaller than that of Eribulin-treated control-shRNA cells, whereas no change was observed between solvent-treated control-shRNA and EpCAM-knockdown groups. In mouse xenograft experiments, EpCAM-knockdown cells showed smaller tumor weights than control-shRNA cells after administration of Eribulin. These results indicate that EpCAM expression provides Eribulin resistance in breast cancer cells.

In conclusion, we found Eribulin-induced EpCAM expression in triple-negative breast cancer cells. The EpCAM expression provides Eribulin resistance both in vitro and in vivo. These suggest that a combination of Eribulin treatment and EpCAM inhibition may improve therapy for breast cancer.
LINC00624 binding with SFPQ/MATR3/NONO protein complexes enhances resistance to neoadjuvant therapy in HER-2 positive breast cancer by inhibiting tumor immune response

Qi Zhang\textsuperscript{1,2}, Bingqiu Xiu\textsuperscript{1,2}, Yayun Chi\textsuperscript{1,2}, Wei-Ru Chi\textsuperscript{1,2} and Jiong Wu\textsuperscript{1,2,3}. \textsuperscript{1}Fudan University Shanghai Cancer Center, Shanghai, China; \textsuperscript{2}Fudan University, Shanghai Medical College, Shanghai, China and \textsuperscript{3}Collaborative Innovation Center for Cancer Medicine, Shanghai, China.

Background
Neoadjuvant chemotherapy (NAC) has been widely used for its ability to downstage breast cancer. With anti-HER2 therapy, around half of the HER2 positive patients achieve pCR after NAC. However, treatment failure is still a concern and leads to a worse prognosis. New biomarkers and biological mechanisms are waiting to be discovered to tackle this problem.

Methods
RNA-Seq was performed to identify differently expressed RNAs between pCR and non-pCR group. The IC\textsubscript{50} value was measured by CCK-8 assay in HER-2 positive cells (SK-BR-3 and JIMT-1). Quantitative RT-PCR (qRT-PCR) was used to detect the expression levels of LINC00624 and its potential target genes. RNA-seq and GSEA analysis was carried out to determine the target pathways regulated by LINC00624.

Results
Core needle biopsy tissue from HER-2 positive patients was collected before NAC. LINC00624 was found to be down regulated in pCR group compared with non-pCR group by RNA-seq. High expression of LINC00624 was associated with poor overall survival in TCGA database and our own patients cohort. Overexpression of LINC00624 promoted cell proliferation and colony-forming ability. Meanwhile, the IC\textsubscript{50} values of Paclitaxel and Trastuzumab in HER-2 positive breast cells were decreased by LINC00624. Via RNA pull-down assay and mass spectrometry, the SFPQ/MATR3/NONO protein complex, which was reported to be associated with the innate immune system, was found to interact with LINC00624. RNA-seq further revealed that several immunological and inflammatory factors, including 'IFN-\textalpha response', 'IFN-\textgamma response' and 'TNF-\textalpha via NF-\kappaB' were suppressed by LINC00624. IFN downstream molecules were inactivated in LINC00624 overexpressing cells following TNF-\textalpha, IFN-\textalpha, IFN-\textbeta and poly (I:C) treatment, which implies the immune inhibition ability of LINC00624.

Conclusion
LINC00624 is associated with resistance to NAC in HER-2 positive breast cancer. It binds with the SFPQ/MATR3/NONO complex and desensitizes cell response to chemotherapy and anti-HER2 agents via suppressing immunological and inflammatory effect. This study suggests that LINC00624 could serve as a biomarker to predict therapy response to NAC in HER-2 positive breast cancer.
Background: Chemotherapeutic resistance leads to high mortality among triple negative breast cancer (TNBC) and underlying mechanisms are poorly understood. Exosomes have been new member of liquid biopsy. MicroRNAs (miRNAs), as the most important inclusions in exosomes, making them ideal candidate biomarkers and therapeutical targets.

Methods: We isolated exosomes and analyzed exosome-carried miRNAs signatures in several TNBC cells lines sensitive or resistant to adriamycin, docetaxel or cisplatin. The resistance transfer capacity was determined by flow cytometry after sensitive cells incubated 48 hours with exosomes from drug resistant cells. Locked nucleic acid probes and enzyme-labeled fluorescence (LNA-ELF-FISH) was performed to detect exosomal miRNA molecules transfer. Animal mode was constructed to evaluate treatment feasibility using miRNA modified exosomes. Serum exosomes from 40 TNBC stage IV patients underwent chemotherapy before or after progress disease (PD) status were isolated to analyze miRNA profiling for potential biomarkers identification.

Results: We successfully isolated and identified exosomes from several drug sensitive and resistant TNBC cell lines and patients. Exosomal miR-222, miR-4443, miR-100, miR-17, miR-210 were found significantly upregulated from chemotherapy resistance cells. Incubation of exosomes from the resistant cells with the sensitive cells resulted in increasing resistant capacity among sensitive cells. Exosomal miRNA molecules transfer were detected using LNA-ELF-FISH. Transfection of synthesized miRNAs competitors into exosomes increased drug sensitivity in vivo. Exosomal miR-222, miR-4443, miR-100, miR-17, miR-210 were also found upregulated significantly from serums of patients after PD status. These five miRNAs were able to differentiate patients with PD status from those with CR or PR status with at least 89% accuracy.

Conclusion: Exosomes from chemotherapy resistant TNBC cells could transfer drug resistance to sensitive cells via exosomal miRNAs. A circulating exosomal microRNA profiling was established for potential biomarkers and therapeutical targets identification.
Sensitivity to cell cycle inhibitors in taxane resistant breast cancer models

Karen J Taylor¹, Nicola Lyttle², Linda Liao², Charlie Gourley¹, David A Cameron¹, John MS Bartlett¹,²,³ and Melanie Spears²,³.

¹University of Edinburgh, Cancer Research UK Edinburgh Centre, Western General Hospital, Edinburgh, United Kingdom; ²Ontario Institute for Cancer Research, MaRS Centre, Toronto, ON, Canada and ³University of Toronto, Toronto, ON, Canada.

Background: The use of anthracycline and taxane chemotherapy has improved overall and disease-free survival in breast cancer. However these agents have significant toxicity. In addition, breast cancers can acquire or possess intrinsic chemoresistance. It is imperative to identify patients who will benefit most from adjuvant taxane treatment and those with resistant tumours who could be spared unnecessary toxicity.

Methods: A panel of in vitro derived cell lines models of taxane resistance were generated by serial culture in escalating doses of either paclitaxel or docetaxel until resistance was achieved. Taxane resistant cells were characterised by 2D growth, cell cycle and apoptosis analyses. Genomic profiling using the NanoString® platform was performed to identify differentially expressed genes. The identification of kinases which target the chemoresistant models was achieved through a small molecule kinase inhibitor screen. Effects of selected target kinases on cell proliferation, cell cycle, apoptosis and protein expression were assessed.

Results:
Resistant cell lines exhibited an IC50 at least 40-fold higher than that of the parental cells and displayed cross-resistance to the non-establishing taxane.

Dinaciclib, a CDK inhibitor of CDK1, CDK2, CDK5 and CDK9, inhibited taxane resistant cell growth with IC50s comparable to the parental lines. Upon exposure to dinaciclib, cell cycle arrest at G2/M was induced and marked apoptosis demonstrated. A reduction in cyclin B1, PLK1 and pRB was observed by western blotting.

**Conclusion:** In this study we identified candidate resistance-associated pathways which were differentially expressed between *in vitro* derived taxane resistant cell line models and the sensitive parental line. The CDK inhibitor, dinaciclib, demonstrated potent activity against the taxane resistant cell line models. Clinical validation to ascertain the role of dinaciclib as a novel therapeutic in the treatment of chemorefractory breast cancer is required.
Signature-guided biomarker discovery and therapy for trastuzumab-resistant HER2-positive breast cancer

Jun Yin¹, Andrea Sand¹, Chaoyang Sun², Mitchell Piacsek¹,³, Amy Beres¹ and Judy A Tjoe¹,⁴. ¹Aurora Research Institute, Milwaukee, WI; ²MD Anderson Cancer Center, Houston, TX; ³Marquette University, Milwaukee, WI and ⁴Aurora Health Care, Milwaukee, WI.

Background/Objective:
Breast carcinomas with HER2 receptor amplification and overexpression account for approximately 20% of all breast cancers, which also confer more aggressive phenotypes and are associated with poor prognosis. Up to 23% of patients with early-stage HER2-positive (HER2+) breast cancer treated with adjuvant chemotherapy and trastuzumab experience disease recurrence within 10 years, highlighting the importance of identifying which HER2+ patients respond to this treatment and those that do not. Efforts to identify biomarkers predictive of response in the initial breast tumor biopsy to trastuzumab have been complicated by the clinical and biological heterogeneity of HER2+ tumors. Therefore, we aim to develop a trastuzumab-resistant (TRR) signature which could faithfully predict patients' response to this treatment using transcriptome profiles in engineered cell line models. We further investigated the possible mechanisms mediating TRR by bioinformatics and biochemical approaches in order to reveal promising new therapeutic targets TRR HER2+ patients.

Methods:
Publically available transcriptome profile (GSE15043) of genetically engineered isogenic models of TRR cell lineages in mammary HER2+ BT474 cells (initially trastuzumab sensitive, TRS) are used to generate the TRR signature using Bioconductor in R. Performance of this gene signature was tested on independent in vitro and in vivo transcriptome datasets using Receiving Operation Curve (ROC). Signature scores were determined by calculating the correlations between medium centered gene expression levels within the signature and gene expression levels for that gene within a given sample, following quantile normalization. Three pairs of TRR vs. TRS cell lines were used for accessing their profiles of proliferation, migration, genomic stability and signature scores. Genes of interest in the signature were further perturbed in TRR cells for drug sensitivity assay.

Results and Conclusion:
TRR cell lines have significant more malignant phenotypes in comparison to TRS cell lines, indicated by their shorter doubling time, faster migration and more innate double strain breaks. 43 differentially regulated genes between BT474R (engineered TRR cell line) and BT474 are identified and the area under the curve (AUC) of ROCs are 0.75, 0.88, and 0.84 for microarray data of CCLE, RNA sequencing data of CCLE and patient dataset GSE62327, respectively. In addition, TRR signature is significantly enriched in non-responding cell lines, TRR patients and patients relapsed within 3 years after treatment. TRR cell lines – BT474-C5, T47D and HCC1954 exhibit significant higher TRR signature scores in comparison to TRS cell lines by the 43-gene PCR array. Interestingly, overexpression of one of gene candidates, S100A8, which is also a key cytokine in regulating antibody-dependent cytotoxicity (ADCC), conferred trastuzumab resistance in TRR cell lines. This finding could assist in clinicians' diagnosis and selection of treatments for HER2+ breast cancer with a more accurate risk evaluation and offering promising alternatives such as immunotherapy.
ERVMER34 sensitizes the response of HER2 positive breast cancer to neoadjuvant therapy

Yayun Chi¹, Weiru Ji¹, Bingqiu Xiu¹, Qi Zhang¹ and Jiong Wu¹. ¹Fudan University Shanghai Cancer Center, Shanghai, China.

Although anti-HER2/neu antibody therapy combined with chemotherapy has achieved an outstanding effect, many patients with HER2-positive breast cancer still succumb due to therapeutic resistance. Understanding the mechanisms of therapeutic resistance is of vital importance. In this study, core needle biopsy tissue from HER2-positive patients was collected before neoadjuvant chemotherapy. Differentially expressed RNAs between pCR and non-pCR group have been identified through RNA-seq. Here we found that ERVMER34, an endogenous retroviral envelope protein was significantly inhibited in non-pCR group compared to pCR group. High ERVMER34 expression was associated with good overall survival both in TCGA database and our own patients cohort. Further study showed that ERVMER34 could be glycosylated and secreted to cell supernatant. The IC50 of paclitaxel and trastuzumab in HER2 positive breast cancer cells was decreased by ectopic overexpression of ERVMER34. Furthermore, RNA-seq, FACS assay and western blot revealed that ERVMER34 could promote cell apoptosis and sensitize therapy response through inhibiting mTOR pathway in HER2 positive breast cancer cells. Via mass spectrometry, TRIM21, an E3 ligase was found to interact with ERVMER34 and promoted its ubiquitination degradation. Taken together, these data suggest that ERVMER34 may severve as a novel biomarker to predict therapy response in HER2 positive breast cancer.
Exosome mediated breast cancer drug resistance: Delivery of Hsp70 and related mechanisms

Zhi Xu¹ and Jinhai Tang¹. ¹The First Affiliated Hospital with Nanjing Medical University, Nanjing, China.

Background
Adriamycin is widely used in postoperative adjuvant chemotherapy for breast cancer. Although the majority of patients were responsive to the initial treatment for certain time, the patients eventually developed more aggressive tumor forms that were generally resistant to the chemotherapy. Exosomes shuttle bioactive molecules and lead to the exchange of genetic information and metabolic reprogramming of the recipient cells, resulting in transmitting drug resistance. However, the specific mechanism of breast cancer cell derived exosomes mediating drug resistance remains obscure.

Methods
The exosomes derived by MCF-7 resistant cells (A/exo) were co-cultured with sensitive MCF-7 cells and were extracted from the supernatant of cell culture and the exosomal Hsp70 was analyzed. Fluorescence labeled A/exo and Hsp70 were used to observe an increase of Hsp70 fluorescence signal after co-incubation. Meanwhile, the cellular glycolysis level and oxidative phosphorylation level were observed by Seahorse XF analyzer. In addition, we measured the cellular activity of lactate dehydrogenase (LDH) and phosphofructokinase (PFK).

Results
Co-incubation MCF-7 cell with Adriamycin-resistant in MCF-7 derived exosomes (A/exo) was found to enhance Adriamycin resistance in MCF-7. Exosomes were extracted from the supernatant of cell culture and the exosomal Hsp70 was analyzed. Fluorescence labeled A/exo and Hsp70 were used to observe an increase of Hsp70 fluorescence signal after co-incubation, demonstrating that transferring Hsp70 may be one of the mechanisms that A/exo mediates drug resistance. Seahorse XF Analyzer has been used to measure glycolysis and mitochondria oxidative phosphorylation, the results exhibit an increase in glycolysis but a decrease in oxidative phosphorylation in Adriamycin-resistant MCF-7 (MCF-7/Adr) when compared to sensitive MCF-7. While glycolysis level significantly decreased and oxidative phosphorylation level increased after knockout Hsp70 in MCF-7/Adr. Furthermore, we measure activities of lactate dehydrogenase (LDH) and phosphofructokinase (PFK), the results showed that Hsp70 could promote activities of those two glycolysis key enzymes. The results indicated that glycolysis levels in MCF-7/Adr are higher than those in sensitive cells, and mitochondrial damage and increased activity of glycolysis key enzymes may account for this.

Conclusions
Our results demonstrate that Adriamycin-resistant MCF-7 derived exosomes induce a drug-resistant phenotype in sensitive cells through Hsp70 transfer. Hsp70 could promote Adriamycin resistance in breast cancer through regulating PFK and LDH activities and inducing glycolysis.
Mechanism of activation of PPP1R1B drug-resistance gene in trastuzumab-resistant Her2+ breast cancer

Jamil Momand1, Rabi Murad2, Xinyi Ma2, Shuhui Geng1 and Ali Mortazavi2. 1California State University Los Angeles, Los Angeles, CA and 2University of California Irvine, Irvine, CA.

Trastuzumab (Herceptin) resistance is a persistent challenge in the treatment of metastatic Her2+ breast cancer, with an average relapse time of 1 year after treatment. Human breast cancer cell-lines (SKBr3 and BT474) selected for trastuzumab resistance have a PPP1R1B gene (chr17:39,626,924-39,636,626) that is transcriptionally activated compared to their drug-sensitive counterparts. PPP1R1B codes for two related protein products, Darpp-32 (long) and t-Darpp (short), that are overexpressed in 50% of clinical breast cancer samples in comparison to normal breast tissue; reintroduction of t-Darpp into drug-sensitive cells confers drug resistance. The mechanism controlling overexpression of these transcripts is unknown. To gain insight into this mechanism we used ATAC-seq to map open chromatin areas in trastuzumab-resistant breast cancer cell lines and compared their open chromatin areas to those in the parental trastuzumab-sensitive counterparts. The PPP1R1B gene consists of 7 canonical exons. In each trastuzumab-resistant line there is two significantly increased open chromatin peaks, one within exon 2 and one within exon 3. We are performing deep sequencing (>200 million reads) to identify transcription factor footprints in these peaks. Furthermore, we performed RNA-seq analysis and identified genes that are similarly regulated in the resistant lines in comparison to their drug-sensitive counterparts. In summary, these results shed light on an area of high clinical importance and point to potential drug targets to be developed to overcome trastuzumab resistance in Her2+ breast cancer.
KCNN4 confers multiple chemoresistance in breast cancer

Xin Hu¹ and Chuan-Gui Song². ¹Fudan University Shanghai Cancer Center, Shanghai, China and ²Fujian Medical University, Fuzhou, China.

Multiple chemoresistance is a major unmet clinical obstacle in breast cancer treatment. Here, we uncovered that calcium-activated channel subfamily N member 4 (KCNN4) was an important modulator that limit the cytotoxicity of gemcitabine via a pooled ORF library screen. Importantly, elevating KCNN4 expression enhances the multiple resistance to anti-metabolism chemotherapy drugs, and accelerates cell proliferation. Conversely, silencing or using specific inhibitor, TRAM-34, can counteract its multiple chemoresistance and cell proliferative effects. Mechanically, we found that KCNN4 up-regulated BCL2A1 to suppress cell apoptosis progression via activating RAS-MAPK and PI3K-AKT signaling. In clinical specimens of breast cancer, KCNN4 expression was frequently upregulated and positively correlated with BCL2A1 expression. Moreover, high expression of KCNN4 and BCL2A1 was associated with shorten disease-free survival in studied cohorts. Collectively, our findings showed that KCNN4 was a key modulator in breast tumor progression, implicating that targeting the KCNN4 may serve as a promising therapeutic strategy to overcome multiple chemoresistance in breast cancer.
Sabutoclax, pan-active BCL-2 protein family antagonist, eliminates cancer stem cells through inhibiting PI3K/Akt pathway in breast cancer

Jin Zhang1. 1China Tianjin Breast Cancer Prevention, Treatment and Research Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center of Cancer, Tianjin, Tianjin, China.

Introduction/Purpose: Misregulation of BCL-2 family of proteins renders a survival signal to withstand cytotoxic anticancer drugs and is often found in drug resistant cells. The drug resistance phenotype often accompanies activation of the phosphatidylinositol 3-kinase (PI3K)/AKT pathway, as well as an enhancement of cancer stem cell-like (CSC) characteristics. Thus, inhibition of anti-apoptotic BCL-2 family proteins has been proposed as a possible antineoplastic strategy. However, the effects of BCL-2 inhibitors on drug resistant breast cancer have not yet been elucidated. In the present study, the effect of sabutoclax, a pan-active BCL-2 protein family antagonist, on two chemoresistant breast cancer cell lines was assessed.

Methods: MTT assays and drug resistance clonogenic assays were performed to evaluate the cell viability in response to drug treatments. Apoptosis was determined by flow cytometry after annexin V staining, by caspase 3/7 and caspase 9 activity assays and the levels of a series of apoptosis-related proteins by real-time PCR and western blot. The expression levels of AKT and pAKT were assessed by western blot to exam the effect of sabutoclax on the activity of PI3K/AKT pathway. The expression of breast cancer stem cells (BCSC) related markers (CD44, CD24 and ALDH1) were detected by flow cytometry. Mammosphere formation assays and soft agar colony formation assay were performed to test the effect of sabutoclax on the proportion of stem-like cell population. To validate the results showed in breast cancer cell lines, we also tested the ex vivo effect of sabutoclax on nine fresh human breast tumor samples by IHC. The effect of sabutoclax on tumor growth was also studied in mouse xenografts.

Results: We found that sabutoclax showed a significant cytotoxic activity on chemoresistant breast cancer cells both in vitro and in vivo. When chemotherapeutic agents were combined with sabutoclax, strong synergistic antiproliferative effects were observed. Inhibition of BCL-2, MCL-1 and BCL-XL leads to caspase-3/7 and caspase-9 activation, sabutoclax modulated Bax, Bim, PUMA and survivin expression. Furthermore, sabutoclax effectively eliminated the CSC subpopulation and reduced sphere formation of drug-resistant cells through down-regulation of the PI3K/AKT signaling pathway. A similar effect was observed in a panel of nine breast tumors ex vivo.

Conclusions: Our findings indicate that sabutoclax partially overcomes drug resistance of breast cancer cells by reactivation of apoptosis, mediates by the inhibition of several anti-apoptotic BCL-2 family proteins such as BCL-2, MCL-1, BCL-XL and BFL-1, and, by abolition of PI3K/AKT pathway and crosstalk between AKT and BCL-2 family proteins is indispensable for maintaining stemness and chemoresistance in BCSCs. This suggests a strong rationale to explore the therapeutic strategy of using sabutoclax alone or in combination for chemotherapy-nonresponsive breast cancer patients.
Functional and therapeutic significance of *ESR1* fusions in metastatic ER+ breast cancer

Jonathan T Lei¹, Xuxu Gou¹, Sinem Seker¹, Svasti Haricharan¹, Adrian V Lee², Dan R Robinson³ and Matthew J Ellis¹. ¹Baylor College of Medicine, Houston, TX; ²University of Pittsburgh, Pittsburgh and ³University of Michigan, Ann Arbor.

**Background.** Next-generation sequencing methods have identified several *ESR1* fusion genes in treatment refractory ER+ breast cancer, however detailed functional studies in experimental models are lacking and how they might be targeted remains poorly understood. We recently reported two transcriptionally active, in-frame *ESR1* fusions, ESR1-YAP1 and ESR1-PCDH11X, identified in a small cohort of metastatic ER+ cases, that induce not only pan-endocrine therapy resistance but also metastatic disease progression (Lei et al., Cell Reports, *in press*). Limited characterization of ESR1-DAB2 and ESR1-GYG1, also identified in metastatic ER+ disease from a recent study, suggests these two *ESR1* fusions also drive estrogen-independent gene activation (Hartmaier et al., *Annals of Oncology*, 2018). Here, we functionally characterize ESR1-DAB2 and ESR1-GYG1 along with additional *ESR1* fusions discovered in metastatic ER+ breast tumors to further support a causal role for in-frame *ESR1* fusions in driving endocrine therapy resistance and promoting metastasis-associated biology, and explore therapeutic vulnerabilities induced by *ESR1* fusion gene formation.

**Methods.** RNA-seq identified *ESR1* fusions from treatment refractory, ER+ metastatic breast tumors. In-frame *ESR1* fusions constructs were generated and stably expressed in ER+ breast cancer cell lines: T47D, MCF7, and ZR75-1. Estrogen-independent and fulvestrant-resistant growth was monitored in hormone-deprived stable cell lines. mRNA-qPCR was performed to examine expression of estrogen responsive and epithelial-to-mesenchymal transition (EMT) genes. *In vitro* sensitivity to CDK4/6 inhibition was tested with palbociclib and abemaciclib.

**Results.** In addition to previously described ESR1-YAP1, ESR1-PCDH11X, ESR1-DAB2, and ESR1-GYG1, that follow a pattern retaining the first 6 exons of *ESR1* (ESR1-e6) fused in-frame to C-terminal sequences provided by the partner gene, additional in-frame ESR1-e6 fusions, ESR1-PCMT1, ESR1-ARNT2, and ESR1-ARID1B, all identified in metastatic ER+ samples, were found to follow the same fusion pattern. ESR1-DAB2 and ESR1-GYG1 produced stable *ESR1* fusion proteins in ER+ breast cancer cell lines. In T47D, these two fusions drove estrogen-independent and fulvestrant-resistant growth. In addition, T47D and ZR75-1 models revealed that ESR1-DAB2 drove estrogen-independent expression of estrogen responsive genes and also EMT genes, including *SNAI1*, suggesting this fusion, like ESR1-YAP1 and ESR1-PCDH11X, could also drive metastasis. Treatment with CDK4/6 inhibitors suppressed growth induced by ESR1-DAB2 and ESR1-GYG1.

**Conclusion.** The majority of in-frame *ESR1* exon 6 fusions found in metastatic ER+ breast are transcriptionally active, drive endocrine therapy resistant proliferation, and induce an EMT-like transcriptional program. The ability to block *ESR1* fusion induced growth with a CDK4/6 inhibitor is clinically significant as *ESR1* fusion gene formation renders ER insensitive to all endocrine therapies that target the ligand binding domain. Furthermore, clinical diagnosis of an active *ESR1* fusion could potentially stratify patients for CDK4/6 inhibitor treatment. This presentation is the most complete description of the role for *ESR1* fusions in endocrine therapy resistance and metastasis described to date.
Progesterone receptor (PR) antagonism by telapristone acetate (TPA): A randomized, placebo-controlled phase IIB pre-surgical window trial in women with stage 0-II breast cancer

Oukseub Lee¹, Megan E Sullivan², Yanfei Xu¹, Ali Shidfar¹, David Ivancic¹, Zexian Zeng¹, Hari Singhal¹, Irene Helenowski¹, Borko Jovanovic¹, Nora Hansen¹, Kevin Bethke¹, Peter Gann³, William J Gradishar¹, Susan E Clare¹ and Seema A Khan¹. ¹Northwestern University, Chicago, IL; ²Northshore Hospital, Evanston, IL and ³University Illinois at Chicago, Chicago, IL.

Background: In vitro and preclinical data indicate that TPA, a selective PR modulator, has activity against hormone-sensitive early breast cancer. We conducted a pre-surgical window trial of oral TPA in Stage 0-II breast cancer to assess the effect of TPA on suppression of cell proliferation (Ki67), and on differential gene expression in responsive and non-responsive tumors.

Methods: We enrolled 70 pre and postmenopausal women into a 1:1 randomized, double-blind, placebo-controlled trial of oral TPA 12mg (Repros Therapeutics Inc.) for 2-10 weeks. The primary endpoint was Ki67 labelling, comparing diagnostic core needle biopsy to post-therapy surgical specimens. Ki67 changes were quantitated by dual immunohistochemistry (Ki67/pan-cytokeratin) and image analysis (Aperio ImageScope and Definiens Tissue Studio®). RNA-sequencing (using RNA extracted from the paraffin blocks) was performed with Illumina TruSeq RNA Coding Access method. Differential gene expression pre-post therapy was assessed, followed by Gene Set Enrichment Analysis for pathway analysis. Ki67 changes from baseline were tested with Paired signed-rank test. For gene expression analysis, p values were calculated by Wald test and adjusted for multiple comparisons by Benjamini-Hochberg method (adjusted p <0.05 and 2-fold gene expression cut-off).

Results: Among 61 evaluable women, (29 placebo and 32 TPA) 97% of tumors were ER or PR positive and 91% were ER and PR positive (balanced across arms). A significant 6% decrease in mean %Ki67 was seen in the TPA arm (p= 0.003). When stratified by menopause, the significance held in premenopausal women (n= 22, p= 0.03) but not in postmenopausal women (n=10, p= 0.08). However, a Ki67 decrease (4%) was also observed in placebo group (p = 0.04); this was non-significant after pre- postmenopausal stratification. Overall, differential gene expression analysis showed no significant modulation of genes in either group. Using a pre-specified response parameter (50% relative reduction in Ki67), we identified 12/32 (38%) “responders” in the TPA, and 9/29 (31%) in the placebo arm. In sub-group analysis of these responders, we found 103 genes to be significantly modulated by treatment in the TPA “responders”, but saw no significant change in any gene expression in placebo “responders”. Gene set enrichment analysis for the 103 genes showed that TPA blocked the progression of cell cycle genes (PTTG1, PLK1,UBE2C, HIST1H3F, PSMD3, and etc.) and suppressed PGR and ERBB2 expression. In a pre-planned pooled analysis, these results will be combined with NCT02314156, reported in SABCS abstract 851790.

Conclusions: An anti-proliferative (Ki67) signal of TPA was observed in early stage breast cancer patients, but interpretation was limited by placebo group changes. The TPA group demonstrated differential suppression of proliferation-related genes among Ki67 responders, but the placebo group did not. Ongoing analysis will examine signatures related to stemness, metastasis, and immune suppression (potentially better endpoints in trials targeting P signaling). These analyses may help us select the right population and the right biomarkers for future trials.
Molecular characterisation of ER+ breast cancer dormancy and acquired resistance using a clinical model: Potential involvement of epigenetic regulation

Cigdem Selli1,3, Arran K Turnbull1,2, Dominic Pearce1, Anu Fernando2, Lorna Renshaw2, Jeremy S Thomas2, Mike J Dixon2 and Andrew H Sims1. 1Applied Bioinformatics of Cancer, Edinburgh Cancer Research Centre, The University of Edinburgh, Edinburgh, United Kingdom; 2Edinburgh Breast Unit, Western General Hospital, The University of Edinburgh, Edinburgh, United Kingdom and 3Faculty of Pharmacy, Ege University, Izmir, Turkey.

Background: The risk of recurrence for oestrogen receptor positive (ER+) breast cancer patients treated with 5 years of adjuvant endocrine therapy persists for many years or even decades following surgery and apparently successful adjuvant therapy. This period of dormancy and acquired resistance is inherently difficult to investigate. Therefore, previous efforts have been limited to in vitro or in vivo approaches. In this study sequential tumour samples from patients receiving extended neoadjuvant endocrine treatment were characterised as a novel clinical model of ER+ breast cancer dormancy and acquired resistance.

Methods: Consecutive tumour samples from 62 patients undergoing extended (4-45 months) neoadjuvant letrozole therapy were subjected to transcriptomic and proteomic analysis, representing pre- (before treatment), early-on (13-120 days) and long-term (>120 days) neoadjuvant letrozole treatment. Patients with at least a 40% initial reduction in tumour size by 4 months of treatment were included. Of these, 42 patients with no subsequent progression were classified as “dormant”, and the remaining 20 patients as “acquired resistant”. Expression analysis was performed by using Illumina BeadChips. R and BioConductor packages were used for analysis. Differentially expressed genes were determined by using paired Rank Products (FDR, 5%).

Results: Multidimensional scaling using most variant 500 genes demonstrated that long-term treated dormant samples clustered separately from their matched pre- and early-on samples whereas long-term treated resistant samples were indistinguishable from their pre-treatment counterparts. Therapy-induced changes in resistant tumours were common features of treatment, rather than being specific to resistant phenotype. Comparative analysis of long-term treated dormant and resistant tumours highlighted changes in epigenetics pathways including DNA methylation and histone acetylation. DNA methylation marks 5-methylcytosine and 5-hydroxymethylcytosine were significantly reduced in resistant tumours compared to dormant tissues after extended letrozole treatment. Decrease in 5-hydroxymethylcytosine were significant early-on.

Conclusions: This is the first patient-matched gene expression study investigating long-term aromatase inhibitor-induced dormancy and acquired resistance in breast cancer. Dormant tumors exhibit distinct molecular changes under extended treatment whereas acquired resistant tumors are more similar to matched diagnostic samples supporting the molecular concordance between primary tumors and metastases. Global loss of DNA methylation was observed in resistant tumours under extended treatment which can be predicted within first 4 months of therapy. Epigenetic alterations may lead to escape from dormancy and drive acquired resistance in a subset of patients supporting a potential role for therapy targeted at these epigenetic alterations in the management of endocrine resistant breast cancer.

Glucocorticoid receptor activation inhibits proliferation of endoxifen resistant breast cancer cells and resensitizes cells to hormonal therapy

Calley J Jones¹, Matthew P Goetz¹, James N Ingle¹ and John R Hawse¹. ¹Mayo Clinic, Rochester, MN.

Background: Despite the prevalent treatment options for ERα-positive breast cancer patients, and their initial efficacy for many women, ERα-positive disease still accounts for more breast cancer related deaths than any other subtype. Relapse in these patients is largely due to the development of resistance to anti-estrogen therapies such as tamoxifen. While tamoxifen and its resistance mechanisms have been extensively studied from both the bench and the bedside, relatively little is known about its active metabolite endoxifen. Our group has provided evidence that endoxifen is the most potent and clinically relevant metabolite of tamoxifen, suggesting that its characterization may be crucial to understanding tamoxifen resistance.

Methods: We have developed novel endoxifen resistant MCF7 and T47D cell lines through chronic exposure to endoxifen during a period of 12-24 months. Using these models and their respective controls, we compared global gene expression profiles of endoxifen resistant cells to tamoxifen resistant cells and found marked differences between the two models. Additionally, we subjected treatment naïve cells to a genome-wide, CRISPR-mediated knockout screen to identify genes, and their associated pathways, that are likely involved in mediating endoxifen resistance.

Results: Analysis of CRISPR guide RNAs enriched or depleted in response to chronic endoxifen treatment revealed that disruption of genes regulated by dexamethasone (Dex), a potent glucocorticoid receptor (GR) agonist, enhanced cells' ability to survive and proliferate in the presence of endoxifen. These data suggest that GR activation may inhibit endoxifen resistance, and that treatment of resistant cells with Dex may restore endoxifen efficacy. Indeed, Dex treatment significantly inhibited the proliferation rates of endoxifen resistant cells by 50-60% with little to no inhibitory effects in endoxifen sensitive models. Further, Dex was shown to synergize with endoxifen in resistant cells to further suppress cell proliferation, implying that Dex treatment could be utilized as an effective therapy for endocrine resistant disease. Conditioned media harvested from cells chronically exposed to Dex also resulted in substantial inhibition of endoxifen resistant cell proliferation rates. To explore potential mechanisms of these effects, we performed RNA-seq on both treatment-naïve and endoxifen resistant cells following Dex treatment. Out of 246 genes significantly regulated by Dex in endoxifen resistant cells, we identified 61 genes that were not differentially regulated in treatment naïve cells. These genes may provide insights into the mechanisms of GR activity specific to endoxifen resistant cells.

Conclusions: To our knowledge, we have developed the first models of endoxifen resistance and have demonstrated that global transcriptomic changes that occur during this process are substantially different than those observed in tamoxifen resistant models. We have shown that activation of GR signaling elicits significant growth-inhibitory effects specifically in the setting of endoxifen resistance. These data identify the GR pathway as a potential novel therapeutic target for the treatment of endocrine resistant breast cancer.
GDC-9545: A novel ER antagonist and clinical candidate that combines desirable mechanistic and pre-clinical DMPK attributes

Ciara Metcalfe¹, Ellen Ingalla¹, Robert A Blake¹, Jae Chang¹, Anneleen Daemen¹, Tom De Bruyn¹, Jennifer M Giltnane¹, Jane Guan¹, Marc Hafner¹, Steven Hartman², Lorna Kategaya¹, Tracy Kleinheinz¹, Jun Liang¹, Vidhi Mody¹, Michelle Nannini¹, Jason Oeh¹, Savita Ubhayakar¹, Ingrid Wertz¹, Amy Young¹, Jason Zbieg¹, Wei Zhou¹, Deepak Sampath¹, Lori S Friedman¹ and Xiaojing Wang¹. ¹Genentech, South San Francisco; ²Theravance Biopharma, South San Francisco and ³Ideaya Biosciences, South San Francisco.

ER+ breast cancers depend on ER signaling throughout disease progression, including after acquired resistance to existing endocrine agents, providing a rationale for further optimization and development of ER-targeting agents. Fulvestrant is unique amongst currently approved ER ligand therapeutics due to its classification as a full ER antagonist, which is thought to be achieved through degradation of ERα protein. However, the full clinical potential of fulvestrant is believed to be limited by poor physiochemical properties and exposure limitations due to its administration by intramuscular injection.

Strategies to generate orally bioavailable molecules that retain fulvestrant's full antagonist profile but with considerably improved drug-like properties are thus being widely employed to identify next generation ER therapeutics. However, we find that therapeutic candidates that have recently emerged from prospective optimization of ER degradation, including GDC-0810 and GDC-0927, are not mechanistically equivalent. GDC-0810, GDC-0927, and fulvestrant display unique profiles in terms of ER degradation, transcriptional phenotypes and anti-proliferative potential across a panel of ER+ breast cancer cell lines. In HCI-011 (ER.WT) and HCI-013 (ER,Y537S) ER+ patient-derived breast cancer xenograft (PDX) models, GDC-0927 achieves more robust transcriptional suppression of ER than GDC-0810, and also and greater efficacy. Although displaying a more desirable mechanistic profile than GDC-0810, GDC-0927 has more rapid clearance and poor oral bioavailability, leading to a high pill burden and potential exposure limitation.

Here, we describe for the first time GDC-9545, in which the distinct liabilities of GDC-0810, GDC-0927 and fulvestrant are addressed. GDC-9545 is a non-steroidal ER ligand that is highly potent in competing with estradiol for binding and in driving an antagonist conformation within the ER ligand binding domain. Like fulvestrant, and displaying some improvements over GDC-0927, GDC-9545 consistently induces ER turnover and drives deep transcriptional suppression of ER, resulting in robust in vitro anti-proliferative activity.

GDC-9545 exhibits reduced metabolism and increased oral bioavailability relative to GDC-0927, resulting in an overall improved oral exposure in multiple species. As a result of both its mechanistic pharmacology and improved oral exposure, GDC-9545 can achieve the same degree of anti-tumor activity as GDC-0927 but at 100-fold lower doses in the HCI-013 PDX model. The in vivo efficacy of GDC-9545 in this model is greater than GDC-0810 and fulvestrant at clinically relevant exposures. The highly potent in vivo efficacy of GDC-9545 likely arises due to the particular combination of high binding potency, full suppression of ER signaling, and an improved DMPK profile when compared to GDC-0927 and fulvestrant. GDC-9545 is currently being evaluated in Phase 1 clinical trials (ClinicalTrials.gov Identifier: NCT03332797).
Timing provides context for the paradoxical effects of AMPK activation in ER+ breast cancer: Suppressing growing tumors, but promoting dormant tumor cell survival and recurrence

Todd W Miller¹, Riley A Hampsch¹, Charlotte F McCleery¹, Jason D Wells¹, Jennifer L Fields¹, Lloye M Dillon¹ and Kevin Shee¹.¹Geisel School of Medicine at Dartmouth, Lebanon, NH.

Precision oncology requires delivering the right drug to the right patient at the right time, but “time” is rarely studied preclinically before a drug enters a particular clinical setting. Despite showing efficacy against recurrent/metastatic solid tumors, drugs sometimes fail to prevent tumor recurrence when given (neo)adjuvantly. The biology and microenvironments of overt tumors likely differ substantially from dormant cancer cells. The development of preclinical models to investigate clinically dormant disease will increase understanding of residual tumor cell biology and enable the development of therapeutics for rational adjuvant trials.

Despite treatment with adjuvant anti-estrogen therapies, ~30% of patients with ER+ breast cancer (BC) experience recurrence. In contrast to other BC subtypes, ER+ relapses occur late, often appearing years to decades after initial diagnosis and treatment. This delay suggests that ER+ BC cells can undergo extended periods of clinical dormancy. We developed novel, clinically relevant xenograft models of dormancy in ER+ BC. Low systemic levels of estrogens in mice can be further suppressed by ovariectomy, mimicking the effects of aromatase inhibitor (AI)-induced estrogen deprivation (ED) therapy. In ovariectomized mice, luciferase-labeled MCF-7, HCC-1428, HCC-1500, and MDA-MB-415 cells, as well as the HCI-017 PDX model, formed palpable orthotopic tumors upon 17b-estradiol supplementation. ED induced rapid tumor regression and decreased bioluminescent signal. However, a small proportion of ER+ BC cells survived ED for >1 year in a clinically dormant, growth-suppressed state. This residual cell population stabilized after ~90 days of ED, as evidenced by stabilization of bioluminescent signal. Transcriptional and immunohistochemical analyses revealed significant upregulation of AMP-activated protein kinase (AMPK)-alpha-2 levels and activity in clinically dormant tumor cells compared to estrogen-driven or acutely ED xenografts. Dormant tumor cells were dependent upon AMPK activity for survival, as short-term pharmacologic inhibition of AMPK reduced residual bioluminescent signal.

Metformin is an AMPK-activating drug approved for the treatment of diabetes. Metformin is currently being tested as an anti-cancer agent in many clinical trials at various points in the disease progression of diverse cancer types. In our models of clinically dormant ER+ BC, AMPK activation via metformin slowed ED-induced tumor regression, promoted residual tumor cell survival, and caused earlier tumor regrowth. In vitro studies indicated that metformin promotes cell survival during ED by enhancing fatty acid β-oxidation. Conversely, metformin treatment slowed estrogen-driven tumor growth, in agreement with prior observations that metformin slows growth of various tumor subtypes. These findings suggest that AMPK activation may be efficacious against growing tumors, but deleterious when used in combination with drugs that suppress tumor growth and induce regression. More broadly, this work highlights the issue that the time in a disease course needs to be considered when testing potential anti-cancer agents such as AMPK modulators.
Genome-wide copy number analysis of cell-free DNA identified frequent chromosome 6q losses in metastatic breast cancer

Hongnan Mo¹, Xiaobing Wang¹, Ziliang Qian², Binghe Xu¹ and Fei Ma¹. ¹National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China and ²Prophet Genomics Inc, San Jose, CA.

Background:
Endocrine-resistant disease remains a leading cause of metastatic breast cancer (MBC) mortality. The molecular basis for this frustrating resistance are diverse and still largely unexplored. Next-generation sequencing analysis of cell-free DNA (cfDNA) offers minimally invasive genomic profiling of tumor alterations without tumor biopsy. Copy number alterations (CNAs) derived from cfDNA could be used to complement the genomic features in addition to actionable mutations, yet little is known regarding CNAs in endocrine-resistant MBC. We sought to analyze the utility of CNAs to monitor endocrine treatment exclusively via cfDNA and determine if CNAs is associated with progression free survival (PFS) in MBC.

Methods:
In this retrospective cohort study, we identified 61 patients with biopsy-proven MBC at a single tertiary care institution who received prior endocrine therapy in the adjuvant or metastatic setting. We performed low-pass whole-genome sequencing of cfDNA from plasma, and CNAs were analyzed by the Ultrasensitive Chromosomal Aneuploidy Detector assay. PFS was measured from the date of new treatment initiation after cfDNA collection to the date of progression or tumor-specific death. PFS analysis was performed using the Cox proportional hazard model.

Results:
The study population consisted of 61 MBC cases (40 hormone receptor-positive [HR+], 24 HER2+) with a median age of 50 years, and 28 of them had no prior MBC therapies. Median follow-up duration was 15.7 months, and median PFS was 7.5 months.

We determined tumor fraction of cfDNA for 45 out of 61 pts (73.8%). Frequent focal gains were identified, including 8p11.23 (13.1%), 8p11.21 (27.9%), 17q21.1 (36.1%), 20q13.11 (13.1%), 11q13.2-13.4 (26.2%), and 7p11.2 (3.3%), where potential oncogene FGFR1, IKBKB, ERBB2, SGK2, CCND1 and EGFR was located. Copy number estimation of HER2 from cfDNA were highly consistence with immunohistochemistry results (P<0.001) and were completely consistent with fluorescence in situ hybridization results.

Patients with high CNAs was predictive of worse PFS (median, 6.6 vs 10.6 months, hazard ratio (HR)= 2.02, 95%CI 1.01-4.04, P= 0.047) and inferior objective response of subsequent systemic treatment (33% vs 58%, P=0.030). Especially, for the HR+ patients, patients with no CAN changes experienced a better PFS (HR=3.76, 95% CI 1.39-10.2, P= 0.009). In 14 patients with primary resistance to endocrine treatment, CNAs in 6q related with ESR1 were found in 8 patients (57.1%). Meanwhile, 6 out of 14 patients with acquired resistance had CNAs in 6q (42.9%). Notably, in 40 patients with HR+ MBC, 6q loss was exclusively found in patients with endocrine-treated patients. 14 out of 28 patients with endocrine-resistance had 6q loss (50.0%), which was higher than the ones observed in HR+ MBC patients from the TCGA datasets (31%, P= 0.024).

Conclusions:
Here, we present the first large-scale CAN profile of patients with endocrine-resistant MBC to our knowledge. CNAs tracking by cfDNA is reliable and predicts worse response of the following systemic therapy. Of interest, a novel loss region, involving chromosome 6 was identified to be related with endocrine resistance, which may warrant further investigation.
The role of DAXX on enrichment of breast cancer stem cells from ER+ breast cancer

Daniel S Peiffer¹, Debra Wyatt¹, Andrei Y Zlobin¹, Ali Piracha¹, Patricia A Robinson¹, Kathy S Albain¹ and Clodia Osipo¹. 'Loyola University Chicago, Maywood, IL.

Background: Resistance to endocrine therapy (ET; tamoxifen or aromatase inhibitors) is a major cause of mortality for women with estrogen receptor-positive (ER+) breast cancer (BrC). One mechanism of ET-resistance is due to heterogeneity of breast tumors, comprised of differentiated cells plus undifferentiated breast cancer stem cells (BCSCs). Survival of BCSCs requires Notch signaling and thus determining how it is activated in response to ET may elucidate a new target of therapeutic significance. We found that expression of the transcriptional repressor, DAXX, was inversely correlated with Notch inhibition in a human pre-surgical biomarker trial of ER+ BrC patients (ClinTrials.gov NCT00756717). Further, it has been demonstrated that expression of a sumoylation enzyme, UBC9, is dependent on ERα activation, and that it sumoylates DAXX. We hypothesized that targeting ERα by ET depletes UBC9 causing destabilization of the DAXX protein, resulting in Notch activation and enrichment of BCSCs.

Methods: A panel of ER+ BrC cells were grown in conditions of 5nM estradiol (E2) or ET conditions of E2 deprivation. Expression levels of NOTCH4, other BCSC-associated genes, UBC9 and DAXX were quantified by real-time PCR (RTPCR). BCSC survival was assessed by the mammosphere forming assay. To test if ET increases BCSC by destabilizing DAXX, DAXX was depleted or overexpressed by cell transfection. To assess the role of DAXX in tumor initiating potential, an extreme limiting dilution assay (ELDA) was conducted by injection of normal or DAXX-depleted cells into the mammary fat pads of female mice. Nuclear levels of DAXX protein were quantified by cell fractionation and enrichment of DAXX at the promoter regions of BCSC-associated genes was assessed by chromatin immunoprecipitation (ChIP). Protein levels of DAXX following UBC9 depletion were determined by cell fractionation.

Results: ET or siRNA depletion of DAXX increased survival of BCSCs, and expression of BCSC-associated genes, including NOTCH4. Conversely, DAXX overexpression under ET-conditions inhibited BCSC-associated gene expression and survival. ELDA demonstrated that cells depleted of DAXX had a higher estimated stem cell frequency compared to DAXX-expressing cells. Cell fractionation indicated that DAXX protein was concentrated in the nucleus, and these levels were decreased by ET treatment. ChIP studies revealed an enrichment of DAXX binding at the promoter regions of BCSC-associated genes (NOTCH4, SOX2, OCT4, NANOG), which was lost following ET. UBC9, but not DAXX mRNA levels, are dependent on activation of ERα, and depletion of UBC9 resulted in a decrease in DAXX levels.

Conclusions: These results suggest that E2 activation of ERα increases UBC9 levels, allowing for stabilization of nuclear DAXX in ER+ BrC cells, where it represses expression of BCSC-associated genes. Conversely, ET depletes UBC9, destabilizing DAXX, ultimately relieving repression of BCSC-associated genes and promoting increased BCSC survival. This would potentially result in resistance to ET. Thus, new strategies to stabilize DAXX protein during ET may prevent induction of BCSC gene expression and enrichment of BCSCs, improving therapeutic outcomes in ER+ BrC.

Non-canonical, clinical ESR1 mutations promote resistance to antiestrogen therapies

Weiyi Toy, Kathryn E Carlson, Teresa A Martin, Pedram Razavi, Michael Berger, Jose Baselga, Geoffrey Greene, John Katzenellenbogen and Sarat Chandarlapaty. 1Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center (MSKCC), New York, NY; 2University of Illinois at Urbana-Champaign, Chicago, IL; 3Breast Medicine Service, MSKCC, New York, NY; 4Weill Cornell Medical College, New York, NY and 5University of Chicago, Chicago, IL.

ESR1 hotspot mutations have been identified in 30-40% of patients with ER+ MBC and promote resistance to aromatase inhibitors (AIs). Identification of these mutations has been aided by the use of plasma DNA for their detection, however many such tests only survey for hotspot mutations. In this study, we examined the prevalence, biologic and clinical significance of mutations in ESR1 that lie outside previously described hotspots (E380Q, Y537, D538G). Using next generation sequencing of tumor DNA from over 4000 patients with breast cancer, we have identified numerous somatic alterations in ESR1. Among the somatic alterations were mutations detected in the transcription activation function-1 (AF-1), DNA binding domain, dimerization interface and C-terminus of ER.

We characterized the functional significance of these non-canonical mutations alongside hotspot mutations, starting with assays of ER driven transcription and deduced several classes of mutations: (1) mutations that weakly promote ligand-independent activity, (2) mutations that led to ligand-independent activity comparable to estradiol stimulation, and (3) mutations that resulted in impaired transcriptional activity. Class 2 mutations remain localized at amino acids 536-538, while the class 1 mutations are observed in various domains of ESR1, including the DNA binding domain and dimerization interface. Several Class 3 mutations were found in proximal to Helix 12, highlighting the critical role of this region.

Clinically, non-canonical mutations were not exclusively observed among patients treated with AI, as there were several mutations from SERM/SERD treated patients. We thus examined the effects of different mutants on their sensitivity to ER antagonists, such as fulvestrant or tamoxifen. The data revealed key differences between the different classes of mutants; with majority of the class 2 mutants exhibiting reduced sensitivity to the antagonists compared to wild type. This also correlated with the relative binding affinities (RBA) of the mutants to fulvestrant and 4-hydroxytamoxifen, in which the RBA of class 2 mutants (Y537S and D538G) were significantly lower than wild type, perhaps accounting for their reduced sensitivities. Nevertheless, it appeared that all mutants could be effectively inhibited either by higher concentrations or more potent ER antagonists, implying a continued ability to distort ER into the antagonist conformation. Interestingly, several Class 1 mutants showed weak agonism in response to specific antagonists raising the possibility of their role in SERM/SERD resistance. Taken together, the data demonstrated that not all ESR1 mutations affect receptor function or respond to antiestrogen therapies similarly. These data also imply the importance of more broad sequencing coverage of ESR1 in the clinic to effectively capture the spectrum of biologically relevant alleles.
Splicing factor ESRP1 controls ER-positive breast cancer progression by altering metabolic pathway genes

Yesim Gokmen-Polar', Yuan Gu', Xiaoping Gu' and Sunil S Badve'. 'Indiana University, Indianapolis, IN.

Background Epithelial Splicing Regulatory Protein (ESRP1) is a key splicing factor that regulates Epithelial-to-Mesenchymal Transition (EMT) splicing program. Our previous study demonstrated that high levels of ESRP1 are associated with poor prognosis in human ER-positive (ER+) breast tumors in an independent manner of EMT process. We next explored the potential mechanisms that contribute to the role ESRP1 in endocrine therapy-resistant breast cancer.

Methods Probe based-Human Transcriptome Array 2.0 (HTA; Applied Biosystems/Thermo Fisher) was performed using RNAs from control and ESRP1 knockdown cells (LCC2 versus 2C3 ESRP1 and LCC9 versus 9C2 ESRP1) of endocrine resistant breast cancer. Functional enrichment analyses were performed using the DAVID functional annotation tool (http://david.abcc.ncifcrf.gov/). To confirm the functional importance of ESRP1 on regulation of cellular metabolism, we have performed experiments that analyze the metabolic substrate flux in response to ESRP1 knockdown in resistant cells (The Seahorse XFp Cell Energy Phenotype Assay). Differentially expressed genes were validated using Western blotting assay.

Results Transcriptome profiling of ESRP1 in 2C3 and 9C2 knockdown models revealed differentially expressed genes using HTA 2.0 platform. In LCC2 versus 2C3 ESRP1 knockdown, expression of 1186 genes (1263 transcripts) have been altered significantly, while 413 genes (432 transcripts) have been significantly regulated in LCC9 versus 9C2 ESRP1 knockdown with FDR<0.1. Of these significant genes, 34 downregulated and 68 upregulated (102 genes total) were shared by both 2C3 and 9C2 ESRP1 knockdowns. Using the DAVID Functional Annotation Clustering Tool, we identified the biological processes altered significantly in response to ESRP1 knockdown. The most significant annotation clusters downregulated in ESRP1 knockdown consists of fatty acid metabolism/lipid metabolism (SCD, ACACA, FASN, ACAT2, PLCH1, and HPGD), and oxireductase processes (SCD, PHGDH, FASN, DHTKD1 and HPGD). We confirmed the altered metabolic function using the Seahorse analyzer. These analyses confirmed that ESRP1 knockdown altered the glycolysis rate (extracellular acidification rate; ECAR) in both tamoxifen-resistant and fulvestrant-resistant models. In addition, ESRP1 knockdown decreased the mitochondrial respiration in tamoxifen-resistant cells, but not fulvestrant resistant cells. Using Western blotting, we validated the altered levels of fatty acid synthase (FASN) and Stearoyl-CoA desaturase 1 (SCD1), key enzymes in fatty acid metabolism. Phosphoglycerate Dehydrogenase (PHGDH), a poor prognosis marker in cancers including breast cancer, was also downregulated in response to ESRP1 knockdown. Taken together, we have demonstrated a novel functional impact of ESRP1 on the regulation of tumor growth at the functional and molecular level independent of EMT.

Conclusions For the first time, we show the role of ESRP1 in altering the cellular metabolism thereby contributing to tumor growth. The study provides a molecular evidence for the role of altered metabolism in determining adverse prognosis of ER+ breast cancer via the control of ESRP1, a splicing factor. Further studies to determine the therapeutic value are underway.
Tracking ESR1 mutation clonal evolution in breast cancer using in situ mutation detection

Carlos Martinez-Pérez¹, Arran K Turnbull¹, Maki Tanioka², Anu Fernando¹, Lorna Renshaw³, Jane Keys³, Amy Wheless², Amy Garrett², Joel Parker², Xiaping He², Andrew H Sims¹, Lisa A Carey², Charles M Perou² and J Michael Dixon³. ¹Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom; ²Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill and ³Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom.

Background: Approximately 70% of breast cancers (BCs) are estrogen receptor positive (ER+). Not all ER+ cancers respond to endocrine therapy (ET) and many eventually develop acquired resistance. Next-generation sequencing (NGS) has shown ESR1 mutations (ESRMs) are present in 10-50% of recurrent/metastatic cancers treated with aromatase inhibitors (AIs). Many of these mutations are located in the ligand-binding domain of ER, so they can lead to constitutive activation. This suggests ESRMs are a major mechanism of acquired resistance to endocrine therapy (ET) and numerous studies have shown a link between ESRMs and reduced sensitivity to 2nd line ET. The aim of this project was to investigate the incidence and clonal evolution of common ESRMs in BCs resistant to multiple sequential ETs using NGS, as well as novel PCR and in situ mutation detection methods.

Methods: We have optimised an allele-specific real-time PCR (rtPCR) assay and an in situ mutation detection method (ER-ISMD) for the assessment of ESRMs. Both have been designed to identify a missense gain-of-function D538G mutation with a single nucleotide-resolution in formalin-fixed paraffin-embedded (FFPE) BC tissues.

Two unique cohorts have been studied:
(A) 20 post-menopausal women (PMW) with ER+ BC who acquired resistance to letrozole and were treated with up to 4 subsequent lines of ET. Serial RNA and DNA from 3-5 cancer samples per patient (58 samples from 20 patients) were analysed by Ribo0-RNAseq, DNA exome sequencing, rtPCR and ER-ISMD.
(B) 150 PMW with ER+ BC who developed local (n=79), lymph node (n=59) or distant (n=12) recurrences on 1st line adjuvant letrozole, anastrozole or tamoxifen. Of these, 48 patients developed subsequent recurrences on 2nd line ET. Tissue samples from each recurrence and matched primary BC were collected.

Results: In cohort A, 5/20 patients (20%) had expansion of a D538G ESR1 mutation clone at time of resistance 1st line ET (3:letrozole, 1:anastrozole, 1:tamoxifen). The mutant allele frequency (MAF) increased further in the 4 BCs treated with 2nd line ET (2:tamoxifen, 2:exemestane) and further still in the 1 BC who received 3rd line exemestane. 0/6 patients with ESRM responded to subsequent ET. Allele-specific rtPCR and ER-ISMD have been used to validate these findings and also identified low frequency ESRM clones in the sequential samples prior to the development of clinical resistance, that were not reported by NGS. Both methods have also been applied to screen tissues from patients in cohort B, where ESRMs have also been identified in recurrent samples. Complete analysis is currently ongoing.

Conclusions:
· ESRMs develop and expand in some BCs as a mechanism for acquired resistance to ET and are associated with a lack of response to subsequent standard ETs.
· Allele-specific rtPCR can detect ESRMs and is more cost-effective and easier to use than NGS for ER mutation analysis.
· Some ESRMs predate clinical resistance.
· ER-ISMD is a novel approach that allows for identification and visualisation of the distribution of mutant clones in morphologically intact FFPE tissue.
· ER-ISMD has the potential to become a clinically useful tool to help direct the use of 2nd line ET in routine care.
Enhancing response to estrogen therapy in ER+ breast cancer with novel scheduling and dosing regimens

Nicole A Traphagen¹, Sarah R Hosford¹ and Todd W Miller¹,². ¹Dartmouth College, Hanover, NH and ²Norris Cotton Cancer Center, Lebanon, NH.

Estrogen therapy was historically used as a standard breast cancer treatment from the 1940s until the introduction of tamoxifen in the 1970s. Although a clinical trial directly comparing the synthetic estrogen diethylstilbestrol and tamoxifen in post-menopausal patients demonstrated no significant difference in progression-free survival between the two, tamoxifen showed a more favorable toxicity profile and estrogens fell out of favor. However, 1 in 3 patients eventually recur and develop advanced disease that is resistant to all available anti-estrogens. Estrogen therapy is being resurrected in clinical trials for advanced, heavily pre-treated ER+ breast cancer. These studies demonstrate that ~30% of patients respond to treatment with estrogens. However, little pharmacologic work has been done to optimize the schedule and method of hormone delivery.

Estrogen therapies such as 17b-estradiol (E2) and ethinylestradiol are typically administered orally several times daily. Toxicities have been observed with such regimens, and there is no evidence that the maximally efficacious doses or schedules are being used clinically. We used two in vivo tumor models to preclinically define the optimal dosing schedule and method of E2 delivery that maximizes response. WHIM16 patient-derived ER+ breast cancer xenografts (PDX) and C7-2-HI ER+ murine mammary adenocarcinoma allografts both grow in ovariectomized (“estrogen-deprived”) mice, and regress in response to E2 treatment.

We tested an array of E2 doses and delivery methods [e.g., oral gavage, subcutaneous (s.c.) injection, s.c. pellet, and s.c. osmotic pump] in mice bearing C7-2-HI and WHIM16 tumors to determine optimal methods for inducing maximal and sustained tumor regression. We found that oral dosing is less effective at inducing tumor regression than other methods. However, intermittent high-dose estrogen given as 1 mg of E2 orally every 14 days both prevented tumor growth and did not result in toxicity, suggesting that intermittent dosing should be further examined as a means to increase therapeutic index.

Although estrogen therapy induces clinical response in a subset of patients with ER+ disease, nearly all patients eventually experience disease progression and develop resistance to the therapeutic effects of estrogen. Clinical observations suggest that some cancers that progressed on estrogen therapy are re-sensitized to anti-estrogen treatment. We therefore examined whether resistance to estrogen therapy could be prevented by preemptively cycling estrogen therapy with estrogen deprivation in mice. Discontinuous scheduling of E2 and estrogen deprivation was tested with either 1 or 4 weeks on E2 treatment, followed by estrogen deprivation until tumors re-grew to baseline volume, then E2 treatment was repeated. In the WHIM16 tumor model, the 4-week E2 treatment cycle nearly doubled time to recurrence compared to mice treated continuously with E2. Surprisingly, there was no difference in time to recurrence between groups treated with the 1-week cycle vs. continuous E2. However, tumors that re-grew on continuous E2 were sensitized to estrogen deprivation. These collective findings warrant clinical testing of schedules of alternating estrogen and anti-estrogen therapies.
Total estrogenic activity during neoadjuvant therapy with letrozole and exemestane – An intra-patient cross-over comparison using the AroER tri-screen

Nazli Bahrami¹, Gregory Chang², Noriko Kanaya², Torill Sauer¹,³, Berit Gravdehaug¹, Shiuan Chen² and Jürgen Geisler¹,³.
¹Akershus University Hospital, Lørenskog, Norway; ²Beckman Research Institute of the City of Hope, Duarte, CA and ³Institute of Clinical Medicine, University of Oslo, Campus AHUS, Lørenskog, Norway.

Background. Aromatase inhibitors (AIs), letrozole (Femar®/Femara®) and exemestane (Aromasin®), are widely used anti-hormonal drugs for breast cancer. Both compounds strongly reduce circulating estradiol levels in postmenopausal women. In the setting of metastatic breast cancer, these drugs may be used after another, causing new responses in selected patients by switching to the alternative drug after progressing on the first choice. This well-known "lack of cross resistance" has been recognized for some time and is documented by several clinical trials. However, the precise explanation for this clinical observation is still unknown. The availability of mechanistic information may lead to an improved strategy against hormone-sensitive breast cancer.

Patients and methods. NEO-LET-EXE was a neoadjuvant, randomized, open-label, intra-patient cross-over trial. Postmenopausal patients with estrogen receptor (ER) positive (>50%), HER-2 negative, locally advanced breast cancer were enrolled. Sequential blood samples (obtained at baseline, after 2 months and 4 months of treatment) were available from 29 patients. All patients were randomized to sequential treatment starting with either letrozole (2.5 mg o.d.) or exemestane (25 mg o.d) for 2 months followed by another 2 months on the alternative compound. The total estrogenic activities in the collected blood samples were determined using AroER tri-screen assay developed by the Chen laboratory. The assay utilizes MCF-7aro ERE cells which contain both aromatase and ER. The samples were assayed in the presence as well as the absence of letrozole, to estimate relative contributions of estrogen and estrogen+androgen to the activities, respectively.

Results. Using the highly sensitive AroER tri-screen assay, estrogenic activity were detected at three time points in all blood samples. Importantly, a significantly higher total estrogenic activity was found during therapy with exemestane compared to letrozole in 23 out of 26 patients. Only in three patients, the activity was higher during therapy with letrozole compared to exemestane. When letrozole was included in the assay, the estrogenic activities in most samples collected during exemestane treatment were further reduced, suggesting that low levels of androgen were present in samples from exemestane treatment. Four samples collected after exemestane treatment and three after letrozole treatment had higher activities than baseline samples when assay was carried out with letrozole.

Discussion. Our results suggest the AroER tri-screen to be a very sensitive method to estimate the overall estrogen-mediated activity in human samples. Significant higher levels of estrogenic activity in human serum were observed during exemestane than those during letrozole treatment. Our observations, that additional letrozole could reduce further the estrogen activity in the exemestane-treated samples, demonstrate probably residual aromatase activity during therapy with exemestane alone. In addition to distinguish the effects of exemestane and letrozole, our results also demonstrate that the assay can also potentially detect the effects of estrogenic mimics.
Local network topology differences between early and late recurrence in ER+ breast cancers

Robert Clarke¹, Mike Dixon²,³, Lu Jin¹, Dominic Pearce⁴, Arran Turnbull²,³, Cigdem Selli²,³, Rong Hu¹, Alan Zwart¹, Yue Wang⁴, Jason Xuan⁴, Surojeet Sengupta¹, Andy Sims² and Minetta C Liu⁵.
¹Georgetown University, Washington, DC; ²University of Edinburgh, Edinburgh, Scotland, United Kingdom; ³Breast Cancer Now Research Labs, Edinburgh, Scotland, United Kingdom; ⁴Virginia Tech Research Center, Arlington, VA and ⁵Mayo Clinic, Rochester, MN.

Background: Late recurrence is characteristic of ER+ breast cancers. Despite an apparently effective adjuvant endocrine therapy, many breast cancers recur years after their initial endocrine treatment. Why some tumors recur early (<3 years) and some recur later (>5 years) is poorly understood. If systemic endocrine therapies killed all cells, recurrence would reflect only the appearance of new disease. Thus, we hypothesized that cells that survive and lie dormant may be driven, in part, by altered wiring of their cell death signaling. We, therefore, studied how cell death signaling is differentially wired in primary tumors that will recur early versus those that will recur later.

Method: Genes involved in apoptosis, autophagy, ferroptosis, necrosis, and pyroptosis were identified from KEGG to initiate network feature analysis of gene expression data from public and our first in-house gene expression dataset. Data were collected from ER+ breast cancer pre-endocrine treatment samples with up to 20 years follow-up. Publicly available datasets used were GSE6532, GSE2034, GSE7390, GSE17705, GSE12093, and TCGA. We applied our Knowledge-fused Differential Dependency Network (KDDN) analysis tool to the public datasets; KDDN has provided powerful new insights into signaling in breast and other cancers. Common gene-gene interactions (edges) predicted in at least two different datasets were extracted from all KDDN analyses results. To strengthen the relevance of these features, predicted network edges that represent known protein-protein interactions (PPI) were identified from the STRING database, and these edges were noted in the signaling graphs. Final network graphs were constructed using the common edges from all overlaid networks. We conducted IPA analysis on all nodes in the final network and selected those incorporating network hubs. We took a similar approach to our second in-house dataset, which we used for independent testing. Here, patients were included if their tumor exhibited an initial reduction in volume of at least 40% by four months in response to neo-adjuvant Letrozole. Patients were then classified into two groups during follow-up of up to 3.7 years: i) initial tumor size reduction followed by continued response (expected to recur late); ii) initial reduction followed by tumor regrowth (expected to recur early). KDDN analysis was performed on pretreatment samples from these two groups and a network created annotated with PPI information.

Results: MAPK8 and CYCS (Molecular Mechanisms of Cancer, p=1.58E-52), TNFRSF1A Neuroinflammation Signaling Pathway, p=1.26E-54), RELA, and NFKB1 (Colorectal Cancer Metastasis Signaling, p=7.94E-35), were identified as hubs. Hubs may be critical signaling components driving the differences between tumors that will become dormant and recur late. Connections between SLC25A6 and SQSTM1 (p = 0.008), BIRC2 and GABARAP (p = 0.021) in the early group, and AKT3 and IRS2 (p = 0.014) in the late group, were shared between the two final networks. With longer follow-up time on the second in-house dataset, we will better define the two groups and identify additional common phenotype specific gene-gene interactions.
ARV-471, an oral estrogen receptor PROTAC degrader for breast cancer

John J Flanagan¹, Yimin Qian¹, Sheryl M Gough¹, Monica Andreoli¹, Mark Bookbinder¹, Gregory Cadelina¹, John Bradley¹, Emma Rousseau¹, Ryan Willard¹, Jennifer Pizzano¹, Craig M Crews², Andrew P Crew¹, Ian Taylor¹ and John Houston¹. ¹Arvinas LLC, New Haven, CT and ²Yale University, New Haven, CT.

ARV-471, an estrogen receptor (ER) alpha PROTAC, is a hetero-bifunctional molecule that facilitates the interactions between estrogen receptor alpha and an intracellular E3 ligase complex, leading to the ubiquitylation and subsequent degradation of estrogen receptors via the proteasome. ARV-471 robustly degrades ER in ER-positive breast cancer cell lines with a half-maximal degradation concentration (DC₅₀) of ~ 2 nM. PROTAC-mediated ER degradation decreases the expression of classically-regulated ER-target genes (PR, GREB1, TFF) and inhibits cell proliferation of ER-dependent cell lines (MCF7, T47D). Additionally, ARV-471 degrades clinically-relevant ESR1 variants (Y537S and D538G) and inhibits growth of cell lines expressing those variants. In an immature rat uterotrophic model, ARV-471 degrades rat uterine ER and demonstrates no agonist activity. Daily, oral-administration of single agent ARV-471 (3, 10, and 30 mpk) leads to significant tumor volume regressions of estradiol-dependent MCF7 xenografts and concomitant tumor ER protein reductions of >90% at study termination. Moreover, when a CDK4/6 inhibitor is combined with ARV-471 in the MCF7 model, even more pronounced tumor growth inhibition is observed (~130% TGI), accompanied by significant reductions in ER protein levels. In an ESR1 Y537S, hormone-independent patient-derived xenograft model, ARV-471 at 10 mpk completely inhibited growth and also reduced mutant ER protein levels. Taken together, the preclinical data of ARV-471 supports its continued development as a best-in-class oral ER PROTAC-degrader.
Preclinical in vitro and in vivo evaluation of seribantumab, a human epidermal growth factor receptor-3 antibody, combined with standard therapies in hormone receptor-positive and human epidermal growth factor receptor-2-negative breast cancer models

Sara Ghassemifar¹, Greg Finn¹, Hong Zhang¹, Jennifer Richardson¹, Geoffrey Kuesters¹, Sergio Santillana¹ and Marc Pipas¹.
¹Merrimack Pharmaceuticals, Inc., Cambridge, MA.

**Background:** Heregulin (HRG)-induced human epidermal growth factor receptor-3 (HER3) signaling is associated with a poor response to standard-of-care across multiple cancers. Seribantumab is a human monoclonal antibody that targets and downregulates HER3 and blocks HRG from binding to HER3. In a randomized Phase 2 trial in hormone-positive (HR+) and human epidermal growth factor receptor-2-negative (HER2–) metastatic breast cancer (mBC), HRG+ patients appeared to have shortened progression free survival when receiving exemestane monotherapy and benefited from addition of seribantumab to this regimen. Activation of the HRG-HER3 axis has been implicated in mediating resistance to fulvestrant in HR+ HER2– breast cancer cellular models. We investigated the role of HRG-HER3 in mediating resistance to CDK4/6 inhibitors (i.e., palbociclib) alone or in combination with fulvestrant. Additionally, we evaluated in vitro and in vivo anti-tumor activity of seribantumab with these therapies and elucidated potential mechanisms of action (MoA).

**Methods:** In vitro growth inhibition and MoA were investigated primarily in a HR+ HER2– MCF7 cell line by CellTiter-Glo viability assay and cell cycle profiling. In vivo anti-tumor activity of seribantumab plus fulvestrant and/or palbociclib was assessed in the orthotopic MCF7 mouse model.

**Results:** HRG desensitized MCF7 cells to in vitro anti-tumor effects of fulvestrant and CDK4/6 inhibitors, whereas HRG-HER3 inhibition by seribantumab restored this sensitivity through the inhibition of HRG-mediated retinoblastoma (RB) protein phosphorylation and G1-S progression. CDK4/6 inhibitor treatment resulted in increased HRG mRNA expression suggesting that HRG-HER3 might serve as an escape route from CDK4/6 inhibition. In the in vivo MCF7 mouse model, seribantumab potentiated the anti-tumor activity of fulvestrant and CDK4/6 inhibitor, consistent with in vitro findings.

**Conclusion:** HRG-HER3 signaling impairs the activity of CDK4/6 inhibitors alone or in combination with fulvestrant in preclinical HR+ HER2– breast cancer models. HER3 blockade by seribantumab restores the drug sensitivity. This study provides rationale for the ongoing SHERBOC study (NCT03241810) testing seribantumab in combination with fulvestrant in postmenopausal women with HRG+ HR+ HER2– mBC who have received prior CDK4/6 inhibitor.
Targeting CDK4/6 and IGF1R or insulin receptor synergistically inhibits growth of endocrine sensitive and endocrine resistant breast cancers

Katelyn Hoff1 and Deepali Sachdev1. 1Masonic Cancer Center, University of Minnesota, Minneapolis, MN.

Estrogen receptor positive (ER+) breast cancers are treated with hormonal therapies such as tamoxifen or aromatase inhibitors. More than 30% of patients with early-stage ER+ breast cancer treated with endocrine therapy will relapse and all patients with metastatic breast cancer expressing ER eventually acquire resistance to hormonal therapy. Endocrine therapy resistant patients therefore require novel therapeutic options. Insulin-like growth factors (IGFs) and insulin signaling via the type I IGF receptor (IGF1R) and insulin receptor (IR) respectively regulate breast cancer biology. Unfortunately, IGF1R targeted therapies failed to show a benefit in prolonging either disease-free or overall survival in clinical trials. In pre-clinical models acquired resistance to tamoxifen results in loss of IGF1R and enhanced sensitivity to IR signaling. Inhibition of mTOR alone relieves the negative feedback loop regulating levels of the adaptor protein IRS-1, which mediates proliferative effects of IGFs and insulin and enhanced phosphorylation of Akt. The ribosomal protein S6 kinase (S6K) phosphorylates IRS-1 on serine residues targeting it for proteasomal degradation, and this negative feedback regulation is important in attenuating IGF and insulin signaling. Cyclin dependent kinases (CDKs) 4 and 6 are required for cell cycle progression. CDK4/6 inhibitors have recently been approved for treatment of ER+, Her2- advanced breast cancers and these such as palbociclib and abemaciclib block phosphorylation of retinoblastoma. IGFs and insulin stimulate cell cycle progression and increase cyclin D1 levels in breast cancers. Therefore, we hypothesized that CDK4/6 inhibition combined with IGF1R or IR targeting, to block mitogenic functions of IGF or insulin signaling, could be a viable therapeutic option in endocrine sensitive and endocrine resistant breast cancer, respectively. Parental MCF-7 and T47D were more sensitive to palbociclib compared to matched cells with acquired resistance to tamoxifen, MCF-7/TamR and T47D/TamR. Palbociclib also blocked IGF-I and insulin stimulated entry into cell cycle leading to G0/G1 arrest in ER+ breast cancer cells. Unlike mTOR inhibitors that upregulated IRS-1 levels leading to increased phosphorylation of Akt through IGF1R/IR, palbociclib did not affect IRS-1 levels and did not enhance phosphorylation of Akt in ER+ breast cancer cells. Combination of palbociclib with an IGF1R inhibitory antibody (huEM164), but not IR antibody (83-7), was better at inhibiting growth of endocrine sensitive MCF-7 and T-47D cells than either drug alone. Further, in a formal synergy study using the method of Chou-Talalay, the combination index of palbociclib and the IGF1R antibody was <1 for MCF-7 parent cells, indicating the two drugs synergistically inhibit growth. Combination of palbociclib with an IR antibody synergistically inhibited the growth of endocrine resistant MCF-7/TamR cells. Our data show that cotargeting CDK4/6 and IGF1R is more effective in endocrine sensitive but cotargeting CDK4/6 and IR is more effective in tamoxifen resistant breast cancer cells. These data indicate that targeting CDK4/6 and IR could be a therapeutic option for patients with endocrine resistant disease.
FGFR4 is a novel druggable target for recurrent ER-positive breast cancers

Kevin M Levine¹, Kai Ding¹, Nolan Priedigkeit¹, Matthew J Sikora², Nilgun Tasdemir¹, Li Zhu¹, George C Tseng¹, Rachel C Jankowitz¹, David J Dabbs¹, Priscilla F McAuliffe¹, Adrian V Lee¹ and Steffi Oesterreich¹. ¹University of Pittsburgh, Pittsburgh, PA and ²University of Colorado Denver, Denver, Aurora, CO.

Background
Breast cancer recurrence is a major clinical problem for estrogen receptor positive (ER+) disease, even decades after initial surgery. These long-term recurrences are a challenge for invasive ductal carcinoma (IDC), and are particularly frequent for the histological subtype of invasive lobular carcinoma (ILC). To study the long-term endocrine resistance seen in ILC patients, our lab recently generated six long-term estrogen deprivation (LTED) models of ILC cells and performed RNA-Sequencing to identify differentially expressed genes that ostensibly allow these cells to grow in the absence of estrogen. We overlapped these results with a previously published microarray dataset of tamoxifen-resistant cells, and found that FGFR4 is the most consistently overexpressed gene in the setting of acquired resistance to endocrine therapy in ILC cells. From a recent publication of RNA-Seq from other LTED models, FGFR4 RNA overexpression is also seen in all five IDC cell lines.

Hypothesis
FGFR4 is an important mediator of acquired endocrine resistance in breast cancer.

Methods
To study the role of FGFR4 in vitro, we used multiple shRNAs and specific small molecule inhibition for growth assays. To study the role of FGFR4 in de novo resistance to endocrine therapy, we collected 129 well curated ER+ ILC tumor specimens and performed gene expression analysis on the pre-treatment samples using a custom NanoString panel. To study the role of FGFR4 in acquired resistance, we collected over 50 pairs of primary-metastatic ER+ tumors and performed exon capture based RNA-Sequencing.

Results
FGFR4 inhibition decreases parental and LTED cell growth in classic 2D conditions and in colony formation assays. The LTED cells, with higher FGFR4 expression, are more sensitive to its inhibition. For the parental cells, combination FGFR4 and ER-targeting drugs results in synergistic decreases in growth. In our database of primary ILC clinical samples, increased expression of FGFR4 is predictive of shorter time to distant recurrence. Among primary-recurrent tumor pairs, FGFR4 is an outlier expression gain in 20/50 (40%), spanning all recurrence sites studied (i.e. local recurrences, and metastases to the brain, bone, ovaries, and GI tract). Finally, in analyzing large cohorts of metastatic tumors, there is a significant enrichment of hotspot FGFR4 mutations in tumors originating in the breast, with >2% of metastatic ILC tumors containing such a mutation.

Conclusion/Future studies
FGFR4 may play an important role in de novo resistance to endocrine therapy in ILC and acquired resistance in both ILC and IDC. Ongoing studies include overexpression of wild-type and FGFR4 hotspot mutations in ILC and IDC cell lines to determine growth and metastatic phenotypes.
Enhancing the activity of a novel estrogen receptor coregulator binding modulator (ERX-11) against ER-positive therapy resistant breast cancer

Suryavathi Viswanadhapalli\(^1\), Shihong Ma\(^3\), Tae-Kyung Lee\(^2\), Gangadhara R Sareddy\(^1\), Xihui Liu\(^3\), Dede Ekoue\(^3\), Aparna Alluri\(^3\), Yiliao Luo\(^1\), Kara Kassee\(^2\), Carlos Arteaga\(^3\), Prasanna Alluri\(^3\), Susan E Weintraub\(^1\), Rajeshwar Rao Tekmal\(^1\), Jung-Mo Ahn\(^2\), Ganesh V Raj\(^3\) and Ratna K Vadlamudi\(^1\). \(^1\)UT Health and Mays Cancer Center, San Antonio, TX; \(^2\)UT Dallas, Dallas, TX and \(^3\)UT Southwestern, Dallas.

**Background:** We had previously reported a novel small molecule, ERX-11, that directly interacts with ER and blocks the interaction between a subset of coregulators with both native and mutant forms of ER. ERX-11 effectively blocks ER oncogenic signaling and has potent anti-proliferative activity against therapy-sensitive and therapy-resistant human breast cancer cells. To enhance the clinical translation of ERX-11, we sought to pursue both lead optimization and evaluate combinations of ERX-11 with other approved agents in breast cancer.

**Methods:** We designed, synthesized and tested 500 derivatives of ERX-11 in multiple models of ER+ breast cancer. We also tested combinations of ERX-11 with multiple agents, including other ER targeting agents, chemotherapies and CDK4/6 inhibitors. We tested the effect of combination therapy using breast cancer cells with acquired resistance (Tamoxifen, Letrozole, Ribociclib resistant) and engineered models that express ER mutations. *In vitro* activity was tested using Cell titer glo, MTT, and apoptosis assays. Mechanistic studies were conducted using Western blot, reporter gene assays and RNA-seq analysis. Xenograft, patient derived xenograft (PDX), patient derived explant (PDE) and xenograft derived explant (XDE) models were used for preclinical evaluation and toxicity.

**Result:** Evaluation of 500 analogs of ERX-11 identified a number of leads with differential activity against ER+ and ER- breast cancer cells, identified several analogs including ERX-144, 208, 296, 315 with nanomolar potency against ER+ and therapy-resistant ER+ breast cancers. Validation of the mechanism of action of these analogs is ongoing. The combination of ERX-11 and palbociclib significantly blocked ER-mediated and ER-coregulators mediated oncogenic signaling and showed potent anti-proliferative activity against both endocrine therapy-sensitive and resistant breast cancer cells. In addition, ERX-11 inhibited ribociclib-resistant ER+ cell proliferation in a dose dependent manner. Mechanistic studies using IP-Mass spectrometry demonstrated that ERX-11 and palbociclib blocks the interaction between larger subset of coregulators with ER in therapy resistant breast cancer models. ERX-11 and palbociclib both exhibited potent anti-proliferative activity against therapy-sensitive and therapy-resistant ER+ve breast cancer cells, in xenograft models and in PDEs. Importantly, combination therapy of ERX-11 and palbociclib synergistically reduced the growth of tamoxifen and letrozole resistant xenograft tumors compared to either drug alone. Mass spec based DIA analyses and RNA-seq studies revealed that combinational treatment uniquely activated p53, unfolded response mediated apoptotic pathways, altered DNA damage response and suppressed E2F and Myc target genes. Biochemical studies confirmed combination therapy significantly altered E2F1, ER and DNA damage response pathways.

**Conclusion:** We have successfully pursued two avenues to improving ERX-11 for clinical translation. We have developed ERX-11 analogs with higher potency against ER+ breast cancer. We have shown that combinational treatment with ERX-11 and palbociclib may overcome endocrine therapy resistance and CDK4/6 inhibitor (ribociclib) resistance.
Molecular stratification of ER+/HER2- breast cancer cell lines to predict sensitivity to targeted agents

Lauren Bathurst, Linda Liao, Cheryl Crozier, Nicola Lyttle, Richard Marcellus, Jane Bayani, Rima Al-awar, John Bartlett and Melanie Spears. 1University of Toronto, Toronto, ON, Canada and 2Ontario Institute for Cancer Research, Toronto, ON, Canada.

Background: Approximately 70% of all breast cancers are estrogen receptor positive (ER+) at diagnosis and are dependent on estrogen signaling for tumour growth and proliferation. Some ER+ breast cancers can be effectively treated with adjuvant endocrine therapies including tamoxifen, but despite favorable improvements in overall survival, resistance to endocrine therapy is common and has been associated with dysregulation of several signaling pathways. These pathways can be targeted with specific inhibitors, many of which are currently under clinical investigation. However currently there is a lack of predictive biomarkers to identify which patients should receive treatment with targeted therapy. The goal of this study was to determine whether alterations in specific signaling pathways can be identified and used to stratify breast cancer cell lines to the most effective experimental treatments.

Methods/Results: Fifteen ER+/HER2- cell lines were characterized using a NanoString PAM50-like assay as well as next generation sequencing and were then stratified according to alterations in three key signaling pathways: CCND/CDK, PI3K/AKT/mTOR and FGFR. High-throughput small-molecule screenings were performed to identify the IC50 values of 24 inhibitors across the strata. Variation in inhibitor sensitivity was observed between cell lines based on molecular alterations. Cell lines with a PIK3CA mutation in combination with a CDK-pathway alteration were more sensitive to CDK inhibitors (50 to 120nM) than cell lines with alterations in the CDK-pathway alone or PIK3CA mutations alone (170nM to >5000nM). In addition, cell lines with the dual alterations demonstrated stronger synergy between CDK and PI3K-pathway inhibitors compared to either alteration alone.

Conclusions: The results suggest that stratification according to molecular alterations in specific signaling pathways may predict sensitivity to targeted inhibitors in a panel of ER+/HER2- luminal breast cancer cell lines. Work is ongoing to identify the optimal synergistic inhibitor combinations for each strata. The ultimate goal is to translate this work into a novel personalized medicine approach, using molecular stratification based on a combination of molecular events in a functional pathway as opposed to single genes.
Characterization of FGFR1/2 genetic alterations reveals novel fusions of FGFR1 in Chinese breast cancer

Yulei Wang, Liping Guo, Li Cao, Minghan Jia, Lingzhu Wen, Chongyang Ren, Guochun Zhang and Ning Liao. Cancer Center Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China.

Background: Deregulation of fibroblast growth factor receptor 1 (FGFR1) signalling has been extensively studied in various tumor types, and has been implicated in driving endocrine resistance in breast cancer. Genetic alterations of FGFR1, especially FGFR1 amplification, is one of particularly important mechanisms leading to enhanced FGFR signaling in breast cancer. However, the prevalence of FGFR1/2 genetic variations in Chinese breast cancer patients has not been well explored.

Methods: To investigate the characteristics of FGFR1 and FGFR2 genetic variations in Chinese breast cancer, we employed customized next-generation sequencing panel to screen the somatic mutation or copy number variations of FGFR1/2 in primary breast cancer tissues by using two ongoing breast cancer Cohorts, in which we have recruited 289 of early breast cancer patients (EBC Cohort) and 74 of advanced breast cancer patients (ABC Cohort).

Results: In EBC Cohort, we found FGFR1 amplification in 9.0% (26/289) patients and FGFR2 amplification in 2.1% (6/289) patients, and also found 3 of somatic FGFR1 mutations (FGFR1 p.W4C; p.E334K; p.V396I) and 2 of FGFR2 mutations (FGFR2 p.S702L; p.Y779*). Unlike the comparable prevalence of FGFR2 genetic variations in 2.8% (8/289) of EBC Cohort and 2.7% (2/74; one amplification event and one FGFR2 p.E499D mutation) of ABC Cohort, there were more FGFR1 genetic alterations in ABC Cohort (27%; 20/74 patients; p<0.001), including 19 events of FGFR1 amplification and 1 of FGFR1 c.2186+20G>A intron mutation. More importantly, we identified 5 novel FGFR1 fusion genes in our cohorts, including TACC1-FGFR1, FGFR1-KCNU1, FGFR1-MIR1268A, FGFR1-LZTS1-AS1 and FGFR1-RNF5P1. Although FGFR1-TACC1 fusion gene has been previously reported in breast cancer and TACC1 is fused to the C-terminal of FGFR1 protein leading to aberrant activation of FGFR1, we found TACC1 was fused to the N-terminal of FGFR1 at exon 6 of FGFR1 in our study. In addition, we identified and verified FGFR1-MIR1268A fusion gene at mRNA level using RNA-seq analysis, and further found this fusion gene might result in the truncation of FGFR1.

Conclusions: Collectively, we characterized the prevalence of FGFR1/2 genetic alterations in Chinese breast cancer, and identified 5 of novel FGFR1 fusion genes. The potential roles for novel FGFR1 fusion genes in regulating breast cancer cellular biology and in affecting the efficacy of endocrine therapy have been under the investigation in our laboratory, and the result from which will help us better elucidate the molecular mechanism of FGFR1 in driving the resistance of endocrine therapy. This study was supported by funding from National Natural Science Foundation of China (Grant No. 81602645), Guangdong Provincial Natural Science Foundation (Grant No. 2016A030313768) and Research Funds from Guangzhou Science and Technology Bureau (Grant No. 201707010418 and 201804010430).
Identification of preclinical mechanisms driving acquired resistance to endocrine therapy in estrogen-receptor positive (ER+) breast cancer cells

Christy Ong\textsuperscript{1}, Anneleen Daemen\textsuperscript{1}, Karl Merrick\textsuperscript{1}, Tom O’Brien\textsuperscript{1}, Lori Friedman\textsuperscript{1} and Georgia Hatzivassiliou\textsuperscript{1}. \textsuperscript{1}Genentech, Inc, South San Francisco, CA.

Estrogen Receptor positive (ER+) breast cancer accounts for the majority of breast cancer cases and standard of care for these tumors is treatment with endocrine therapy, including the blockade of estrogen production (i.e. aromatase inhibitors; AIs) as well as the use of antagonists of ER function, i.e. selective estrogen receptor modulators (SERMs, i.e. tamoxifen) and selective estrogen receptor degraders (SERDs, i.e. fulvestrant). Despite the initial dependency of ER+ breast tumors on estrogen and ER for their survival and proliferation, treatment in the metastatic setting invariably leads to therapeutic resistance. While mechanisms of resistance to AIs include mutations in the estrogen receptor gene ESR1, less is known about mechanisms of resistance to SERMs and SERDs, thus it is essential to further investigate the latter, in order to successfully treat relapsed patients. To pre-clinically model cell-autonomous acquired resistance to these agents, we used T47D, an ER+ and p53- estrogen-responsive cell line treated with increasing concentrations of the SERM/SERD hybrid (SSH) ER-targeting agent GDC-0810 over the period of several months during which individual clones with acquired resistance to GDC-0810 were selected. GDC-0810-resistant clones were cross-resistant to other endocrine agents, including SERMs (tamoxifen) and SERDs (fulvestrant), consistent with general loss of dependency on ER. Surprisingly, the cells also lost sensitivity to palbociclib, the latter likely linked to their loss of one copy of the retinoblastoma (Rb) tumor suppressor gene. Comprehensive genetic and phenotypic characterization of the resistant clones relative to the parental cells revealed multiple mutations and deletions in DNA repair and cell cycle genes, and associated defects in DNA repair and cell cycle checkpoints. Cell cycle, proteomic, and mRNA expression analysis of parental versus resistant clones at baseline and upon DNA damage, identified a distinct cell cycle profile in the GDC-0810-resistant clones, characterized by accumulation of cells in the mitotic phase. A broad chemical screen identified pharmacologic inhibitors of cell cycle regulators and chemotherapeutic drug classes that preferentially target the ER-independent, GDC-0810 resistant clones compared to the parental cells. Our work provides novel insights into mechanisms and biomarkers of acquired resistant to estrogen therapies in ER+ breast cancer and reveals the acquisition of actionable dependencies that may potentially be exploited in resistant tumors. Furthermore, our studies provide rationale for testing specific chemotherapy regimens upon endocrine resistance accompanied by cell cycle and DNA repair checkpoint dysfunction in ER+ breast cancer.
Investigating the incidence of ESR1 gene amplification in breast cancers resistant to multiple endocrine agents

Arran K Turnbull¹, Carlos Martinez-Perez¹, Sarah Mok¹, Maki Tanioka², Anu Fernando¹, Lorna Renshaw³, Jane Keys³, Amy Wheless², Amy Garrett², Joel Parker², Xiaping He², Andrew H Sims¹, Lisa A Carey², Charles M Perou² and J Michael Dixon³.

¹Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Arab Emirates; ²Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill and ³Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom.

Background: Around 70% of all breast cancers (BCs) are estrogen receptor positive (ER+), but some do not respond to endocrine therapy (ET) and many eventually develop resistance. ESR amplification (ESRA) linked to an increase in ESR1 gene expression is known to occur in some cancers that are endocrine resistant. However, the incidence of ESRA has been the object of debate and its clinical significance remains unclear. This study aimed to investigate the incidence of ESRA in BCs resistant to multiple sequential ETs and optimise a fluorescence in-situ hybridisation (FISH) methodology to robustly detect ESRA.

Methods: Two unique cohorts have been studied:
(A) 20 post-menopausal women with ER+ BC with acquired resistance to letrozole, subsequently treated with up to 4 different lines of ET. Serial RNA and DNA from 3-5 cancer samples per patient (58 samples from 20 patients) were analysed by Ribo0-RNAseq and DNA exome sequencing;
(B) 18 post-menopausal women who developed ER+ BC recurrences on 1st line adjuvant letrozole, then on 2nd line tamoxifen and subsequently on 3rd line exemestane. Tissues were collected at the time of each surgery.

We have optimised a FISH method to assess ESRA in these tissues.

Results: In cohort A, 6/20 patients developed ESR1 gene amplification (ESRA) at some point during treatment. In 5 of these cases, ESRA was only found while on 2nd or 3rd line exemestane but was not present on acquired resistance to previous letrozole or tamoxifen. 1 patient had ESRA at the time of first recurrence on letrozole. The FISH method showed concordance with the genomic analysis. This suggests that ESRA may be associated with BCs that are treated with and then become resistant to exemestane.

ESRA is also evident in samples from Cohort B, which includes 18 exemestane resistant cases. The complete analysis is ongoing.

Conclusions:
· ESRA can be seen in ER+ recurrent BCs.
· ESRA may be associated with BCs treated with 2nd or 3rd line exemestane.
· The frequency of ESRA in endocrine and exemestane resistance can now be ascertained using an optimised FISH-based method, which is more cost-effective than alternative genomic and biochemical methods.
A potential role for IL6ST mediating endocrine resistance in breast cancer via interaction with the ER signaling pathway

Duniya H Mosly¹, Arran K Turnbull¹, Simon P Langdon¹ and Andrew H Sims¹. ¹University of Edinburgh, Edinburgh, United Kingdom.

Background
Interest in the ubiquitously expressed transmembrane receptor IL6ST (gp130) has developed as it has been identified as a predictive biomarker of endocrine treatment response in breast cancer patients and is included in the 'Endopredict' test. At least seven cytokines (IL-6, OSM, LIF, IL-11, CNTF, IL-27, CT-1) signal via IL6ST. Interleukin-6 (IL-6) can mediate effects via two signaling pathways; classic signaling (through the membrane-bound IL-6 receptor, IL-6R) and trans-signaling (via non-signaling membrane-bound soluble IL-6R, sIL-6R). Both pathways may occur in parallel and activate cells. Crosstalk between the ER signaling pathway and IL6ST through STAT3 has been identified and implicated in the conversion from ER responsiveness to non-responsiveness.

Method
A panel of 3 ERa+ luminal breast cancer cell lines (MCF-7, T47D, ZR-75-1) were chosen to examine IL6ST expression by western blot, gel electrophoresis and qRT-PCR. Proliferation assays (SRB) were carried out to investigate the effects of seven cytokines (IL-6, OSM, LIF, IL-11, CNTF, IL-27, CT-1) on cell growth. The action of both IL-6 and Oncostatin M (OSM) on cell migration and downstream signaling pathways (pSTAT3 and pERK1/2) was studied. The extent of trans-signaling occurrence and interaction between cytokines and estrogen was investigated using proliferation assays.

Results
Three cell lines (MCF-7, T47D, ZR-75-1) were shown to express varying levels of full-length IL6ST, with MCF-7 having the least expression. Gel electrophoresis and qRT-PCR confirmed the presence of all previously described IL6ST soluble forms in the three cell lines. Surprisingly, the growth response to the cytokines was variable across the cell lines. IL6 caused a modest increase in growth in MCF-7 but produced inhibition in ZR-75-1. OSM and LIF stimulated growth in MCF-7, whereas OSM inhibited ZR-75-1 and LIF had no effect. Interestingly, no significant effect on growth was seen in T47D with any of the cytokines except IL-11 which generated a significant growth effect on T47D cells. Both STAT3 and MAPK/ERK pathways were activated to different extents in the three cell lines as a result of OSM and IL-6 activation, whereas cells migration was only stimulated in ZR-75-1. The trans-signaling pathway significantly enhanced the growth inhibition in ZR-75-1. Estrogen eliminated the effect of both IL-6 and OSM on MCF-7 growth, while both cytokines decreased estrogen-induced cell proliferation in ZR-75-1. There was no effect in T47D.

Conclusion
These results indicate:
• The presence of both classic and trans-signaling occurrence in breast cancer cell lines.
• Differential patterns of pSTAT3 and pERK1/2 signaling which could help explain the variation in responses to the cytokines.
• IL6ST full-length form is the most abundant form in all three cell lines under basal conditions.
• The levels and roles of the different IL6ST soluble forms will be further studied after estrogen stimulation.
• The effect of IL6ST silencing in the presence of estrogen and tamoxifen on cell growth and the gene expression currently being examined.
Efficacy and safety of low-dose everolimus in Chinese HR-positive, HER2-negative metastatic breast cancer patients

Xiying Shao¹, Xiaojia Wang¹, Zhanhong Chen¹ and Yabing Zheng¹. 'Zhejiang Cancer Hospital, Hangzhou, China.

**Background:** Everolimus has been testified to be effective among postmenopausal women with hormone receptor-positive human epidermal growth factor receptor-2 negative (HR+/HER2-) metastatic breast cancer (MBC). However, everolimus at dose of 10mg was accompanied by a higher incidence of mTOR-inhibitor class-effect adverse events (AEs) which usually leading to dose reduction or interruption. Additionally, some studies suggested that there was no correlation between dose intensity (5 vs. 10 mg labeled dose) and efficacy. Consequently, we conducted the present study aiming to explore the efficacy and safety of everolimus at dose of 5 mg plus endocrine therapy in Chinese population.

**Methods:** 68 HR+/HER2- MBC patients were included in this exploratory study who received everolimus at the dose of 5mg in Zhejiang Cancer Hospital between September 2014 and September 2017. Progression free survival(PFS) and overall survival(OS) were estimated by the Kaplan-Meier method, and the hazard ratios(HRs) and corresponding 95% confidence intervals(CIs) were estimated using the Cox proportional hazard model. Besides, objective response rate(ORR), clinical benefitrate(CBR) and safety profile were also evaluated.

**Results:** After a median follow up of 14 months, PFS was 5.3 months (95%CI 4.2-6.4), and OS was immature. 16(23.5%) were at the first or second-line, 52(76.5%) were at third-line or later. PFS for the first and second-line is significantly longer than that for the third-line or later (12.9 months vs. 4.6 months, \( P=0.009, \) HR=0.395, 95% CI=0.192-0.811). 11(16.2%) achieved partial response (PR), 42(61.7%) had stable disease (SD), and 15(22.1%) reported progressive disease (PD). The ORR and CBR were 16.2%, 35.2%, respectively. Most common all grade adverse events were stomatitis(26.5%), fatigue(10.0%), infection(11.8%), thrombocytopenia(5.9%), anemia(4.4%), hyperglycemia(4.4%). The most common ≥3 grade adverse events were stomatitis(4.4 %), infection(2.2%) and thrombocytopenia(1.1%).

**Conclusions:** The combination of low-dose everolimus and endocrine therapy was highly effective especially at the earlier line in Chinese population. And the safety profiles were similar to previous studies but the incidences were greatly lower. The combination of low-dose everolimus and endocrine therapy may become a proper option for HR+/HER2- MBC.
Developing an immunohistochemistry protocol to detect neurofibromin as an effective, simple, and rapid method to identify NF1-negative breast cancer patients

Jianheng Peng, Ze-yi Zheng, Burcu Cakar, Jing Li, Purba Singh, Adam T Szafrain, Fabio Stossi, Julien Dubrulle, Michael A Mancini, Rena Mao, George Miles, Matthew J Ellis, and Eric C Chang. 1Baylor College of Medicine, Houston, TX.

**Background:** Neurofibromin is a key tumor suppressor, well-known as a GTPase-Activating-Protein (GAP) to attenuate Ras signaling. It is encoded by the *NF1* gene, so named because its inactivation was first discovered to cause Neurofibromatosis type 1, an autosomal dominant genetic disorder. We have recently reported that nonsense (NS) and frameshift (FS) mutations, but not missense mutations, in *NF1* are associated with a markedly higher risk of relapse and death in early stage ER+ breast cancer after adjuvant tamoxifen monotherapy (Griffith et al. *in press*). Surprisingly, despite being best known as a GAP, no missense mutations inactivating NF1’s GAP activity were found in our cohort. We have evidence that these *NF1* NS/FS mutations cause the resulting mRNAs to be degraded, leading to depletion of the entire NF1 protein. In a separate study that was presented here last year, we showed that NF1 is also an ER co-repressor, which partially explains why the loss of the single tumor suppressor NF1 is so detrimental — because this turns on two potent oncogenic pathways. Thus far there is no effective means to assess loss of NF1 protein in cancer. The objective of this project is to identify these aggressive NF1-negative breast cancers by establishing an immunohistochemistry (IHC) protocol with a valid NF1 antibody in order to properly find and treat them in the future.

**Methods:** A monoclonal antibody was raised against the C-terminus of NF1. Immunostaining as well as IHC was performed using a set of breast cancer cell lines with varying degrees of NF1 protein levels, including several NF1 null-like cell lines as negative controls. To assess whether the IHC protocol can be used on patients, NF1+ and NF1−PDXs as well as patient biopsies were examined.

**Results:** We have purified a monoclonal antibody against NF1 (m376). By immunostaining, a strong NF1 signal can be seen in T47D cells, which have four copies of the *NF1* gene. In contrast, there was barely any signal in MDA-MB-175VII cells, which lack detectable NF1 due to *NF1*FS mutations. While NF1 appears mostly cytoplasmic, 10-15% can be seen in the nucleus. Nuclear NF1 levels can be further increased by the nuclear export blocker leptomycin-B, suggesting that NF1 is shuttled in and out of the nucleus. IHC staining confirmed these features of NF1. In addition, a weak nuclear signal can be seen in cancer cells carrying *NF1*FS mutations. Experiments are on-going to assess how to analyze tumor samples for NF1 loss and whether *NF1*FS mutations cause expression of truncated proteins that are nuclear.

**Conclusion:** Our results suggest that the m376 antibody has the potential to be used for IHC, provided that samples known to be NF1+ or NF1− are included as controls. The success of this project will have particular clinical impact in telling us who should not be treated by tamoxifen. Furthermore, we have an approved clinical trial protocol to assess the concept that these NF1-patients should instead be treated by combining a Ras pathway inhibitor and a SERD.
Metabolic enzyme PFKFB4 activates transcriptional coactivator SRC-3 to drive aggressive metastatic breast cancer

Subhamoy Dasgupta¹, Vivek Anand¹, Hasper John¹, Abhisha Sawant Dessai¹, Eriko Katsuta¹, Kazuaki Takabe¹ and Bert O’Malley². ¹Roswell Park Comprehensive Cancer Center, Buffalo, NY and ²Baylor College of Medicine, Houston, TX.

Background: Metabolic rewiring is one of the central hallmarks of cancer progression and survival to support anabolic and energetic demands. Tumor cells constantly alter their metabolic state in response to oncogenic stimuli, nutrient availability, and interaction with immune cells however the precise regulation that precedes the metabolic alteration is poorly understood. Here we report a direct interaction of glycolytic enzyme PFKFB4 with transcriptional coregulator SRC-3. PFKFB4 functions as a critical regulator of Warburg effect and our study reveals that upon glucose stimulation PFKFB4 activates SRC-3 driving an invasive-metastatic breast cancer.

Methods: Molecular experiments were performed to understand the transcriptional activation of SRC-3 by PFKFB4 enzyme. Chromatin immunoprecipitation and gene expression studies were performed to investigate the functions of PFKFB4/SRC-3 crosstalk on transcriptional regulation. Metabolomics and isotope tracing studies were performed to identify the metabolic adaptations regulated by PFKFB4/SRC-3 in breast tumors. PFKFB4-knockout was established using CRISPR-Cas9 system and functional studies were carried out to define its role in tumor cell proliferation, invasion-migration, and breast to lung metastasis. Human breast tumor samples were evaluated to identify the clinical importance of PFKFB4/SRC-3 crosstalk in patients.

Results: Molecular studies revealed that PFKFB4 enzyme phosphorylates SRC-3 at serine 857 (S857) enhancing its transcriptional activity, whereas either suppression of PFKFB4 or ectopic expression of a phosphorylation-deficient SRC-3 mutant S857A (SRC-3S857A) significantly abolished SRC-3-mediated transcriptional output (p<0.000001). Functionally, PFKFB4-driven SRC-3 activation drives glucose flux towards the pentose phosphate pathway enabling purine synthesis by transcriptionally upregulating the expression of enzyme transketolase (TKT). Deletion of PFKFB4 by CRISPR-Cas9 system resulted in significantly reduced proliferation (p<0.05) and migration-invasion (p<0.001) compared to wildtype breast tumor cells. Ablation of SRC-3 or PFKFB4 suppressed in vivo breast tumor growth and prevents metastasis to the lung from an orthotopic setting (p<0.0001). PFKFB4 and phosphorylated SRC-3 levels are significantly increased in breast tumors (p=0.02), whereas, in patients with the basal subtype, PFKFB4 and SRC-3 drive a common protein signature that correlates with the poor survival of TNBC patients (p=0.03).

Conclusion: Our data suggest that the Warburg pathway enzyme PFKFB4 acts as a molecular fulcrum that couples sugar metabolism to transcriptional activation by stimulating SRC-3 to promote aggressive metastatic tumors. It also provides first evidence how Warburg pathway drives aggressive breast tumorigenesis by directly activating powerful oncogene SRC-3. Our work suggests that targeting the PFKFB4–SRC-3 axis may be therapeutically valuable in breast tumors that are notably dependent on glucose metabolism.

Thyroid hormone replacement therapy shortens survival in hormone receptor positive early stage breast cancers

Reema S Wahdan-Alaswad¹, Susan M Edgerton¹, Hiba S Salem¹, Bolin Liu¹ and Ann D Thor¹. ¹University of Colorado Anschutz Medical Campus, Aurora, CO.

Purpose
A majority of breast cancer (BC) patients have clinical or subclinical thyroid disease as compared to a minority of unaffected women. This comorbidity has been recognized for over a century. We hypothesized that thyroid hormone (TH) promotes breast carcinogenesis and growth, and may reduce survival for patients on long term TH replacement therapy (THRT). We sought to validate these findings in a study of BC patients and investigate mechanisms of hormonal interaction using model systems.

Methods
Over 800 consecutively diagnosed lymph node (LN) negative, mostly chemo-naïve invasive BC patients from 1976 to 1993 were evaluated. Clinical and outcomes data were derived from medical records (10.2 year median follow up). Primary tumors from surgery (typically mastectomy with node dissection) were analyzed for receptors and biomarkers. Univariate and multivariate statistical methods were used. In vivo and in vitro studies were performed using immortalized human BC cell lines and patient derived xenograft(PDX) models.

Results
LN- THRT vs. non-THRT BC patients showed no significant differences in clinical, histologic or prognostic data. THRT was significantly associated with a higher relative risk (RR) of recurrence 2.376 fold (p<0.0001) and disease specific survival (DSS), 2.02 fold (p=0.0183). Subset analyses showed only steroid receptor (SR) positive patients had a deleterious interaction with THRT (mean RFS 68mo., RR 3.431, p<0.0001), mean disease specific survival (DSS) 81mo., RR 3.960, p=0.0001) as compared to non-THRT patients (mean RFS 206mo., mean DSS 223mo.). Tamoxifen (Tam) treated patients on THRT had an especially poor outcome, DFS p=0.0004. Using in vitro methods we showed potent induction of cell proliferation by estrogen (E2) and/or thyroid hormone (TH) across a wider range of concentrations in SR+, but not SR- BC (P<0.0001). Fulvestrant (ICI) significantly inhibited these interactions, whereas Tam failed to provide an equivalent antagonistic effect. In some SR+ cells, Tam further increased cell proliferation. In vivo studies showed co-localization of ER and THα were upregulated by co-administration of E2 + TH. Tam further induced co-localization, whereas ICI lowered receptor expression and co-localization. ER+ PDX tumors in mice with continuous E2 showed enhanced tumorigenesis with TH (tumor growth (p<0.0001), tumor weight (mg) (p=0.0052) and Ki67 labeling (p=0.001)). Mice on E2 + TH with PDX tumors treated with Tam showed enhanced tumor growth and proliferation (p<0.0001), whereas ICI inhibited and in some cases eliminated tumors. RNA-seq data performed on our ER+ PDX tumors treated with hormone combinations +/- Tam show that E2 + TH potently upregulates numerous cell cycle and hormone regulated genes.

Conclusion
We show statistically significant interactions between THRT at the time of BC diagnosis, early relapse and shortened survival in SR+ (but not SR-) Stage I BC patients. In vitro and in vivo BC models confirm these deleterious interactions. Mechanistically we observe co-localization of the cognate receptors and activation of ER, with downstream upregulation of cell cycle and hormone regulated genes. These interactions are blocked by ICI, whereas Tam fails to block and may in fact enhance tumorigenesis.
Estrogen receptor beta elicits anti-cancer effects in triple negative breast cancer through suppression of NFκB signaling

Kisrten Aspros1, Adam Nelson2, Zhenqing Ye1, Zhifu Sun1, Igor Chernukhin2, Jason Carroll2, James Ingle1, Matthew Goetz1 and John Hawse1. 1Mayo Clinic, Rochester, MN and 2Cambridge Research Institute, Cambridge, United Kingdom.

**Background:** Triple Negative Breast Cancer (TNBC) affects approximately 15-20% of BC patients, yet accounts for a disproportionately higher rate of BC morbidity and mortality, in part due to lack of targeted therapies. Using well-validated antibodies, Estrogen Receptor Beta (ERβ) protein has been shown to be expressed in approximately 25% of TNBCs and is associated with improved patient outcomes. Using multiple ERβ +/- TNBC cell lines and PDX models, we have demonstrated that ligand-mediated activation of ERβ by estradiol (E2) decreases cell proliferation, invasion, and migration in vitro, as well as primary tumor growth and metastatic spread in vivo.

**Methods:** To determine the mechanisms by which ERβ elicits these anti-cancer effects, we elucidated the ERβ transcriptome and cistrome via Microarray and ChIPseq, respectively, in TNBC cells stably expressing ERβ in a doxycycline-inducible manner. We also performed gene expression and luciferase assays to assess the impact of ERβ on NFκB signaling, followed by ChIP-PCR and ChIPseq to assess how ERβ modifies chromatin architecture near NFκB target genes.

**Results:** Pathway analysis of ERβ-regulated genes identified NFκB signaling as one of the most suppressed pathways in response to E2 treatment. Indeed, numerous NFκB target genes were among the most down-regulated genes following E2 treatment but only in the presence of ERβ expression. Chromatin Immunoprecipitation followed by sequencing (ChIPseq) revealed that ERβ primarily associated with estrogen response elements (EREs), but was also enriched around NFκB binding sites following E2 treatment. In fact, 12% of all ERβ binding sites were enriched for NFκB response elements and ERβ was shown to physically associate with NFκB protein. Using an NFκB reporter construct and qPCR, ERβ was shown to block TNFα-mediated induction of NFκB signaling and NFκB target gene expression. Globally, RNAseq identified 200 genes to be significantly regulated by TNFα in TNBC cells, of which 81 were significantly altered in the presence of E2+TNFα. ChIPseq demonstrated that ligand-mediated activation of ERβ significantly diminished an activating histone mark (H3K27Ac) at many of these NFκB target genes while enhancing a repressive mark (H3K27Me3). These modifications are also associated with recruitment of the histone methyltransferase, EZH2, to enhancer elements of these NFκB target genes. Drug-mediated blockade of HDAC and EZH2 activity reversed suppression of NFκB target gene expression by ERβ.

**Conclusions:** Our data suggest that ERβ may elicit its anti-cancer effects in part via formation of a novel co-repressor complex consisting of ERβ, NFκB, and EZH2. These data are in keeping with prior observations of the importance of NFκB signaling as it relates to TNBC cell proliferation and invasion, and that decreased expression of NFκB target genes is associated with improved outcomes in TNBC patients. Currently, a Mayo Breast SPORE prospective study is underway to investigate the role of estradiol in ERβ expressing TNBC and to further evaluate the cross-talk between ERβ and NFκB signaling in TNBC.
Myc as a poor prognostic marker for ER+ inflammatory breast cancer (IBC): Quantitative estrogen receptor (ER) expression analysis and gene expression analysis in ER+ IBC vs non-IBC

Toshiaki Iwase\textsuperscript{1,2}, Kenichi Harano\textsuperscript{3}, Hiroko Masuda\textsuperscript{4}, Kumiko Kida\textsuperscript{1,2}, Jose Rodrigo Espinosa Fernandez\textsuperscript{1,2}, Kenneth R Hess\textsuperscript{5}, Ying Wang\textsuperscript{5}, Wendy A Woodward\textsuperscript{1,5}, Rachel M Layman\textsuperscript{1,5}, Luc Dirix\textsuperscript{8}, Steven J Van Laere\textsuperscript{6}, François Bertucci\textsuperscript{7} and Naoto T Ueno\textsuperscript{1,2}.

\textsuperscript{1}Morgan Welch Inflammatory Breast Cancer Research Program and Clinic, The University of Texas MD Anderson Cancer Center, Houston; \textsuperscript{2}Section of Translational Breast Cancer Research, The University of Texas, Houston, TX; \textsuperscript{3}Section of Translational Breast Cancer Research, The University of Texas MD Anderson Cancer Center, Houston, TX; \textsuperscript{4}National Cancer Center Hospital East, Kashiwa, Chiba, Japan; \textsuperscript{5}Showa University Hospital, Shinagawa, Tokyo, Japan; \textsuperscript{6}The University of Texas MD Anderson Cancer Center, Houston, TX; \textsuperscript{7}Institut Paoli-Calmettes, Marseille, France and \textsuperscript{8}Oncology Center, Sint-Augustinus Hospital, Antwerp, Belgium.

**Background**
Estrogen receptor-positive (ER+) primary inflammatory breast cancer (IBC) has a poorer prognosis than ER+ primary non-IBC. Our objective was to determine the association between ER positivity and survival outcome in order to elucidate the biological reason that ER+ IBC is more aggressive than non-IBC.

**Methods**
We retrospectively determined the relationship between ER expression by immunohistochemistry staining and neoadjuvant chemotherapy response as well as survival outcome for 189 patients with ER+ and HER2-negative (HER2-) IBC and 896 case-matched patients with stage III non-IBC seen at MD Anderson Cancer Center between January 1989 and April 2015. We performed gene expression (GE) analysis for 39 patients with ER+/HER2- IBC and 40 patients with non-IBC to detect genes that are specifically overexpressed in IBC. Logistic regression and Cox proportional hazards model were used to determine the predictive and prognostic value of percentages of cells positive for ER and progesterone receptor (PR) among the patients with ER+/HER2- IBC and non-IBC. Recursive partitioning analysis (RPA) was used to determine the optimal cutoff points for ER% and progesterone receptor (PR) % that maximized differences in survival. The identified cutoff points were tested in an external cohort of 192 ER+/HER2- IBC patients from Institut Paoli-Calmettes in France.

**Results**
The median values for ER% for IBC and non-IBC were 85 (range, 1-100) and 90 (range, 1-100), respectively. The logistic regression model demonstrated a lack of a relationship of ER% with pathological complete response rate to neoadjuvant chemotherapy both in IBC (P=0.29) and non-IBC (P=0.14). Expression of ER was significantly associated with distant disease-free survival (DDFS); hazard ratio (HR), 0.56 [95% CI, 0.37-0.83] per 50% increase in ER%; (P<0.05). Also, ER% was significantly associated with overall survival (OS); HR, 0.40 [95% CI, 0.25-0.63] per 50% increase in ER%; (P<0.05). RPA showed that 91.5% and 9.0% were the optimal cutoff points for ER% and PR%, respectively, for DDFS and overall survival in IBC patients. However, the cutoff points could not be validated in the French external cohort. In the GE study, 84 genes were detected as significantly distinguishing ER+ IBC from non-IBC. Among the top 15 canonical pathways shown by IPA, the ERK/MAPK signaling pathway, PDGF pathway, insulin receptor signaling pathway, and IL-7 signaling pathway were associated with the ER signaling pathway. MYC upregulation was observed in all of these four pathways. Indeed, ER+/HER- IBC had significantly higher MYC amplification compared to those with non-IBC (P<0.05) and higher MYC level was associated with poor relapse free survival for IBC (HR, 1.85 [95% CI, 1.05-2.70], P<0.05).

**Conclusions**
Increased ER positivity was significantly associated with improved survival in ER+/HER- IBC patients. ER+/HER- IBC had several activated pathways with MYC upregulation compared to non-IBC. MYC upregulation was associated with a poor survival outcome for ER+/HER- IBC. The results indicate that MYC is a key gene for understanding the aggressive biological behavior of ER+/HER- IBC.
Targeting the androgen receptor with seviteronel, a CYP17 lyase and AR inhibitor, in triple negative breast cancer

Jordan M Reese¹, Beatrice L Babbs¹, Jessica L Christenson¹, Nicole S Spoelstra¹, Anthony Elias², Joel R Eisner³, Edwina S Baskin-Bey³, Jay Gertz⁴ and Jennifer K Richer¹.¹University of Colorado Anschutz Medical Campus, Aurora, CO;²University of Colorado, Aurora, CO;³Innocrin Pharmaceuticals, Inc., Durham, NC and ⁴University of Utah, Salt Lake City, UT.

Background: Androgen receptor (AR) protein is expressed across breast cancer (BC) subtypes, including up to 50% of triple negative breast cancers (TNBC) and it is often maintained in metastases. Our research demonstrated that TNBC cell lines rely on increased AR for anchorage independent survival, mammosphere formation, tumor initiation, and other stem-cell like properties. Further, AR mRNA levels increased in circulating tumor cells in the blood as compared to levels in the primary tumors of mice harboring human patient derived xenografts (PDX). Seviteronel (SEVI), a CYP17 lyase and AR inhibitor that blocks androgen and estrogen biosynthesis and AR activation, is in phase 2 clinical development for men and women with AR+ solid tumors, including advanced BC and has clinical activity in both basal and LAR subtypes (Innocrin data on file).

Hypothesis: We hypothesized that targeting both androgen biosynthesis and AR activation with an agent such as SEVI would decrease tumor growth in preclinical models of AR+ TNBC.

Methods: Genes regulated by AR under anchorage independent conditions with and without 10 nM dihydrotestosterone (DHT) were identified by AR chromatin immunoprecipitation (ChIP)-seq, RNA-seq, and Ingenuity Pathway Analysis. In vitro activity of SEVI was assayed in AR+ TNBC cell lines (MDA-MB-453 and SUM159). The IC₅₀ of SEVI was determined via crystal violet. Soft agar colony formation assays and growth on poly-HEMA coated plates measured anchorage independent growth. In vivo, an AR+ TNBC patient derived xenograft (HCI-009, generated by Dr. Alana Welm) was grown in NSG mice given either DHT vs. vehicle control or, in a separate experiment, SEVI (150 mg/kg/day PO) vs. vehicle control.

Results: ChIP-seq and RNA-seq in MDA-MB-453 demonstrated that AR chromatin binding and gene regulation increased under anchorage independent conditions in a ligand dependent manner and showed an increase in mTOR signaling, aryl hydrocarbon receptor signaling and metabolism. SEVI inhibited proliferation of AR+ TNBC in a dose-dependent manner and growth on soft agar. In vivo, the AR+ TNBC HCI-009 PDX exhibited a significant increase in tumor volume with DHT indicating AR dependence. SEVI treatment also decreased HCI-009 tumor volume (p=0.0054) and rate of growth (p=0.0146). Nuclear AR protein and classical AR-regulated genes such as KLK3 and FKBP5 were increased with DHT in the HCI-009 xenograft tumors and decreased in mice treated with SEVI and were confirmed at the protein level.

Conclusion: These results further demonstrate the activity of SEVI, a CYP17 lyase and AR inhibitor, in preclinical models of AR+ TNBC. Use of AR targeting agents may be a rational treatment approach for a subset of patients with AR+ TNBC since such tumors may respond less well to chemotherapy than other TNBC molecular subtypes. We continue to identify markers of AR dependence/responsiveness to AR-targeted therapy.
Progesterone receptor (PR) isoform-specific expansion of breast cancer stem-like cells occurs through a phospho-PR/FOXO1 driven signaling axis

Thu H Truong¹, Amy R Dwyer¹, Caroline H Diep¹ and Carol A Lange¹. ¹University of Minnesota, Masonic Cancer Center, Minneapolis, MN.

Luminal breast cancers account for ~75% of cases and are positive for progesterone receptor (PR) and estrogen receptor (ER) expression. PR is a classical ER-target gene and is used as a biomarker of ER activity; however, a growing body of evidence supports the role of PR as an important modifier of ER actions and a key driver of luminal breast cancer progression.

Progesterone signaling is mediated by two PR isoforms: full-length PR-B and truncated PR-A, which lacks the N-terminal 164 amino acids. Little is known about PR isoform-specific actions in PR-expressing breast tumors, given that total PR expression is measured clinically. Herein, we sought to identify phenotypic differences in luminal breast cancer cells (T47D) overexpressing PR-A (T47D-YA) or PR-B (T47D-YB). We demonstrate that PR-B expression is required for anchorage-independent colony formation, while PR-A expressing cells fail to proliferate in soft agar. PR-B driven proliferation has been mapped to PR phosphorylation events, which include MAPK or CDK consensus sites such as Ser294. We demonstrate that in contrast to previous reports, PR-A is well phosphorylated at Ser294 in response to progestins (e.g. R5020) using our custom phospho-PR (Ser294) polyclonal antibody. Interestingly, Ser294 phosphorylation of PR-A occurs more rapidly and robustly following hormone treatment compared to PR-B expressing cells. Our findings indicate that PR-A is a dominant driver of stem-like expansion in breast cancer cells. PR-A tumorspheres exhibited enriched ALDH+ and CD44+/CD24- populations compared to PR-B and promoted heightened gene expression of stem-like genes (e.g. FOXO1). We demonstrate that the PR target gene and co-activator FOXO1 promotes both PR-A and PR-B phosphorylation at Ser294 and augments tumorsphere formation. Direct inhibition of FOXO1 levels abrogates phospho-PR (Ser294) levels and tumorsphere formation in PR expressing cells. Finally, we show that Ser294 is required for PR-A induced expression of stem-like genes (e.g. FOXO1) and stem-like behavior as measured by ALDH+/CD44+ tumorspheres. Taken together, our data reveal unique functions of PR isoforms as modulators of distinct and opposing pathways (i.e. proliferation versus stem-like expansion) in luminal breast cancer models. A clear understanding of PR isoform-specific actions, phosphorylation events, and the role of co-factors such as FOXO1 may lead to novel biomarkers of advanced tumor behavior and reveal new approaches to pharmacologically target PR isoforms in luminal breast cancers.
Expression of the cocaine- and amphetamine-regulated transcript (CART) recruits SWI/SNF chromatin remodelling complexes to the estrogen receptor

Darran P O'Connor¹, Brian Mooney¹, Sudipto Das¹, Rut Klinger², Bruce Moran², Triona Ni Chonghaile¹, Gerard Cagney², Adrian Bracken³ and William M Gallagher². ¹Royal College of Surgeons in Ireland, Dublin, Ireland; ²University College Dublin, Dublin, Ireland and ³Trinity College Dublin, Dublin, Ireland.

Introduction
Cocaine- and amphetamine-regulated transcript (CART) peptides are neuropeptides involved in regulating physiological processes, such as feeding and drug reward. Recent studies have associated high CART expression with worse overall survival in patients with small-bowel carcinoid tumours and estrogen receptor-positive (ER+), lymph node-negative breast cancer. CART was also shown to be associated with poor patient response to tamoxifen, suggesting CART may play a role in conferring tamoxifen resistance.

Materials and methods
We have previously demonstrated that CART can impact the transcriptional activity of ERα through the use of western blotting and qPCR for specific ERα gene targets. RNA sequencing was carried out using a stable CART-inducible cell line model to identify genes which are upregulated/downregulated in cells expressing CART. Further, using our stable CART-inducible cell line model, we performed ERα-Immunoprecipitation followed by in-solution mass spectrometry to identify differentially recruited protein complexes +/- CART expression.

Results and discussion
RNA sequencing revealed 156 significantly downregulated, and 100 significantly upregulated, genes in cells expressing CART (p<0.05). Through mining of publicly available ERα ChIP-seq data sets, both upregulated and downregulated gene sets were found to contain genes which have previously been shown to contain ERα binding events within their promotor regions. Mass spectrometry analysis revealed that the majority of proteins recruited to ERα in the presence of CART were members of the SWI/SNF (BAF) chromatin remodelling complex. The identification of SMARCD1 within this complex was of particular interest to this study, as this protein has previously been reported to be a critical mediator of nuclear receptor function. Further in silico analysis demonstrated high expression of SMARCD1 correlates with poor overall survival (OS) (p<0.00001) and distant metastasis free survival (DMFS) (p=0.00708) in a cohort of ER+ breast cancer patients. Intriguingly, SMARCD1 expression did not correlate with poor OS or DMFS in a cohort of ER- breast cancer patients, suggesting that this negative impact on survival is dependent on ER status.

Conclusion
In conclusion, we suggest that CART expression results in the recruitment of chromatin remodelling complexes to ERα in order to facilitate the regulation of receptor function and this impacts on patient outcome.
Molecular cross-talk between retinoic acid and NOTCH1 signaling pathways: Role in triple negative breast cancer

Gabriela Paroni1, Adriana Zanetti1, Marco Bolis1, Arianna Vallerga1, Martina Troiani1, Maddalena Fratelli1, Mami Kurosaki1, Mineko Terao1 and Enrico Garattini1. 1Mario Negri Institute for Pharmacological Research, Milan, Italy.

Triple Negative Breast Cancer (TNBC) represents 10-20% of all breast cancers and it is characterized by poor prognosis and high recurrence rate. The heterogeneity of the disease and the absence of well-defined molecular targets have so far challenged successful therapeutic strategies. NOTCH1 has been found to act as a driver oncogene in a small subset of TNBC characterized by constitutive activation of the protein, acting as a transcription factor. Preclinical studies support an anti-tumor activity of All-Trans Retinoic Acid (ATRA) in specific subsets of breast cancer.

By screening a large panel of breast cancer cell lines recapitulating the heterogeneity of TNBC we identify a specific subset sensitive to the anti-proliferative activity of ATRA. These cell lines (N-TNBC cell lines) are characterized by a Notch1 intragenic fusion transcript conferring gain of function activity to the protein. Indeed, sequence analysis reveals that the cell lines harbor an interstitial deletion in the NOTCH1 gene encompassing the negative regulatory region (NRR) domain. These cell lines depend on Notch active signaling for their proliferation since their cell growth is impaired by Notch inhibitors (γ-secretase inhibitors, e.g. DAPT, PF-3084014). Proliferation assays reveal that ATRA and γ-secretase inhibitors act synergistically in inhibiting cancer cell growth in N-TNBC cell lines suggesting the existence of a cross talk between the molecular pathways engaged by retinoic acid and NOTCH1.

By using retinoic acid receptors (RARs) agonists and antagonists as well as RAR specific silencing experiments we identify RARα as the retinoic acid receptor responsible of the anti-proliferation activity of ATRA in N-TNBC cell lines. In particular N-TNBC cell lines respond to RARα activation by inducing high amounts of the onco-suppressor protein RARβ. This feature is unique in ATRA sensitive TNBC cell lines and does not occur in ATRA sensitive luminal cell lines arguing for the existence of a retinoic acid specific mechanism of action in N-TNBC. Since RARs act as transcription factors inside the cells, to gain insights into the molecular pathway at the basis of the observed ATRA/NOTCH1 cross talk, we performed RNAseq analysis of ATRA and/or DAPT treated N-TNBC cells. Gene set enrichment analysis reveal that ATRA is able to directly affect NOTCH1 transduction pathway by modulating the expression of NOTCH1 target genes. In particular, in two out of three N-TNBC cell lines ATRA directly inhibits the NOTCH1 expression at a transcriptional level and its downregulation is increased by ATRA/DAPT combinations. Pathway analysis has allowed the identification of putative molecular hubs responsible for the synergistic effects observed and therefore likely at the basis of the crosstalk between ATRA/NOTCH pathways. These findings are of clinical interest since both the retinoid and NOTCH signaling display crucial physiologic activities and their pleiotropic effects could impinge on the success of therapeutic options based on their pathway modulation.

The newly discovered specificity of ATRA action in the context of NOTCH1 addicted TNBC provides new tools for the identification of patients candidates benefitting from strategies targeting the ATRA/NOTCH axis.
Systemic perturbations induced by all-trans retinoic acid in the gene-expression profiles of sixteen breast cancer cell lines characterized by sensitivity and resistance to the anti-proliferative effects of the retinoid

Enrico Garattini¹, Marco Bolis¹, Arianna Vallerga¹, Maddalena Fratelli¹, Gabriela Paroni¹, Adriana Zanetti¹, Mami Kurosaki¹, Maurizio Gianni¹, Valentina Celestini¹ and Mineko Terao¹. Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy.

Background: All-trans retinoic acid (ATRA) is a promising agent in the treatment of breast cancer. In view of ATRA-based therapeutic strategies aimed at the personalized treatment of mammary tumors, we recently demonstrated that approximately 70% of estrogen-receptor-positive (ER⁺) breast cancer is sensitive to the anti-proliferative effects of ATRA (1). In contrast only 10-20% of the HER2-positive and triple-negative counterparts respond to the retinoid. On the basis of these data and the available basal gene-expression profiles of breast cancer cell lines and primary tumors, we developed a model consisting of 21 genes (ATRA-21) which correctly predicts ATRA-sensitivity in the context of breast cancer (2).

Aims and Approach: The present study is aimed at getting insights into the molecular mechanisms underlying the anti-tumor action of ATRA in the specific subsets of breast cancer identified. In addition, we intend to determine specific genes and gene-networks modulated by ATRA which may represent pharmacological targets for the design of rational combinations between the retinoid and unrelated therapeutic agents to be used in the personalized treatment of breast cancer. A final goal is the identification of potential bio-markers of the anti-tumor response to ATRA to be used in the clinics. To address all these points, we performed deep-sequencing experiments on a panel of sixteen cell lines recapitulating the heterogeneity of the breast cancer phenotype and characterized for their anti-proliferative response to ATRA

ATRA-score = ATRA sensitivity index, the higher the score the higher is the sensitivity to ATRA. ER⁺ = estrogen-receptor-positive cell line. HER2⁺ = Her2-positive cell line.

Results: We exposed each cell line to ATRA (1 µM) for 24 hours and extracted total RNA which was subjected to deep sequencing. The global gene-expression data were analyzed with a number of complementary bio-informatic tools which resulted
in the identification of approximately 100 genes whose expression is up- or down-regulated specifically in ATRA-sensitive luminal and/or basal cell lines. Pathway and gene-network analysis indicate a strong enrichment in the up-regulation of genes involved in the pathways modulated by interferons. These last results are consistent with the idea that ATRA exerts a strong immuno-modulatory action in breast cancer cells and represents proof of principle for the evaluation of combinations between the retinoid and check-point inhibitors in the treatment of breast cancer.

Estrogen receptor β suppresses metastasis of inflammatory breast cancer by regulating cell cytoskeleton and cytokine signaling

Christoforos Thomas¹, Ilias Karagounis¹, Ratnesh K Srivastava¹, Sushil Kumar¹, Jayashree Karar¹, Hann-Hsiang Chao¹, Adam Kazimierczak¹, Igor Bado³, Fotis Nikolos³, Nektaria Leli¹, Constantinos Koumenis¹, Savitri Krishnamurthy², Naoto T Ueno², Rumela Chakrabarti¹ and Amit Maity¹. ¹University of Pennsylvania, Philadelphia; ²The University of Texas MD Anderson Cancer Center, Houston and ³Baylor College of Medicine, Houston.

Inflammatory breast cancer (IBC) is the most lethal form of breast cancer that accounts for about 10% of breast cancer mortality annually in the US. Poor prognosis is largely due to the high propensity of IBC tumors to develop distant metastasis that occurs directly from the gland epithelium and through lymphatic invasion in which dermal lymphatics are filled with tumor emboli. Owing to the complex metastatic process, the molecular basis of IBC aggressiveness is poorly understood, and no specific therapeutic target has been identified. Despite the lack of estrogen receptor α (ERα) in the majority of IBC tumors, estrogen may still play a role in these cancers through pathways that involve ERβ. Our tissue staining reveals expression of ERβ in more than 50% of IBCs that is reproduced in IBC cell lines. Furthermore, analysis of IBC datasets indicates correlation of receptor expression with good prognosis. We studied this association in preclinical models of IBC by knocking out ERβ in IBC cells. This promotes migration and invasion through cytoskeleton remodeling whereas re-expression of the receptor in knockout cells restores the cytoskeletal structure and migration to the levels of control cells. Consistent with increased migration, deletion of ERβ activates large gene networks of cell de-differentiation and cytokine synthesis that trigger tumor microenvironment responses to promote the motile phenotype of IBC cells. In contrast, ligands that activate the receptor inhibit signaling that contributes to metastasis in IBC. Analysis of an orthotopic xenograft model shows that IBC tumors lacking ERβ have higher propensity for metastasis compared with the ERβ-proficient tumors supporting the anti-metastatic activity of the receptor. Our findings point towards a role of ERβ in preventing distant metastases by inhibiting dissemination of IBC cells and maintaining the integrity of emboli. This function combined with distinct expression indicates the potential of ERβ to represent a unique prognostic marker and therapeutic target that can be utilized to repress IBC metastasis and eliminate its associated mortality.
Clinical significance of androgen receptor expression in breast cancer

Nobuyuki Arima¹, Reiki Nishimura¹, Tomofumi Osako¹, Yasuhiro Okumura¹, Masahiro Nakano¹ and Mamiko Fujisue¹. 'Kumamoto Shinto General Hospital, Kumamoto, Japan.

Background
Breast cancer is highly heterogeneous and immunohistochemistry (IHC) is used to determine breast cancer subtypes using estrogen and progesterone receptor (ER and PgR), HER2 and Ki-67. The androgen receptor (AR) is frequently expressed in breast cancer, but evaluation of AR has not been standardized and the oncogenic activity in breast cancer is still unclear. The objectives of this study were to assess the clinical significance of AR expression in breast cancer patients with primary (pretreatment and posttreatment) and recurrent breast cancer in relation to breast cancer subtype.

Methods
Primary and recurrent breast cancer patients who underwent treatment from March 2017 to May 2018 were enrolled in this study. A total of 591 primary breast cancer cases and 52 recurrent cases were analyzed. Thirty-four primary cases received treatment before surgery. The factors investigated included nodal status, tumor size, nuclear grade, ER/PgR and HER2 status, p53 overexpression, and the Ki-67 index value. The AR expression was evaluated using IHC and the expression was divided into 3 groups; negative, low (<10%) and high (≥10%). Breast cancer subtypes were categorized based on the IHC data derived from ER/PgR, HER2 and Ki-67 (cutoff point: 20%) in invasive tumors.

Results
The AR expression rates were 69.7%(low: 33.9% and high: 35.8%) in all primary cases. Patients who received treatment before surgery had an AR rate of 38.2% which was significantly different from the untreated cases (p=0.002). In the cases with neoadjuvant chemotherapy, the positive rate significantly decreased after chemotherapy in the cases with non-pCR (pathological complete response). The positive rate of recurrent/metastatic cases was 57.7% (low: 34.6% and high: 23.1%). Higher AR expression significantly correlated with smaller tumor size, positive ER/PgR, lower Ki-67 values and nuclear grade and negative p53 overexpression. The AR expression rate was 72.5% in Luminal A, 73.2% in Luminal B, 80% in Luminal HER2, 56.8% in HER2 enriched and 43.5% in triple negative (TN) cases. Moreover, in the TN tumor cases, AR expression significantly correlated with postmenopausal status and a higher degree of malignancy determined by Ki-67, p53, and nuclear grade. However, there was no significant relationship between these factors and the other subtypes.

Conclusion
The AR expressions were higher in the primary breast cancer cases than in the pretreated and recurrent cases. The AR expression significantly correlated with a lower degree of malignancy and postmenopausal status only in the TN breast cancer cases. These findings suggest that the TN cases with AR-positive tumors have a more favorable prognosis compared with the cases with AR-negative tumors. However, further studies are needed to determine the predictive and prognostic factors for clinical use.
Progesterone drives ER-positive and triple negative breast cancer cell proliferation through progesterone receptor membrane component 1

Diego A Pedroza¹, Ramadevi Subramani¹, Adriana Galvez¹ and Rajkumar Lakshmanaswamy¹. ¹Texas Tech University Health Sciences Center El Paso Graduate School of Biomedical Sciences, El Paso, TX.

Introduction: The role of progesterone and its receptors in breast cancer progression continue to be studied but remain controversial. Progesterone membrane receptors with the ability to regulate kinase signals, mediating breast cancer proliferation have been demonstrated. Increased expression of the Progesterone Receptor Membrane Component 1 (PGRMC1), a heme – binding protein with the ability to interact and stabilize epidermal growth factor receptor (EGFR) is frequently found in breast cancer tissue. Some evidence suggests that progesterone can stimulate and regulate breast cancer cell proliferation. The basis of the signaling mechanisms by which Progesterone exerts its function remains largely unknown. Both the nuclear and membrane progesterone receptors could play a significant role in the development and progression of breast cancer and both could become viable therapeutic options. We, aim to investigate the role of PGRMC1 in progesterone driven breast cancers.

Materials and Methods: Human breast tissues were utilized to identify PGRMC1 expression along with a panel of normal and breast cancer cell lines. Two breast cancer cell lines (ZR-75-1 and MDA-MB-468) were selected and treated with progesterone and AG-205 (PGRMC1 inhibitor) at different concentrations to assess optimum dosage. We performed MTS assay, qRT-PCR, Western blot, immunofluorescence, immunohistochemistry and flow cytometry for measuring cell proliferation, apoptosis and key markers involved in these processes. We also performed an in silico analysis to compare the expression of PGRMC1 in various cell lines and breast cancer tissues.

Results: Immunohistochemistry demonstrated strong staining for PGRMC1 in human breast cancer tissue compared to normal tissue. Increased PGRMC1 expression was observed specifically in ZR-75-1 and MDA-MB-468 cells by qRT-PCR, western blot and immunofluorescence, these results were validated and compared to microarray-based gene expression analysis of breast cell lines and breast tumor data sets. Progesterone treatment increased cell proliferation in a dose dependent manner while AG-205 decreased cell proliferation in a dose dependent manner in ZR-75-1 and MDA-MB-468. Minimal effects of AG-205 were observed in normal breast epithelial cells. AG-205 also, induced apoptosis in both ZR-75-1 and MDA-MB-468 cell lines. Furthermore, short-term treatment of progesterone increased both mRNA and protein expression of PGRMC1. Key markers of cell proliferation (pAKT, CCND1, pEGFR, pmTOR) and apoptosis (PTEN, Bcl2, Bax, Bim) revealed that PGRMC1 facilitated the proliferative effect of progesterone. Interestingly progesterone increases phosphorylation of EGFR and treatment of AG-205 alters EGFR expression in a dose dependent manner.

Conclusion: Our data demonstrates that PGRMC1 plays a prominent role in regulating progesterone driven cell proliferation in both ER-positive and triple negative breast cancer cells. These initial findings uncover the potential of PGRMC1 as a therapeutic target for breast cancers.
Quantitative combinatory indexed ChIP-seq reveals distinct transcriptional complexes containing estrogen receptor and GREB1 at chromatin in breast cancer cells

Jun Sun¹ and Marc E Lippman¹. ¹University of Miami, Miami, FL.

GREB1 is an estrogen-activated gene in estrogen receptor α (ER)-positive breast cancer cells. GREB1 is also required for estrogen-stimulated breast cancer cell growth and its level is highly correlated to ER level in breast cancer cells and tumor samples. In endocrine resistant diseases, GREB1 is often dysregulated. GREB1 has been shown to interact with ER and bind to the same ER binding sites throughout the genome. There is no identified functional domain in GREB1 and it is not completely known how GREB1 exerts its function to regulate the transcription of ER target genes. In order to demonstrate whether GREB1 is present in the ER-containing transcriptional complex at chromatin, we have adapted and developed a quantitative combinatory indexed ChIP-seq assay suitable for dissecting components in a transcriptional cofactor complex in a genome-wide scale. In ER-positive MCF-7 breast cancer cells, we found that almost all GREB1 binding sites are the same sites bound by ER or its bona fide coactivator SRC-3. We further found that GREB1 and SRC-3 are both present in the same ER-containing complex at chromatin. Thus, both GREB1 and SRC-3 are integral members of the ER transcriptional complex at chromatin. Moreover, we discovered that only a portion of GREB1 at chromatin is present in the ER complex while the other portion of GREB1 is present in a different complex lacking ER or SRC-3 at the same genomic loci. Thus, two distinct GREB1-containing complexes are identified in equilibrium at chromatin: one contains ER/SRC-3 and the other one lacks ER/SRC-3. Our results suggest a non-traditional role of GREB1 in transcriptional regulation of ER target genes. The method used in our study can be widely applied for probing components of transcriptional complexes at chromatin.
Pregnancy inhibits mammary carcinogenesis by persistently altering the hypothalamic-pituitary axis

Ramadevi Subramani\textsuperscript{1}, Adriana Galvez\textsuperscript{1}, Diego Pedroza\textsuperscript{1} and Rajkumar Lakshmanaswamy\textsuperscript{1}. \textsuperscript{1}Texas Tech University Health Sciences Center El Paso, El Paso, TX.

Pregnancy, carried to term at an early age, is probably the best natural protection against breast cancer development. The relative life-long breast cancer risk for women that give birth to their first child before the age of 20 years is approximately half that of nulliparous women. In contrast, if a woman undergoes her first full-term pregnancy after the age of 35, her risk for breast cancer is increased even more than nulliparous women. In the current generation many women are career oriented and have children later in life. Universally the average age at first birth is on the rise. It is critical to understand the underlying mechanism of this protective effect of pregnancy against breast cancer to develop novel prevention strategies to reduce the risk of breast cancer without women having to undergo pregnancy early in life. Earlier, we and others have demonstrated that post-pregnancy there were persistent changes in circulating levels of hormones. In order to understand the significance of these systemic changes we determined alterations in the hypothalamic-pituitary axis in parous rats. In particular, we examined the static and dynamic alterations in the hypothalamic-pituitary axis in response to pregnancy. Seven weeks old female Lewis rats were injected with the chemical carcinogen N-methyl-N-nitrosourea (MNU) at a dose of 50mg/kg body weight intraperitoneally. Two weeks post-carcinogen treatment these rats were housed with a male rat. On the observation of the vaginal plug the male was removed from the cage. Once the rats gave birth they nursed the pups for three weeks and were weaned after that period. Mammary tumorigenesis was monitored through weekly palpation for a period of nine months. A subset of rats at 6, 12 and 24 weeks post-weaning were used to study static and dynamic changes in the level of hormones. We investigated the static alterations in the hypothalamic-pituitary axis in response to pregnancy by measuring the levels of thyrotropin releasing hormone (TRH), growth hormone releasing hormone (GHRH), somatostatin (SS), dopamine (DA), growth hormone (GH) and prolactin (PRL). Next we investigated if the dynamic alterations in the hypothalamic-pituitary axis in response to pregnancy. Control and parous animals were subjected to secretogogue treatments (Growth Hormone Related Peptide 6 for GH and Perphenazine for PRL) and the levels of GH and PRL were measured. We also isolated the pituitary and treated them with the secretogogues and measured the levels of GH and PRL. Our data demonstrated that pregnancy resulted in persistent static and dynamic alterations in circulating levels of hormones. Parous rats response to the secretogogues was severely blunted compared to the control nulliparous rats. The levels of TRH, GHRH, GH and PRL were significantly lowered in parous rats while DA and SS levels were higher in nulliparous rats. As expected mammary carcinogenesis was significantly inhibited in parous rats. Overall, these preliminary results suggest that pregnancy induces persistent changes in hypothalamic-pituitary axis, which results in a lowered hormonal promotion environment resulting in inhibition of mammary carcinogenesis.
Role of estrogen receptor alpha acetylation in estrogen-dependent gene regulation in breast cancers

Yasmin M Vasquez1, Rohit Setlem1, Shino Murakami1 and W Lee Kraus1. 1UT Southwestern Medical Center, Dallas, TX.

Estrogens, such as 17β-estradiol (E2), act through estrogen receptor alpha (ERα), a ligand-regulated transcription factor that binds across the genome to promote enhancer formation and regulate gene expression. ERα is expressed in approximately 70% of breast cancers, where it regulates the transcription of genes involved in mitogenic and inflammatory pathways. We are exploring the the acetylation of ERα on lysines 266 and 268, a modification that enhances the DNA binding and transcriptional activities of ERα. ERα acetylation is catalyzed by the lysine acetyltransferases p300 and CBP in an E2- and steroid receptor coregulator (SRC)-dependent manner. Acetylation-dependent activation of ERα has potential implications in breast cancers associated with enhanced coregulator interactions, such as SRC-3/Amplified in Breast (AIB1) gene amplifications and gain-of-function ERα mutations in endocrine resistant metastatic tumors, such as Y537S and D538G. Increased association of ERα with SRCs and p300/CBP leading to enhanced ERα acetylation may promote gain-of-function ERα activity. Our hypothesis is that acetylation of ERα alters its function by increasing E2-responsive gene transcription and signaling in breast cancers. Our current efforts are focused on investigating the role of ERα acetylation on chromatin binding and accessibility, enhancer activity, and target gene transcription. We are using the ER-positive MCF-7 breast cancer cell line with a knockdown/re-expression strategy with biochemical mimics of acetylated (K266/268Q) or unacetylated (K266/268R) ERα. Genomic ERα binding profiles using chromatin immunoprecipitation-sequencing (ChIP-seq) has defined overlapping, but unique, sets of transcriptional targets and recruitment kinetics for the ERα mutants. Current efforts are focused on defining global transcriptional responses associated with the unique binding activities using precision run-on sequencing (PRO-seq). Ultimately, our goal is to define how acetylation affects the binding of ERα to chromatin and its effect on the transcriptional activity of E2-target genes in breast cancers in the context of gain-of-function ERα mutations and coregulator amplifications. Supported in part by a postdoctoral fellowship from the Lalor Foundation to YMV, and grants from the NIDDK, NICHD, and CPRIT to WLK, as well as support from the Cecil H. and Ida Green Center for Reproductive Biology Sciences Endowment.
Distinctive coding and non-coding RNA profiles of pre-menopausal and post-menopausal benign breast

Jodi M Carter1, Asha A Nair1, Jaime I Davila1, Ethan P Heinzen1, Tanya L Hoskin1, Stacey J Winham1, Derek C Radisky2, Amy C Degnim1 and Daniel W Visscher1. 1Mayo Clinic, Rochester, MN and 2Mayo Clinic, Jacksonville, FL.

Background: Despite a paucity of data on the benign breast transcriptome, reduction mammoplasty tissue is commonly used as a control for RNA biomarker discovery in breast cancer (BC). We evaluated the transcriptome of benign breast to characterize pre-menopausal and post-menopausal coding and non-coding RNA profiles. These profiles will provide insight into the metabolic landscape of benign breast and inform transcriptomic studies of BC and peri-tumoral microenvironments.

Methods: With institutional approval, cryobanked fresh breast tissues from reduction mammoplasties (age 15-62y; follow-up: 4-10 y with no cancer events), with histologically-confirmed benign tissues with similar epithelial: stromal tissues were grouped into 4 age sets (< 30y, N=10; 30-39y, N=11; 40-49y, N=10; ≥50y (clinically post-menopausal), N=10). Following RNA extraction, library preparation (Illumina TruSeq Stranded mRNA kit), and sequencing (Illumina HiSeq 4000), reads were processed (MAP-RSeq v3.0.0) and aligned (STAR aligner; hg38). Differential expression (DE) analysis (edgeR 2.6.2) identified DE genes from normalized RPKM reads (absolute log2 fold change (FC) > 1 and false discovery rate (FDR) < 0.10), corrected for intra-group biases using medians (absolute FC cut-off of >1.5). Over-representation analysis [Ingenuity pathway analysis (IPA), Ingenuity® Systems] and gene set enrichment analysis [(GSEA), GeneTrail 2.0] identified significantly-enriched pathways.

Results: Across the 4 age sets, 561 DE genes were identified. Compared to the post-menopausal (PM) set, the number of DE genes was highest in <30 y set (N= 372) and decreased with increasing age (N= 170, age 30-39 set and N=20, age 40-49 set), generating up-regulated (PM\text{up}) and down-regulated (PM\text{down}) PM transcriptomic profiles. The top PM\text{down} DE genes included RANKL, WNT4, MKI67, extracellular matrix, and lactation-related genes (lactoferrin ,MUC4, MUC16, p < 0.01). Top PM\text{down} canonical pathways were cell cycle-related (CDK1, CCNA2, CCNB2, ESPL1, TOP2A)(p< 0.001). Top PM\text{up} genes included those involved in adipogenesis, NPY1R, NPY2R, unsaturated fatty acid synthesis and eicosanoid signaling (P< 0.001). Top PM\text{up} canonical pathways included acyl co-A hydrolysis, stearate biosynthesis, acute phase response and RXR signaling (P < 0.001). GSEA of the entire gene set (N=15,466; ranked in order of 561 DE genes) identified 16 significant pathways, functionally grouped as mitochondrial energy metabolism, proteasome, and unsaturated fatty acid biosynthesis and signaling (PPAR pathway). While coding RNAs comprised 85% of DE transcripts, IncRNA comprised ~5%. Top DE IncRNAs and precursor miRNAs included MEG3, a tumor suppressor, LIN00092, miR22 and miR1182 (p < 0.0001).

Conclusions: Pre and post-menopausal benign breast tissues have distinctive transcriptomic profiles. PM benign breast has down-regulated proliferation/cell-cycle-related pathways, and up-regulated genes in mitochondrial energy pathways, lipogenesis and inflammatory pathways. Notably, many of the top DE coding and non-coding RNAs in PM benign breast have been implicated in BC progression, highlighting their value in better understanding breast carcinogenesis and the need to characterize their functional roles in normal aging and menopause.
Organochlorine pesticide residues in human breast tissue and their relationships with clinical and pathological characteristics of breast cancer

Rachel E Ellsworth¹, Paul J Kostyniak², Lai-Har Chi², Craig D Shriver¹, Nicholas S Costantino³ and Darrell L Ellsworth⁴. ¹Murtha Cancer Center, Bethesda; ²State University of New York at Buffalo, Buffalo; ³Windber Research Institute, Windber and ⁴4E-squared Genomic Solutions, Johnstown.

Agricultural pesticides are abundant environmental contaminants worldwide, prompting interest in studying their possible detrimental health effects. We examined organochlorine residues by quadrant (n = 245) in breast adipose tissues from 51 women with various stages of breast health to determine patterns of bioaccumulation within the breast and to assess relationships with patient clinical characteristics. Three organochlorine residues — 2,2-bis(p-chlorophenyl)-1,1-dichloroethylene (p,p′-DDE), hexachlorobenzene (HCB), and mirex — assayed by high resolution gas chromatography were abundant in breast tissue. p,p′-DDE (745 ± 1054 ng/g lipid) was the most prevalent residue, comprising 97.5% of the total chemical burden. Mean levels of p,p′-DDE and HCB were significantly correlated ($P < 0.001$) with patient age at mastectomy, and levels of p,p′-DDE were correlated ($P < 0.05$) with BMI. Pesticide concentrations did not differ significantly by breast quadrant and were not different in the quadrant(s) where the primary tumor was located compared to other cancer-free quadrants. In invasive cancer patients, organochlorine levels differed significantly based on clinical characteristics of the primary carcinoma, including stage, grade, ER status, and HER2 status, indicating that body burden of organochlorines may influence the development of specific subtypes of breast cancer. Potentially carcinogenic organochlorines were present at high levels within the human breast warranting further research to determine the impact of organochlorines in the etiology of breast cancer.

Computational scoring of tumor infiltrating lymphocytes in triple-negative breast cancer

Mohamed Amgad¹, Anindya Sarkar², Chukka Srinivas³, Rachel Redman³, Simrath Ratra², Charles J Bechert³, Benjamin C Calhoun⁴, Karen Mrazeck⁴, Uday Kurkure², Lee AD Cooper¹ and Michael Barnes³. ¹Emory University School of Medicine, Atlanta, GA; ²Roche Tissue Diagnostics, Digital Pathology, Mountain View, CA; ³Roche Diagnostics Information Solutions, Belmont, CA and ⁴Robert J. Tomsich Pathology and Laboratory Medicine Institute, Cleveland Clinic, Cleveland, OH.

**Background:** Stromal Tumor Infiltrating Lymphocytes (sTILs) are an established prognostic feature in triple-negative breast cancer, yet manual assessment or visual estimation of sTILs with conventional light microscopy may be subject to inter-pathologist variability. Recently published guidelines by the International TIL Working Group help address inter-pathologist variability, yet there remains a need for more objective and quantitative computational sTIL scoring.

**Methods:** Our study used 120 triple-negative breast cancer slides (one slide per patient). A deep-learning based image analysis workflow is used to perform segmentation and classification of tissue regions and cells on the digital whole slide image. We used 14 annotated slides to train and validate the deep learning model, and to obtain image segmentation and classification accuracy statistics. Non-training slides were used to evaluate the concordance of manual (m-sTIL) and computationally derived (c-sTIL) scores. To generate data to create the model we manually annotated tissue regions in FFPE H&E stained digital slides, including: tumor, stroma, and necrosis. Initial classification of cell nuclei was performed using a semi-automated image analysis method, and then manually corrected to generate ground truth for tumor, stroma (fibroblasts), and lymphocytes. All annotations were performed by a trained research fellow and reviewed by a board-certified pathologist. Corresponding region and nucleus-level annotations were combined to train and validate a fully-convolutional neural network that jointly classifies tissue regions and cell nuclei. Tissue region segmentation accuracy was assessed by the Dice coefficient to measure degree of overlap between predicted tissue regions and ground truth annotations. Cell classification accuracy was assessed using area under curve (AUC). Two board-certified pathologists independently generated an m-sTIL score for all slides according to clinical guidelines, and discrepancies between pathologists were resolved by consensus. c-sTIL scores were calculated as the percentage of classified stromal areas occupied by nuclei classified as lymphocytic infiltrates.

**Results:** Tissue region segmentation was accurate for both stroma (0.77 Dice) and tumor (0.83 Dice) regions, and accurate overall (0.78 Dice). Cell classification was highly accurate for lymphocytes (0.89 AUC), tumor cells (0.90 AUC), stromal cells (0.78 AUC), and overall (0.89 AUC, micro average). Inter observer spearman correlation between the m-sTIL scores of our two pathologists was 0.66 (p < 0.001). By comparison, the correlation between c-sTIL and consensus m-sTIL was higher at 0.73 (p < 0.001). Dichotomizing at a threshold sTIL score of 10%, c-sTIL scoring identifies low-sTIL patients with an accuracy of 85%. High- and Low- sTIL score patient groups show clear separation on a Kaplan-Meier curve for both c-sTIL and m-sTIL scoring approaches.

**Conclusions:** Our pipeline quantifies stromal TILs with high concordance with manual pathologist scores, and sheds light on the ability of computational approaches in standardizing diagnostic pathology workflows. Future work will investigate how other computationally driven histology biomarkers can predict outcomes and help prognosticate breast cancer patients.
Normal breast stromal fibroblast interaction with human ER+ breast cancer cells create an IL1β-enriched environment that suppresses normal breast progenitor proliferation while promoting cancer cell growth

Sumanta Chatterjee, Alexei Berdnikov, Edward Buchel, Janice Safneck, Aaron J Marshall, Leigh C Murphy and Afshin Raouf. 1Faculty of Health Sciences, University of Manitoba, Winnipeg, MB, Canada; 2Research Institute of Oncology & Hematology, CancerCare Manitoba, Winnipeg, MB, Canada and 3Section of Plastic Surgery, Faculty of Health Sciences, University of Manitoba, Winnipeg, MB, Canada.

Previous studies suggest that cancer-induced activation of stromal fibroblasts is an early event in tumour progression by promoting cancer cell proliferation through secretion of various cytokines. However, the nature of breast cancer cell interaction with the normal stromal fibroblasts is not clear and their role in tumour progression remains controversial. In particular, the role of fibroblasts as a major component of tumor niche in supporting ER+ tumour cell proliferation remains unexplored due to the lack of protocols to maintain and expand primary human ER+ breast cancer cells in vivo and ex vivo. In this study, we used a modified patient-derived organoid culture system and demonstrate that constitutively secreted cytokines from normal breast tissue fibroblasts specifically initiate a paracrine signaling mechanism with primary human estrogen receptor positive (ER+) breast cancer cells (ER+BC) which results in creation of an IL1b-enriched microenvironment. This paracrine crosstalk is initiated with constitutively secreted cytokines (IL6, IL8, CCL7) by the normal breast fibroblasts that result in PDGF-BB production in ER+ breast cancer cells but not in the normal breast epithelial cells. We further show that IL1b prevents the proliferation of normal breast epithelial progenitors while at the same time it promotes breast cancer cell proliferation. Moreover, we found that this new paracrine signaling mechanism is shared between normal and activated tumour-associated fibroblasts. Interestingly, we observed that in reconstructed tumour microenvironment in organoid cultures initiated with primary human ER+BC, tumour-associated fibroblasts and tumour-infiltrating immune cells obtained from the same original tumour sample, ER+BC show significantly enhanced proliferation and are less sensitive to anti estrogens such as tamoxifen. However, tamoxifen is more effective in reducing tumour cell proliferation when our newly identified paracrine crosstalk between fibroblasts and ER+BC (IL1b and PFGF-BB) signaling is blocked. Our observations then suggest that ER+ tumour cells could create a growth-promoting environment without activating stromal fibroblasts. Taken together, our findings suggest that in patients who undergo breast conserving surgeries, normal fibroblasts could be a significant modulator of tumour recurrence by enhancing proliferation of residual breast cancer cells in the tumour-adjacent breast tissue. Finally, our results suggest that patients diagnosed with malignant ER+ breast cancer could potentially benefit from combination therapy consisting of IL1bReceptor and PDGF Receptor blockers to enhance effectiveness of endocrine therapies such as tamoxifen.
Small molecule inhibition of smoothened in triple negative breast cancer-associated fibroblasts depletes cancer stem cells and sensitizes to cytotoxic chemotherapy in mice and humans

Alexander Swarbrick¹,², Aurelie Cazet¹,², Mun Hui¹,², Sandra O’Toole¹,², Elgene Lim¹,² and Miguel Martin³. ¹Garvan Institute of Medical Research, Darlinghurst, NSW, Australia; ²St Vincents Clinical School. UNSW, Darlinghurst, NSW, Australia and ³Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain.

The cellular and molecular basis of stromal cell recruitment, activation and crosstalk in carcinomas is poorly understood, limiting the development of targeted anti-stromal therapies. In mouse models of triple negative breast cancer (TNBC), we use single cell genomics to show that Hh ligand produced by neoplastic cells reprograms cancer-associated fibroblast (CAF) gene expression, driving tumor growth and metastasis. Hh-activated CAFs upregulated expression of FGF5 and deposition of fibrillar collagen, leading to FGFR and FAK activation in adjacent neoplastic cells and the acquisition of a stem-like, drug-resistant phenotype. Treatment with smoothened inhibitors (SMOi) reversed these phenotypes. Stromal treatment of TNBC patient-derived xenograft (PDX) models with SMOi downregulated the expression of cancer stem cell markers and sensitized tumors to docetaxel, leading to markedly improved survival and reduced metastatic burden.

In the phase I clinical trial EDALINE, 3 patients with metastatic TNBC derived clinical benefit from combination therapy with the SMOi Sonedigib and docetaxel chemotherapy, with one patient experiencing a complete radiological response. Responders also exhibited high baseline FGFR activation and ECM deposition, suggesting a mechanism of action consistent with findings from the animal models. These studies identify Hh signaling to CAFs as a novel mediator of cancer stem cell plasticity and drug resistance and an exciting new therapeutic target in TNBC.
Isolation and characterization of colony forming cells from primary malignant human breast cancer tumours

Sumanta Chatterjee\textsuperscript{1,2}, Pratima Basak\textsuperscript{1,2}, Susanna Tan\textsuperscript{3,4}, Sylvain Lefort\textsuperscript{3,4}, Davind Pellacani\textsuperscript{3,4}, Janice Safneck\textsuperscript{1}, Edward Buchel\textsuperscript{5}, Samuel Aparicio\textsuperscript{3}, Connie J Eaves\textsuperscript{3,4} and Afshin Raouf\textsuperscript{1,2}. \textsuperscript{1}Faculty of Health Sciences, University of Manitoba, Winnipeg, MB, Canada; \textsuperscript{2}Research Institute of Oncology & Hematology, CancerCare Manitoba, Winnipeg, MB, Canada; \textsuperscript{3}Terry Fox Laboratory, British Columbia Cancer Agency, Vancouver, BC, Canada; \textsuperscript{4}University of British Columbia, Vancouver, BC, Canada and \textsuperscript{5}Section of Plastic Surgery, Faculty of Health Sciences University of Manitoba, Winnipeg, MB, Canada.

Advances in imaging technologies and new therapies have increased the 5-year survival of breast cancer patients to ~80%, but metastatic relapses continue to make this malignancy the leading cause of death in women. Recent data suggest that relapses arise from the activated proliferation of malignant clonogenic cells that are therapy-resistant. However, direct characterization of these malignant clonogenic cells has been hindered due to a lack of methodology to isolate them from primary breast tumours and to maintain them in culture. We now report the development of two robust culture systems that allow primary malignant human breast cancer cells to be propagated \textit{ex vivo} at clonal densities and with retention of their tumorigenic potential as assessed in transplanted immunodeficient mice. Using the first set of culture conditions, we found that colony-forming cells (T-CFCs) could be detected at frequencies of 0.2-0.5% in 14 primary tumor samples and these included 9 ER+, 4 HER2+, and 1 triple negative breast cancers. The colonies generated had one of two distinct types of morphology and cytokeratin expression. Type A colonies stained positively for CK8/18 only and were obtained primarily from ER+ breast cancers. Type B colonies stained for CK14 only and were most frequently present in HER2+ and triple-negative breast cancers. Type A and B T-CFCs could be separately isolated based on their differential expression of CD49f (α6-Integrin) and the Epithelial Cell Adhesion Molecule (EpCAM); T(A)-CFCs being CD49f\textsuperscript{-}EpCAM\textsuperscript{+} and T(B)-CFCs being CD49f\textsuperscript{+}EpCAM\textsuperscript{-}. We also identified culture conditions that enable T-CFC expansion. Using this second system, we expanded 14 primary breast cancer tumours up to 5 passages in 2D and 3D organoid cultures. These \textit{ex vivo} expanded breast cancer cells (Exp-BCCs) contained both type A and type B T-CFCs and were detectable at much higher frequency (20-fold) than in the primary tumours. These Exp-BCCs produced ER+, or HER2+, or triple-negative breast cancer tumors in transplanted immunodeficient mice within 7 weeks, indicative of their retained malignant properties. We have also found that T-CFCs are less sensitive to chemotherapies than the non-CFCs in the primary tumours. These systems now offer consistent and powerful methods to isolate and characterize the cells in primary human breast cancers that are implicated as responsible for relapse.
Obesity, adipose inflammation, and race in patients with early stage breast cancer

Neil M Iyengar1, Beth Siegel2, Manmeet Malik2, Dilip D Giri1, Jacqueline Tsai3, Melissa Hughes2, Asif Adam2, Samantha Williams1, Xi K Zhou1, Williams Rodgers2, Paula Ginter3, Ami Patel2, Feng Yong2, Ajini Cherian2, Phyllis August2 and Andrew J Dannenberg3.
1Memorial Sloan Kettering Cancer Center, New York, NY; 2New York Presbyterian Hospital Queens, New York, NY and 3Weill Cornell Medicine, New York, NY.

**Background:** Elevated body mass index (BMI) is associated with increased risk of estrogen receptor-positive postmenopausal breast cancer. Mechanistically, most individuals with elevated BMI have breast white adipose tissue inflammation (WATi) which confers increased breast cancer risk, particularly in those with existing benign breast disease. Individuals with WATi have elevated in-breast expression of aromatase and several systemic changes that increase breast cancer risk, including hyperinsulinemia and higher levels of C-reactive protein. However, women with normal BMI but high levels of body fat are also likely to harbor WATi and are at increased risk of postmenopausal breast cancer. The accuracy of BMI for assessing adiposity and predicting obesity-related disorders, including cancer, varies across race and ethnicity. Whether the association between BMI and WATi varies by race is unknown. Here we aimed to characterize relationships among breast WATi and clinicopathologic features in a racially diverse cohort undergoing mastectomy for breast cancer treatment.

**Methods:** Non-tumorous breast tissue and fasting blood were collected from women undergoing mastectomy for breast cancer treatment or prevention at a single center serving a racially diverse patient population. Breast WATi was detected by the presence of crown-like structures in the breast (CLS-B), which are composed of a dead/dying adipocyte surrounded by CD68+ macrophages. Clinicopathologic data were abstracted from electronic medical records. Associations among categorical variables were examined using Fisher's exact test. Relationships between continuous variables were examined using the Spearman correlation.

**Results:** As of May 18, 2018 62 patients have been accrued; median age 55 (range 32 to 84). Self-reported race distribution was: 36 (58%) Asian, 5 African American (8%), 20 (32%) Caucasian, and 1 (2%) unknown. Breast tissue has been analyzed for WATi in 60 cases thus far. Clinicopathologic features stratified by the presence or absence of breast WATi are presented in [table1]

Breast WAT inflammation was associated with obesity (P=0.02) and a trend to association was observed with dyslipidemia (P<0.09).

**Conclusions:** Breast adipose inflammation is associated with elevated BMI and possibly metabolic syndrome disorders in a racially diverse population. These findings are consistent with observations from predominantly Caucasian cohorts. Race-specific characteristics will also be examined. Study accrual is ongoing and updated results will be presented.
Investigating breast cancer dormancy in response to microenvironment cues with well-defined synthetic extracellular matrices

April M Kloxin1, Elisa M Ovadia1, Lina Pradhan1 and Lisa A Sawicki1. 1University of Delaware, Newark, DE.

Breast cancer recurs in approximately 20% of disease-free patients 5+ years after successful treatment of the original tumor. These late recurrences often occur at metastatic sites, including the bone marrow and lungs, and are hypothesized to arise from disseminated tumor cells (DTCs) that reactivate after a long period dormancy. Interactions between DTCs and the microenvironment at these sites are thought to be important regulators of both breast cancer cell dormancy and reactivation. New approaches are needed to study this complex process and test hypotheses about key cell-microenvironment interactions in dormancy toward improved treatment strategies.

In this work, we investigated the role of cell-matrix and cell-cell interactions on dormancy and activation of breast cancer cells utilizing well-defined materials to mimic the extracellular matrix (ECM) of metastatic sites and selectively introducing metastatic niche cells via dynamic co-culture. We established synthetic ECMs with well-defined properties that mimicked key aspects of the mechanical properties and biochemical content of bone marrow and lung metastatic sites (Young's modulus E~0.5-5 kPa, respectively, and rich in collagen). These synthetic ECMs were constructed with a bioinert, multifunctional poly(ethylene glycol) crosslinked with a cell-degradable peptide and decorated with integrin-binding peptides derived from collagen and laminin, creating three-dimensional (3D) environments for the culture of breast cancer cells and niche cells. We cultured breast cancer cells of different metastatic potential (estrogen receptor positive [ER+, T47Ds] and triple negative [ER-, MDA-MB-231s]) within matrices, with or without co-culture of niche cells, and examined differences in markers of dormancy for up to 6 weeks.

Both breast cancer cell types exhibited good viability in 3D culture (> 90%). Different degrees of cell proliferation (metabolic activity, EdU assay, cell/cluster number and volume) were observed over the first 2 weeks in culture, dependent upon matrix composition. Interestingly, ER- MDA-MB-231s were more responsive to differences in the biochemical content of the matrix, with increased elongation and proliferation observed within collagen mimic environments, whereas fewer differences were observed in the responses of the ER+ T47Ds to these same compositions. Further, both cell types exhibited significant decreases in proliferation in response to increased matrix density, mimicking the moduli of bone marrow to lung tissues. Dormant single cells or small cell clusters, reminiscent of micrometastases, were observed over weeks 2-6. Immunostaining and bioinformatics analyses revealed increased expression of autophagy markers for these dormant cells, suggesting a potential mechanism of survival. Additionally, co-culture with specific niche cells, including human mesenchymal stem cells and osteoblasts, was observed to enhance or suppress breast cancer cell proliferation within these well-defined environments. These studies have established a new controlled 3D breast cancer dormancy culture model, with on-going investigations examining cell re-activation for the identification of therapeutics to maintain dormancy and prevent recurrence.
The immune microenvironment of ductal carcinoma in situ of the breast

Nami Yamashita¹, Yuichi Hisamatsu¹, Tomoko Shigechi¹, Eriko Tokunaga², Hiroshi Saeki¹, Eiji Oki¹ and Yoshihiko Maehara³.
¹Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; ²National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan and ³Kyushu Central Hospital of the Mutual Aid Association of Public School Teachers, Fukuoka, Japan.

Background: The importance of tumor-infiltrating lymphocytes (TIL) in invasive breast carcinoma for tumor development and therapeutic response is widely accepted. However, the immune microenvironment of breast ductal carcinoma in situ (DCIS) has not been fully elucidated. Evasion of immune surveillance is a necessary step in tumor evolution. In DCIS, the tumor cells are relatively protected from the immune system due to an myoepithelial cell layer and basement membrane, and intraductal immune cells are rarely detected. In contrast, in invasive disease, cancer cells and immune cells are often intermingled. Thus, understanding the immune microenvironment of in situ to invasive carcinoma transition might be particularly important to identify novel targets for early stage of tumor invasion.

Aims: The aim of this study is to evaluate the clinical importance of TILs in DCIS.

Methods: TILs were assessed in 133 DCIS samples with or without microinvasive disease according to the proposed method from the International Immuno-Oncology Working Group on Breast Cancer. In addition, the relationship between TILs in DCIS and clinicopathological features was evaluated.

Results: TILs are present in most DCIS in varying levels. The median proportion of TILs in DCIS was 14%. Only a minority of DCIS showed >50% TILs, which represented only 12.8% of all cases. High TILs in DCIS was significantly associated with comedo necrosis (p<0.0001), high nuclear grade (p=0.0030), ER negativity (p<0.0001), PR negativity (p<0.0001), HER2 positivity (p=0.0030). Triple negative DCIS and HER2 positive DCIS had significantly higher level of TILs (p=0.0008). No correlation was demonstrated between TILs and recurrence risk.

Conclusions: High TILs in DCIS was significantly associated with adverse histopathologic features. Further characterization of immune environment of DCIS may be essential for immunotherapy and breast cancer prevention.
The prognostic significance of estrogen formation as a consequence of aromatase expression in tumor microenvironment

Tae Hyun Kim1, Anbok Lee1, Jae Woong Han1, Soo Jin Jung1 and Kyung-Do Byun2. 1Inje University, Busan Paik Hospital, Busan, Republic of Korea and 2Dong-A University Hospital, Busan, Republic of Korea.

Estrogen synthesis via aromatase in adipose tissue has an important role in progression of postmenopausal breast cancer. The increased local concentrations of estrogen in breast cancer via aromatase overexpression within the tumor tissue have been demonstrated by some investigators. Although aromatase inhibitor is the standard endocrine therapy for postmenopausal breast cancer patients, it is not uncommon for patients to have poor compliance to the drugs due to their side effects. This research is based on the hypothesis that if aromatase expression is related to prognosis and if therapeutic effect varies depending on the degree of aromatase expression, then this study may be able to suggest a new guideline in terms of choosing between aromatase inhibitors and tamoxifen.

Methods: 154 postmenopausal breast cancer patients who underwent surgery and aromatase inhibitor therapy in Busan Paik Hospital, Inje University from January 2005 to December 2010 were enrolled. Patients with DCIS or stage IV breast cancer were excluded. Patients' clinicopathological data were collected and TMA blocks were created for immunohistochemistry studies to examine aromatase expression.

Results: The recurrence has occurred in 7 patients (6.9%). Stage, tumor size and number of lymph node metastasis were related to increased risk of recurrence (p=0.051, 0.043, 0.001). The aromatase expression in cancer cells had significant correlation with clinical stage (p=0.041). There was also a positive correlation between Ki67 and aromatase expression in cancer tissue (p=0.006).

However, aromatase expression in cancer, stromal, and adipose tissue had no relationship with recurrence (p=0.410, 0.627, 0.552).

Conclusions: Aromatase expression in cancer cells was correlated with clinical stage. This implies that aromatase expression might have a role of prognostic marker in addition to role of treatment indicator. There was no direct correlation between aromatase expression and recurrence.
Transcriptome alteration of breast cancer cells in the process of tumor-associated macrophages-promoted metastasis

Meijun Long1,2,3, Mei Yang2, Jun An1, Hang Su3 and Renbin Liu1. 1The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China; 2The Second Xiangya Hospital, Central South University, Changsha, Hunan, China and 3The University of Texas Health Science Center at San Antonio, San Antonio, TX.

Introduction: Tumor-associated macrophages (TAMs) play an important role in the process of tumor metastasis. Previous studies have shown that TAMs induce breast cancer cells undergo epithelial-mesenchymal transition (EMT) by secreting CCL18. Reciprocally, the induced mesenchymal-like breast cancer cells activate macrophages into a TAM-like phenotype via secreting the cytokine granulocyte-macrophage colony stimulating factor (GM-CSF), forming a positive feedback loop that is essential to breast cancer metastasis.

Methods: To better understand the underlying mechanism that links this positive feedback loop to breast cancer metastasis, a TAMs-induced EMT cell model (MCF-7) was used. RNA-seq was used to compare the transcriptome of MCF-7 cells which were cocultured with TAMs and those with or without monocyte-derived macrophages (MDMs). Results were further verified by qRT-PCR.

Results: Among 811 known protein-coding genes with reliable readouts, 42 were significantly changed between groups (P<0.001). Further analysis using KEGG, Reactome and Wikipathways databases found that these 42 genes were enriched in 15 signal pathways (P<0.01). According to their biological function, these pathways can be divided into 5 functional groups: SUMOylation related, virus related, immune related, interferon related and cytokine related. The last 3 groups demonstrated that our model were representative and able to provide some real and useful information, while SUMOylation and virus related signal pathways have never been reported to be involved in TAMs induced breast cancer metastasis.

Conclusion: We investigated the transcriptome alteration of MCF-7 cells in the process of TAMs-promoted metastasis. Results from bioinformatic analysis indicated SUMOylation and virus related signal pathways in the process of TAMs induced breast cancer metastasis, which are yet to be confirmed.
Circular RNA NCAPG promotes breast cancer metastasis through acting as the sponge of miR-200s

Yunjie He¹ and Jinhai Tang¹. ¹The First Affiliated Hospital with Nanjing Medical University, Nanjing, China.

Background
Metastatic breast cancer remains incurable and underlying mechanisms are poorly understood. Tumor-associated macrophages (TAMs) represent a major component of the tumor microenvironment that supports breast cancer metastasis. Circular RNAs are new class of endogenous noncoding RNAs. Unlike linear RNAs terminated with 5'caps and 3'tails, they uniquely have a covalently closed loop structure, making them stable and ideal candidate biomarkers. Here, we identified a circular RNA and explored for the first time how it played a dual role in epithelial to mesenchymal transition (EMT) and macrophage recruitment.

Methods
We first analyzed TCGA database about whether mesenchymal tumors could be more likely to recruit TAMs. ELISA assay was performed for determining expression level of chemokines (CSF-1, CCL2, CCL5, C5a, VEGFA, IL-34) after cell line MCF-7 finishing EMT. Next, we predicted microRNAs which could regulate CSF-1 expression and inhibit EMT using Targetscan database. Circular RNA was identified via comparing expression levels between mesenchymal-like and epithelial-like cells using circRNA microarrays. The specific mechanisms were explored via series of molecular biology assays in vitro and in vivo.

Results
Correlation analysis of relationship between EMT score and expression of all classical chemokines that could recruit macrophage revealed a positive association ($r^2>0.3$, $P<0.05$) among 1079 breast cancer cases. Increased expression level of CSF-1 was found the most significant after EMT. miR-200b and miR-200c that inhibiting breast cancer EMT were confirmed targeting 3'UTR of CSF-1 mRNA and decreasing migration of TAMs. Circular RNA NCAPG (circNCAPG) was found highly expressed in mesenchymal-like cells and could promote breast cancer metastasis in vitro and in vivo. Poor clinical outcome was found in circNCAPG overexpression group among 141 breast cancer cases. CircNCAPG was proven to be located in cytoplasm and found could act as the sponge of miR-200b and miR-200c. Moreover, expression level of CSF-1 and ZEB-1 (also targeted by miR-200s and regulating key process of EMT) was found decreasing significantly after knocking down circNCAPG both in vitro and in vivo, leading to breast cancer metastasis inhibition.

Conclusion
Mesenchymal tumors have the ability to recruit more TAMs, therefore further promoting breast cancer metastasis. A new molecule: circNCAPG participates in this process via acting as the sponge of miR-200s and regulates CSF-1 and ZEB-1 expression, which warrants further study in clinical settings.
Conceptual model of transdisciplinary science - Advocacy collaboration for the physical sciences and oncology: A case study focusing on breast density, biomarker discovery, and emerging therapeutics

Susan Samson¹, Jason J Northey², Carole Baas³ and Valerie M Weaver². ¹Breast Science Advocacy Core (BSAC), Breast Oncology Program, Helen Diller Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA; ²Center for Bioengineering and Tissue Regeneration, University of California, San Francisco, San Francisco, CA and ³Physical Sciences-Oncology Network and Office of Advocacy Relations, National Cancer Institute, National Institutes of Health, Rockville, MD.

BACKGROUND: What happens when you mix the foundations of tissue mechanics with advocacy? In a shared quest for exciting scientific frontiers, Bay Area physical scientists, clinical researchers, and advocates work in dynamic symbiotic relationships to integrate concepts drawn from their respective fields. Focusing on the mechanobiology of tumor progression in breast cancer, researchers and advocates are co-creating system change interventions for revamping convergent research processes.

METHODS: As vital catalysts of transdisciplinary innovation, advocates affiliated with the National Cancer Institute (NCI) Physical Sciences and Oncology Network (PS-ON) applied core principles that synergize with the evolving disciplines of Implementation Science (IS) and the Science of Team Science (STS). Diverse methodologies to describe the intersections of physical sciences, breast density, biomarker discovery, emerging therapeutics and advocacy are presented. Additionally, we introduce a theoretical framework and conceptual puzzle illustrating multimethod science advocacy engagement strategies, a typology of contextual factors influencing collaboration, as well as the antecedents, processes, strategic priorities, and overall potential impacts of collaborative transdisciplinary science advocacy exchanges.

RESULTS: Through proactive participation in four areas: 1) research and programmatic support, 2) education and outreach, 3) policy and strategy, and 4) representation and advisory, advocates, representing patient/consumer perspectives, worked toward a common set of goals with researchers and clinicians in determining how tumor microenvironments regulate cancer initiation and behavior through interactions among cell types (e.g., initiated cells, activated stromal cells, and components of the extracellular matrix). Applying NCI Office of Advocacy Relations (OAR) and NCI PS-ON Advocacy Working Group goals for strategic innovation, collaborative execution, and ethical codes of conduct, researchers and advocates co-developed guiding conceptual frameworks based on organizational foundations, systems readiness, leadership commitment to change, and transdisciplinary levers to promote shared governance, bidirectional collaboration, advocacy inclusion, and the prioritization of research addressing questions of importance to patients.

DISCUSSION: Embedding advocate patient/consumer evidentiary and experiential insights/perspectives regarding mechanics-directed research priorities and clinical interventions in the early phase of convergent research efforts contributes to our understanding of the important role of the physical organization in cell-to-cell contacts, tissue architecture, tumor microenvironments, and mechanical properties in response to therapy. Notably, catalyzing and leveraging advocate engagement across the research continuum provides novel opportunities for advancing institutional changes, spurring unique training/mentoring exchanges, and fostering innovative research and translational opportunities.
CCL18 signaling from breast tumor-associated macrophages fosters the activation of fibroblasts into a chemoresistance-inducing phenotype

Erwei Song¹, Shicheng Su¹ and Jianing Chen¹. ¹Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China.

Carcinoma-associated fibroblasts (CAFs) are abundant and heterogeneous stromal cells in tumor microenvironment critically involved in cancer progression. Our recent study identified a specific CAFs subset by two cell-surface molecules, CD10 and GPR77. We proved that CD10⁺GPR77⁺ CAFs could promote tumor formation and chemoresistance by providing a survival niche for cancer stem cells (CSCs). However, their origin and underlying activating initiation mechanism are unclear. Tumor-associated macrophages (TAMs) are the most abundant immune-related stromal cells and the important source of inflammatory cytokine. Here, we demonstrated that CCL18 secreted by TAMs could induces the activation of normal breast fibroblasts into a CD10⁺GPR77⁺ CAFs phenotype, which are not only resistant to chemotherapy themselves, but also can induce chemoresistance in cancer cells by abundantly producing IL-8 and IL-6 and enriching the population of cancer stem cells. In conclusion, our studies have identified an inflammatory signaling network in the interaction of different kind of stroma cells in tumor microenvironment and highlighted its potential values as predictive markers and therapeutic targets to abrogate tumor formation and improve chemotherapeutic efficacy.
Adipose-derived peptides from breast cancer patients promote the malignancy of breast cancer MCF-7 cells

Ziyi Fu1,2,3, Wei Li1, Hao Wu1, Xiang Huang1, Jun Li1, Chunxiao Sun1, Jinhai Tang1 and Yongmei Yin1. 1The First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China; 2Nanjing Maternal and Child Health Medical Institute, The Affiliated Obstetrics and Gybecology Hospital of Nanjing Medical University, Nanjing Maternity and Child Health Care Hospital, Nanjing, Jiangsu, China and 3Northwestern University, Chicago, IL.

Adipose stromal/stem cells (ADSCs) could regulate malignancy behaviors of breast cancer, which was due to adipose-derived cytokines in part, such as leptin and resistin. Recently, peptides have been demonstrated to be potential targets for cancer therapy. It's valuable to analyze the characters of adipose-secreted peptides systematically. In this study, we isolated primary adipocytes from adipose tissue adjacent to breast tumor and breast benign lesions respectively, and then co-cultured breast cancer cells MCF-7 with tumor adjacent adipocytes (TAAs)/breast benign adipocytes (BBAs) separately. Compared to BBAs, TAAs could promote proliferation and migration ability of MCF-7. Then we extracted and purified peptides from supernatant of TAAs and BBAs using ultrafiltration, and the effects of TAAs-derived peptides compound on breast cancer cells appeared accordance with the adipose cells. 100 peptides, which were derived from 90 protein precursors, were found to be differentially secreted between TAAs and BBAs by LC-MS/MS (p < 0.05). Gene Ontology (GO) and Pathway analyses appeared that these altered peptides were mainly contributed to cell adhesion, and regulation of Ras-protein signal transduction. These results showed that these differentially secreted peptides could regulate breast cancer cell malignancy, which indicated that they could be potential therapeutic targets and diagnostic bio-marker for breast cancer.
Role of collagen X in enhancing the metastatic potential of breast cancer cells using a MDA-MB-231 cell line model

Kelsey McKiernan¹, Heather Jimenez¹, Michael McEachern¹, Jacob Hubbard¹ and Malaney O'Connell¹. ¹McMurry University, Abilene, TX.

Breast cancer is the second highest cause of cancer related deaths for women in developed countries. Breast cancer patients with distant metastasis at the time of diagnosis have an estimated 5-year relative survival rate of 26% as compared to a 99% survival rate of patients who have localized tumors. Evidence suggests that collagens play a role in enhancing the metastatic capability of breast cancer cells. Short chain collagen, collagen X, is encoded by the collagen type x alpha 1 chain (COL10A1) gene and is normally expressed exclusively by hypertrophic chondrocytes during endochondral ossification. Recently, COL10A1 gene expression has been found to be overexpressed in various tumor types, including breast tumors. It is hypothesized that an increase in COL10A1 expression may play a role in breast cancer metastasis. The goal of our project was to evaluate the role of collagen X in breast cancer metastasis using the MDA-MB-231 breast cancer cell line. Stable cell lines were generated to express either GFP only (MDA-VEC) or GFP tagged COL10A1 (MDA-COL). GFP and COL10A1 transcript and protein levels were examined to confirm overexpression of collagen X and transwell assays were used to determine changes in the invasive capability of the cells. Cells overexpressing collagen X demonstrated a higher rate of invasion suggesting that collagen X may play a role in enhancing the metastatic potential of breast cancer cells. Understanding the role collagen X plays in breast cancer metastasis may provide a mechanism for developing diagnostic and prognostic strategies for identifying patients whose breast cancer is more prone to metastasize.
DPYSL3 modulates mitosis, migration and epithelial to mesenchymal transition in claudin-low breast cancer

Ryoichi Matsunuma1,2,3, Doug W Chan1, Beom-Jun Kim1, Purba Singh1, Airi Han1,4, Alexander Saltzman1, Chonghui Cheng1, Jonathan T Lei1, Ergun Sahin1, Mei Leng1, Cheng Fan5, Charles M Perou5, Anna Malovannaya1 and Matthew J Ellis1. 1Baylor College of Medicine, Houston, TX; 2Hamamatsu University School of Medicine, Hamamatsu, Japan; 3Hamamatsu Oncology Center, Hamamatsu, Japan; 4Yonsei University Wonju College of Medicine, Wonju, Korea and 5University of North Carolina, Chapel Hill, NC.

Proteogenomics is the field of integrating data from mass spectrometry-based shotgun proteomics, and phosphoproteomics into next-generation RNA and DNA sequencing data analysis pipelines that promises new insights into cancer biology and therapeutic targeting. As well as analyses of clinical samples for disease phenotype association analysis, the application of proteogenomics to model systems also has considerable potential. A Clinical Proteomic Tumor Analysis Consortium (CPTAC) proteogenomic analysis prioritized dihydropyrimidinase-like-3 (DPYSL3) as a multi-level (RNA/Protein/Phosphoprotein) expression outlier specific to the Claudin-Low (CLOW) subset of triple negative breast cancers. A Pubmed informatics tool indicated a paucity of data in the context of breast cancer which further prioritized DPYSL3 for study.

DPYSL3 was identified as a protein that is regulated during neuronal differentiation in the cerebral cortex and in neuronal cell lines and plays a role in regulating neurite outgrowth somehow through an association with vesicles in the growth cone. In addition, DPYSL3 expression has been observed in several malignant tumors, including prostate cancer, pancreatic cancer, gastric cancer and neuroblastoma. DPYSL3 is reported to play a role in cell migration and metastasis suppression in prostate cancer. However, in pancreatic cancer, DPYSL3 is positively associated with liver metastasis and poor outcome.

DPYSL3 knock-down in DPYSL3 (+) CLOW cell lines demonstrated reduced proliferation, yet enhanced motility and increased expression of Epithelial to Mesenchymal Transition (EMT) markers suggesting that DPYSL3 is a multi-functional signaling modulator. Slower proliferation in DPYSL3 (-) CLOW cells was associated with accumulation of multi-nucleated cells indicating a mitotic defect that was associated with a collapse of the vimentin (VIM) microfilament network induced by VIM hyperphosphorylation. On the other hand, DPYSL3 suppressed the expression of EMT regulators TWIST and SNAIL and opposed p21 activated kinase 2 (PAK2) dependent migration, but these EMT regulators in turn induced DPYSL3 expression, suggesting DPYSL3 participates in negative feedback in EMT. Cell migration in DPYSL3 (-) cells correlated with increased phosphorylation of PAK2 on Ser20 and was sensitive to PAK2 siRNA and pharmacological PAK inhibition. Immunoprecipitation and mass spectrometry-based proteomics or western blotting strongly suggests that PAKs interact such that DPYSL3 may function as a direct negative regulator of PAK family kinases. Thus, a PAK inhibitor could potentially mitigate increase migration as an adverse effect of DPYSL3 suppression.

In conclusion, DPYSL3 is a remarkable multifunctional signaling scaffold that should be examined further to provide insights into the stem cell-like state of claudin-low breast cancers, particularly in terms of their cell cycle dependencies, migratory activity and capacity for EMT.
PTK6 small molecule inhibitor enhances efficacies of chemotherapy in mesenchymal TNBC

Koichi Ito 1, EunJee Lee 1, Katsutoshi Sato 1, Jessica H Byerly 1, Jun Zhu 1 and Hanna Y Irie 1. 1Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** EMT in cancer promotes resistance to chemotherapy and radiotherapy, as well as immune suppression in the tumor microenvironment. EMT is also associated with enhanced tumor dissemination to other organs. EMT is a dynamic cell re-programming process whereby cancer cells lose epithelial markers and acquire mesenchymal markers, enhanced cell migration, and anoikis resistance. EMT is promoted by transcriptional and epigenetic regulators, as well as by signaling pathways. TNBCTYPE and 101-gene model have identified distinct subsets of TNBC that exhibit mesenchymal gene signatures and phenotypes. This particular subset may be associated with chemotherapy resistance and metastatic recurrence in patients with TNBC. We identified protein tyrosine kinase 6 (PTK6) as a promoter of EMT in mesenchymal TNBC through its ability to prevent degradation of SNAIL, a key EMT transcriptional factor. A higher level of SNAIL expression is associated with poor TNBC patient prognosis. We investigated whether SNAIL suppression and EMT reversal by PTK6 small molecule inhibitor treatment enhance efficacy of chemotherapeutic agents that are part of standard of care treatment for patients with TNBC. **Methods:** Mesenchymal TNBC cell lines or organoids generated from TNBC PDX tumors were treated with varying concentrations of PTK6 small molecule inhibitor alone or in combination with chemotherapeutic agents in 3D cell cultures. The cell viability was assessed using 3D CellTiter-Glo or alamar blue. The combination Index was calculated to examine potential synergistic effects (CI<1: synergism, CI=1: additive, CI>1: antagonism). The in vivo combination effects of PTK6 inhibitor and paclitaxel were also assessed in two TNBC PDX models. Gene ontology analysis, targeted RT-PCR gene expression profiling and protein array were performed to identify potential mechanisms for chemosensitization effects of PTK6 inhibitor treatment. **Results:** Pre-treatment with PTK6 inhibitor increases sensitivity to paclitaxel or doxorubicin in 3D matrigel culture of TNBC cell lines, as well as in TNBC PDX organoids. The Combination Index suggested synergies between PTK6 inhibitor and chemotherapy treatment (paclitaxel or doxorubicin). While administration of PTK6 inhibitor or paclitaxel alone only modestly suppressed growth of PDX tumors in vivo, PTK6 inhibitor treatment sensitized tumors to paclitaxel treatment, as evidenced by the dramatic suppression of tumor volume and rate of growth. Gene ontology analysis identified gene sets that are significantly differentially expressed in PTK6 inhibitor-treated TNBC tumors, including extracellular matrix, cell migration, cell cycle and microtubule activity. A targeted RT-PCR profiling and protein array found that PTK6 inhibitor modulates expression of molecules that are associated with chemotherapy resistance and immune regulation; decrease in MMP3, PLEK2, osteopontin, IL-6 and CCL5 and increase in CD40. We are currently investigating whether these changes are dependent on Snail downregulation/EMT reversal caused by PTK6 inhibition. **Conclusion:** PTK6 inhibition may sensitize TNBC to chemotherapy treatment by suppressing Snail and reversing EMT. We will further validate these effects of PTK6 inhibitor treatment with other chemotherapies and immunotherapies.
Defining chromatin accessibility profiles of partial and reversible EMT

Kelsey S Johnson¹, Shaimaa Hussein², Yin Lin² and Joseph H Taube¹. ¹Baylor University, Waco, TX and ²Baylor Institute for Immunology Research, Dallas, TX.

The epithelial-to-mesenchymal transition (EMT) reversible cellular reprogramming event, used repeatedly throughout development, is hypothesized to be involved in the cell migration and consequently metastasis that ultimately contributes to most breast cancer-related fatalities. In this process, cuboidal epithelial cells, marked by the presence of tight junction proteins and cell-cell adhesions, lose their apicobasal polarity and acquire a spindle-like morphology and migratory traits. EMT was originally regarded to have only two states, with cells exhibiting either epithelial or mesenchymal phenotypes; however, recently, researchers have demonstrated the existence of a dual epithelial/mesenchymal state, termed hybrid- or partial-EMT. Due to its inherent plasticity, it is believed that EMT and its reversal mesenchymal-to-epithelial transition (MET) is, at least, partly regulated by epigenetic means such as alterations in chromatin structure. Assay for transposase-accessible chromatin with high-throughput sequencing (ATAC-seq) is a novel technique that employs the use of a mutant Tn5 transposase to cleave nucleosome-free DNA regions in a non-biased manner. In this investigation, we induced MCF10A mammary epithelial cells to undergo a short-term (<4 days) or long-term (>4 days) EMT. Addition and withdrawal of exogenous TGFβ1 produced partial- or full-EMT and MET conditions which were interrogated by ATAC- and RNA-seq. Hierarchical clustering of ATAC cleavage peaks revealed that pre-EMT and short- and long-term MET conditions demonstrate similar chromatin accessibility profiles with cleavage sites enriched for specific binding motifs. Notably, transcription factors typically not associated with EMT displayed dynamic enrichment in the accessible chromatin at various timepoints in our assay. Correlation with RNA-seq data reveals highly dynamic changes in gene expression suggesting dynamic and reversible use of regulatory programs. Importantly, partial-EMT cells were characterized by unique accessibility patterns, motif enrichment, and gene expression supporting the conclusion that this is not merely an intermediate but a unique state.
The interplay between stromal density, epithelial mesenchymal transition and chemoresponse in breast cancer

Veenoo Agarwal¹, Lisa Jane Spalding², Tony Blick³, Alexander Dobrovic⁴, Erik W Thompson⁵ and Andrew Redfern¹. ¹Fiona Stanley Hospital, Murdoch, Western Australia, Australia; ²University of Western Australia, Harry Perkins - South, Murdoch, Western Australia, Australia; ³Queensland University of Technology, Kelvin Grove, Queensland, Australia; ⁴Olivia Newton-John Cancer Research Institute, Heidelberg (Melbourne), Victoria, Australia and ⁵Translational Research Institute (TRI), Woolloongabba, Queensland, Australia.

Epithelial Mesenchymal Transition (EMT) refers to the transition of cells from a more differentiated epithelial phenotype to a less differentiated mesenchymal phenotype, a process that may be triggered by a range of therapeutic interventions including cytotoxic treatment, and which we have previously linked to poor breast cancer (BrCa) outcome after neoadjuvant chemotherapy (NAC)¹. Mammographic breast density (MBD) represents the white radiographic appearance of epithelial and stromal breast tissue on a mammogram. High MBD in patients being treated for BrCa also associates with chemoresponse, correlating with lower pathological complete response rates (pCR)². Linking these two stimuli, EMT can also be induced by artificial high-density stroma, where it also leads to chemoresponse in vitro³.

Here we set out to validate the link between poor outcome after NAC and EMT in a larger validatory patient cohort, and to ascertain the molecular drivers through which EMT is triggered in this setting. Further we look to confirm the association of high MBD with poor chemoresponse in the same cohort, and to assess whether this chemoresponse is mediated through EMT with the same drivers.

In a pilot cohort of 50 NAC-treated locally advanced BrCas with a pCR rate of 20%, pre-NAC biopsies and post-NAC surgical specimens were analysed for expression changes in a panel of EMT-related markers across treatment using 230 Nanostring assays. This included the EMT-driving transcription factors TWIST 1 and 2, SNAIL 1, 2 and 3 and ZEB 1 and 2, which were correlated with risk of relapse. Snail-3 showed significantly greater induction in relapers compared to non-relapers (OR=1.8, p=0.04) with a borderline significantly greater induction of TWIST-1 (OR=2.4, p=0.08) in relapers in addition.

In a subsequent 240-patient validation cohort with a pCR rate of 18%, contralateral cranio-caudal view mammograms from the time of diagnosis have been collated and digitized with MBD assessment employing Cumulus software ongoing. Percent breast density will be assessed both as a continuous variable and by quartiles. Immunohistochemistry on pre- and post-operative tissue sections with pan-cytokeratin-vimentin co-staining to identify EMT and staining for SNAIL-3 and TWIST-1 is also in progress. Associations between MBD, EMT before and after chemotherapy, pCR and relapse-free survival will be presented. The role of Snail-3 and TWIST-1 in the interplay between MBD, EMT and outcome is being explored and will be reported.
Differential effects of eribulin on key transcription factors snail and slug

Roma Kaul¹, April L Risinger¹,² and Susan L Mooberry¹,². ¹University of Texas Health Science Center at San Antonio, San Antonio, TX and ²Mays Cancer Center, University of Texas Health Science Center at San Antonio, San Antonio, TX.

Microtubule targeting agents (MTAs) are a mainstay in the treatment of breast cancer and a growing body of evidence demonstrates that they have non-mitotic effects that contribute to their anticancer actions. Even after decades of clinical use, there is much to still be learned about the mechanisms of action these drugs, and differences among them, for optimal utility. MTAs rapidly alter microtubule dynamics, often within minutes, leading to significant changes in oncogenic cellular signaling. We evaluated the early effects of eribulin on key oncogenic signaling pathways following a 2 h incubation using clinically relevant concentrations and compared the effects to those initiated by other MTAs. These studies led to the identification of novel mechanisms by which MTAs disrupt oncogenic signaling and contribute to the reversal of epithelial to mesenchymal transition (EMT), including unanticipated differences among drugs.

The TGF-β-mediated expression of the Snail transcription factor is a key driver pathway of EMT in breast cancer. The effects of eribulin and other MTAs on TGF-β-induced, Smad-dependent expression of Snail were evaluated. Our results show that eribulin and vinorelbine, but not paclitaxel or ixabepilone, inhibit the ability of TGF-β to promote the transcriptional induction of Snail by impeding the nuclear transport of Smad2/3 proteins in 4 triple-negative breast cancer cell lines. This study begins to explain how microtubule disruption might contribute to the eribulin-mediated EMT reversal observed in vitro, in vivo, and in patients.

Slug is another member of the Snail family of transcription factors that plays a central role in breast cancer EMT. Although Snail and Slug are often grouped together due to functional similarities, it is becoming increasingly clear that Slug has an independent role in regulating stemness and cancer cell survival during partial EMT. In contrast to our findings with Snail, eribulin and vinorelbine, but not paclitaxel or ixabepilone, induced Slug expression independent of TGF-β stimulation in a subset of triple-negative breast cancer cell lines. Studies are ongoing to identify the molecular pathways and consequences of eribulin and vinorelbine-induced Slug induction, which might begin to identify biomarkers of patient response to different MTAs. This work highlights the multifaceted nature of MTA-mediated effects on EMT-associated signaling pathways in breast cancer cells and prompts a reevaluation of their differential efficacy in tumors with distinct molecular profiles. These studies are supported by Eisai Inc.
Study of diphenylamine analogs as inducers of mesenchymal to epithelial transition in breast cancer

Akshita B Bhatt, Thomas D Wright, Katie Anna, Mohit Gupta, Suravi Chakrabarty, Patrick T Flaherty, Van Hoang, Matthew Burow and Jane E Cavanaugh. "Duquesne University, Pittsburgh, PA and Tulane University, New Orleans, LA.

The organization of cell cytoskeleton is altered in events of epithelial to mesenchymal transition (EMT), promotion of cell motility, and cancer metastases. EMT is associated with decreased cell-cell adhesion, downregulation of epithelial markers like E-Cadherin, cytokeratins, and occludins, and upregulation of mesenchymal markers such as N-cadherin, vimentin, and various transcription factors such as slug and ZEB. Epithelial to mesenchymal transition is also a consequence of drug resistance and is responsible for cancer metastases. Triple negative breast cancer is highly aggressive cancer and patients show poor prognosis and disease-free survival due to the lack of targeted therapy. Mitogen activated protein kinase pathway, including extracellular activated kinase ERK1/2 and ERK5, and phosphoinositide 3-kinase (PI3K) pathway are known to alter the cytoskeleton through the downstream activation of oncogenes such as FRA-1 and loss of focal adhesions. Of these pathways, the MEK5-ERK5 pathway is understudied in triple negative breast cancer TNBC, and there are few research tools available to selectively inhibit this pathway. The diphenylamine analogs were derived from the parent molecule Mekinist, a FDA approved MEK1/2 inhibitor for melanoma, and modified to gain selectivity towards MEK5. SC-1-151, a type-III allosteric inhibitor of MEK5 is a dual MEK1/2 (98.6%) and MEK5 (59%) inhibitor; the molecule inhibits cell viability and colony formation, and attenuates tumor growth. SC-1-151 was serendipitously identified as a mesenchymal to epithelial transition activator in TNBC cell line MDA-MB-231. E-cadherin protein expression and cell morphology were examined to study MET after the treatment of MDA-MB-231 cells with different structural analogs of SC-1-151 after treatment for 5 days. The compound was further found to induce E-cadherin expression and epithelial phenotype in tamoxifen resistant estrogen positive MCF-7 cell line that underwent EMT. The compound is identified to promote this activity by targeting at least the ERK-FRA1-ZEB1 axis. Alkyl or N-Methyl piperazine substituents on the amide of ring 1 produced similar result as SC-1-151, and substituting the amide group with acid or ester also induced MET. In contrast, ortho-fluoro, para-iodo functional groups of the arene ring 2, when replaced with a meta-bromo substituent did not induce MET. We aim to test the compounds on EGF treated MDA-MB-468 cells to observe the attenuation of EGF induced EMT. Future studies will be performed to determine the specific protein interactions of the promising compounds.
Loss of NSrp70 promotes metastasis of triple-negative breast cancer by activating TGF-β signaling

Yang Zhao¹, Hefen Sun¹ and Wei Jin¹. 'Key Laboratory of Breast Cancer in Shanghai, Collaborative Innovation Center of Cancer Medicine, Fudan University Shanghai Cancer Center, Shanghai, China.

Triple-negative breast cancer (TNBC) is a highly aggressive tumor subtype associated with a poor prognosis. The mechanism involved in TNBC progression remains largely unknown. To date, there are no effective therapeutic targets for this tumor subtype. In this study, by performing quantitative proteomic analyses in highly metastatic and parental breast cancer cell line, we found that nuclear speckle-related protein 70 (NSrp70), a novel serine/arginine (SR)-related protein, was significantly down-regulated in highly metastatic breast cancer cells. Moreover, down-regulation of NSrp70 was also found to promote the migration and invasion of TNBC cells in vitro and in vivo. Mechanistically, loss of NSrp70 increased levels of phosphorylated SMAD3 and TGF-β-induced epithelial-mesenchymal transition (EMT). Furthermore, low NSrp70 expression correlated with poor prognosis in breast cancer patients. Basal-like breast cancer patients with high expression of NSrp70 have better prognosis. However, the expression of NSrp70 have no statistical significance in the Luminal A and luminal B breast cancer patients.

Results
Taken together, our findings reveal that NSrp70 acts as a metastasis suppressor in TNBC by regulating the TGF-β/SMAD signaling pathway and NSrp70 may serve as a novel biomarker of prognosis and the response to anti-tumor therapeutics for patients with TNBC.
Tannic acid inhibited TGFβ-induced phenotype transition and mammosphere formation of breast cancer cells via modulation of NF-κB signaling

Dal-Ah Kim¹²³, Eun-Sun Ryu²³, Hyun-Jung Kang²³ and Duk-Hee Kang¹²³. ¹Innovative Research Center for Control and Prevention of Women's Cancer, Ewha Womans University Mokdong Hospital, Seoul, Republic of Korea; ²Medical Research Institute, School of Medicine, Ewha Womans University, Seoul, Republic of Korea and ³Ewha Womans University School of Medicine, Seoul, Republic of Korea.

BACKGROUND: Cancer stem cells (CSCs) play a crucial role in tumor initiation, metastasis and recurrence, which are therefore regarded as promising therapeutic target. Aberrant NF-κB signaling has been identified in many cancers, and proven to promote CSC formation via several mechanisms, including an induction of epithelial-to-mesenchymal transition (EMT) of cancer cells. Tannic acid (C76H52O46, TA) was reported to inhibit the proliferation of cancer cells, however there was no data regarding the effect of TA on CSCs. The present study investigated the effects of TA on CSC formation, NF-κB signaling, and EMT in breast cancer cells.

MATERIALS AND METHODS: The effect of TA on mammosphere formation and the activity of aldehyde dehydrogenase 1 (ALDH1) was investigated in MCF7 cells. IKK phosphorylation, nuclear translocation of p65 and the expression of IκBα and CSC markers (CD44/CD24, ALDH1) were assessed by western blotting. Role of NF-κB signaling in EMT of MCF7 cells were evaluated using p65 siRNA (sip65) and NF-κB specific inhibitor (PDTC) or IKK inhibitor (Bay11-7082). The effect of TA on tumor growth was also examined in a mouse xenograft model established by subcutaneous implantation of MCF7 cells (1.5 x 10⁷ in 6-week-old Balb/c nude mice with intraperitoneal injection of TGFβ (40 ng/kg, 3 times/week). In 4 weeks of intraperitoneal administration of TA (2 mg/kg, twice/week), tumor volume was measured with an evaluation of the alteration of CSC markers and NF-κB signaling.

RESULTS: TA (10 µM) inhibited the formation and growth of mammosphere in MCF7 cells expressed as a decrease in mammosphere formation efficiency (MFE) and ALDH1 activity. An activation of NF-κB pathway was observed in MCF7-derived mammosphere shown as an up-regulation of p65, a degradation of IκBα and an increased IL-6. Blocking of NF-κB signaling by sip65, PDTC or Bay11-7082 resulted in a decrease in the MFE, the expression of ALDH1, and an increase in CD44⁹⁹/CD24²⁴ ratio. TA alleviated the markers of NF-κB activation in MCF7-derived mammosphere. TGFβ (10 ng/mL)-induced EMT, increase in MFE and NF-κB activation was alleviated by TA. In murine xenograft model, tumor volume was decreased by TA with a decrease in CD44 expression and IKK phosphorylation in xenograft.

CONCLUSIONS: The present study showed that TA inhibited mammosphere formation in breast cancer cells, which was associated with an alleviation of both NF-kB signaling and EMT. Moreover, TA treatment ameliorated tumor growth in an in-vivo mouse xenograft of breast cancer. These data suggest TA may serve as an effective therapeutic agent for breast cancer patients.
Racial/ethnic differences in BRCA1/2 and multigene panel testing among young breast cancer patients

Meghna S Trivedi1, Tarsha Jones2, Xinyi Jiang1, Meghan L Underhill3, Sminu Bose1, Thomas Silverman1, Wendy K Chung1, Rita Kukafka1 and Katherine D Crew1. 1Columbia University Medical Center, New York, NY; 2Florida Atlantic University, Christine E. Lynn College of Nursing, Boca Raton, FL and 3Dana Farber Cancer Institute, Boston, MA.

Background: Breast cancer (BC) patients diagnosed at age 50 and under are recommended to have germline genetic testing for hereditary BC due to a high likelihood of carrying a pathogenic mutation in a moderate or high penetrance risk gene. Completion of genetic testing among racial/ethnic minorities, particularly multigene panel testing, is understudied. We examined predictors of completion of BRCA1/2 and multigene panel testing among women with early onset BC and assessed racial/ethnic differences in genetic testing completion and results.

Methods: We performed a retrospective cohort study of 1370 BC patients diagnosed at ≤50 years of age at Columbia University Medical Center (CUMC) from January 2007-December 2016. Data on socio-demographics, clinical factors, and genetic testing completion and results were collected from the medical record. We conducted descriptive statistics and univariate and multivariable logistic regression models.

Results: Our study population had a median age of 44 years (range, 19-50); 44% non-Hispanic white, 24% Hispanic, 13% non-Hispanic black, 10% Asian, 9% other; 61% private insurance, 22% Medicaid, 17% other. Nearly half of the women (N=607; 44.3%) had genetic testing performed. In the multivariable regression model, genetic testing completion was less likely with increasing age at diagnosis (odds ratio [OR]=0.93; 95% confidence interval [CI]=0.91-0.95) and stage 0 or 4 BC compared to stage 1 (OR=0.67; 95% CI=0.46-0.97 and OR=0.35; 95% CI=0.19-0.64, respectively). Completion of genetic testing was more likely with a family history of BC (OR=5.55; 95% CI=3.92-7.87). Genetic testing completion did not vary by race/ethnicity or insurance coverage. Across all racial/ethnic groups, the frequency of pathogenic/likely pathogenic variants identified was 13.0% and 10.5% had at least 1 variant of uncertain significance (VUS). The highest VUS frequency was among Asians (21.2%). From 2007 to 2016, the percentage of pathogenic/likely pathogenic variants detected increased from 3.4% to 9.1% and the VUS frequency rose from 3.4% to 13.3% with increasing use of panel testing.

Frequency of pathogenic variants and VUS among women ≤50 years diagnosed with BC at CUMC (2007-2016)

| Other variants detected in: APC, BARD1, BRIP1, CDH1, CDKN2A, MEN1, MLH1, MRE11A, MSH2, MSH6, MUTYH, NBN, NF1, PALB2, PHOX2B, PMS2, POLE, PTEN, RAD50, RAD51C, SDHA, STK11, TP53

Conclusions and Relevance: Nearly half of the women with early onset BC had genetic testing. We did not observe disparities in genetic testing by race/ethnicity or insurance coverage. Genetic testing completion, as well as the frequency of pathogenic/likely pathogenic variants and VUS detection, increased over time as panel testing replaced BRCA1/2 testing. Counseling on the likelihood of obtaining uncertain results should be provided to all patients undergoing hereditary BC genetic testing, particularly to racial/ethnic minorities.
Clinical and pathological characteristics and screening outcome for secondary cancers of women with breast cancer and Li-Fraumeni syndrome

Aydah Al-Awadhi¹, Diane D Liu², Angelica M Gutierrez-Barrera², Louise C Strong³ and Banu K Arun²,³. ¹Cancer Medicine Fellowship Program, The University of Texas MD Anderson Cancer Center, Houston, TX; ²The University of Texas MD Anderson Cancer Center, Houston, TX and ³Center for Clinical Cancer Genetics, The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Germline TP53 mutations predispose to early onset breast cancer in women and are associated with Li-Fraumeni syndrome. Published data on the clinical and pathological characteristics and screening outcome for secondary cancers among women with breast cancer and TP53 mutations is limited. To the best of our knowledge this is the largest cohort of breast cancer associated with Li-Fraumeni syndrome.

Methods: Patients with breast cancer and Li-Fraumeni Syndrome were identified from a prospective research database from 2001 to 2017. Patients had genetic counselling and testing at The University of Texas MD Anderson Cancer Center and confirmed to have TP53 mutations associated with Li-Fraumeni syndrome. We reviewed the patient's charts to identify the clinical and pathological characteristics of their breast cancer. Data for secondary cancers are obtained only for patients with breast cancer as their initial cancer diagnosis and who are followed at The MD Anderson's Li-Fraumeni Education and Early Detection (LEAD) clinic which conducts comprehensive cancer screening for these patient's per the NCCN guidelines, including yearly whole body MRIs.

Results: Fifty-nine patients confirmed to have Li-Fraumeni syndrome and breast cancer (100% female, median age 30 years). 94% of the patients were pre-menopausal at the time of breast cancer diagnosis and 6% were post-menopausal due to bilateral salpingo-oophorectomy. 61% were diagnosed after abnormal self or clinical breast exam and 26% based on abnormal screening mammography or ultrasound. In terms of the histologic subtype of breast cancer: 69% had invasive ductal carcinoma, 5% mucinous carcinoma, 5% mixed ductal and lobular, 5% sarcoma, 3% phyllodes tumor and 13% with missing data. Pathologic stage per the 7th edition of AJCC cancer staging system was as follows: 23% stage I, 26% stage II, 23% stage III, 28% remaining with unknown pathologic stage. Pathologic markers include: 70% with positive estrogen receptor expression, 64% with positive progesterone receptor expression, 57% with HER-2 amplification defined per the ASCO-CAP HER-2 test guidelines and 7% with triple negative disease. Forty three patients were followed at LEAD clinic. Of the 43 patients, 40% (N=17) were diagnosed with 1 primary cancer other than breast cancer, 7% (N=7) with 2 primary cancers other than breast cancer and 44% (N=19) with breast cancer only. Out of the 43 patients, 5 were diagnosed with acute myelogenous leukemia, 4 with leiomyosarcoma, 3 osteosarcoma, 4 with other types of sarcoma, 4 with central nervous cell tumors (astrocytoma or glioblastoma multiforme), 3 with papillary thyroid carcinoma, 1 with pancreatic cancer, 1 with renal cell carcinoma, 1 adrenocortical carcinoma, 1 with uterine cancer, 1 with melanoma and 1 with cervical cancer.

Conclusion: This study to our knowledge is the largest cohort of patient's with Li-Fraumeni syndrome and associated breast cancer that is followed in a dedicated clinic for patients with Li Fraumeni Syndrome. This cohort highlights the characteristics of patients with Li-Fraumeni syndrome and associated diagnosis of breast cancer as well as other primary cancers.
Expanded panel testing superior to BRCA1/2 and breast cancer panel in patients with breast cancer

Peter Beitsch1, Pat Whitworth2, Paul Baron3, Barry Rosen4, Gia Compagnoni5, Rache Simmons6, Linda Ann Smith7, Dennis Holmes8, Eric Brown9, Linsey Gold9, Patricia Clark10, Cynara Coomer11, Ian Grady12, Karen Barbosa13, Lee Riley14, Michael Kinney15, Samuel Lyons16, Heather MacDonald17, Sadia Kahn17, Antonio Ruiz18, Rakesh Patel19, Lisa Curcio20, Ed Esplin21, Shan Yang23 and Scott Michalski22, 1TM-E-Dallas, Dallas, TX; 2TM-Nashville, Nashville, TN; 3Roper St. Francis, Charleston, SC; 4Advocate Health, Barrington, IL; 5Advanced Surgical, Barrington, IL; 6Weill Cornell, New York, NY; 7Linda Ann Smith MD, Albaquerue, NM; 8Dennis Holmes MD, Los Angeles, CA; 9Comprehensive Breast Care, Troy, Mi; 10Ironwood Cancer Centers, Phoenix, AZ; 11Staten Island University, Staten Island, NY; 12North Valley Breast Clinic, Redding, CA; 13Alaska Breast Care Specialists, Anchorage, AK; 14St Lukes, Allentown, PA; 15Center for Advanced Breast Care, Arlington Heights, IL; 16Lyons Care Associates, Wailuku, HI; 17Hoag Memorial Hospital, Newport Beach, CA; 18The Breast Center at Chesapeake Regional, Chesapeake, Va; 19Good Samaritan-Los Gatos, Los Gatos, CA; 20Breastlink, Laguna Hills, CA and 21Invitae, San Francisco, CA.

Background: The testing of hereditary breast and ovarian cancer (HBOC) patients for BRCA1/2 only was established years ago to identify patients with clinically actionable variants and limit the economic burden. However, the cost of genetic testing has plummeted, and the number of breast cancer-risk genes with management guidelines has expanded. We created a community-based registry to test all breast cancer patients. A primary objective of this registry included accruing and comparing patients who did and did not meet NCCN guidelines and determining if providing all breast cancer patients with comprehensive multi-gene panel testing yields additional clinical value than testing BRCA1/2 alone.

Methods: An IRB-approved multicenter prospective registry was initiated with 20 community-based and academic breast sites, selected to insure geographic and ethnic diversity. Consecutive patients ages 18-90 with current or prior breast cancer were offered testing with an 80-gene panel (Invitae, San Francisco, CA). HIPAA-compliant case report forms collected patient diagnosis, test results, and physician recommendations made after test results.

Results: Over 1,000 patients were enrolled and data on 911 have been analyzed to date. Median age of patients is 60.5 (range 22 to 93). 56.0% were recently diagnosed with breast cancer. Of these patients, 50.54% met NCCN criteria, and 49.5% did not. 10.9% had history of a prior non-breast cancer. The pathogenic/likely pathogenic (P/LP) variant rate for patients on a comprehensive 80-gene panel was 8.9%. When restricted to a guidelines-based 11-gene breast cancer panel (BRCA1/2, ATM, CDH1, CHEK2, NBN, NF1, PTEN, STK11, TP53, PALB2), 4.9% had P/LP variants; when limited to BRCA1/2, 1.6% had P/LP variants. Of all patients with P/LP findings, 93% had variants in cancer-risk genes with established management recommendations (Table 1) and 80% had germline variants conferring eligibility for precision medicine-based cancer treatments, such as PARP inhibitors, through actively enrolling clinical trials.

Conclusions: This study demonstrates that comprehensive panel testing of breast cancer patients provides a higher yield of clinically actionable P/LP variants than BRCA1/2 testing alone. Limited panels may miss clinically relevant P/LP variants, leaving risk for preventable cancers undiscovered and unnecessarily restricting patients’ treatment options. These results also suggest that variants in tumor suppressor genes, not previously thought related to breast cancer, may contribute to its etiology. A comprehensive panel strategy reveals untapped clinical utility and can impact breast cancer patient care by informing implementation of precision medicine treatment interventions and guiding long-term medical management and surveillance for patients and their family members.

Impact of premenopausal RRSO on breast cancer risk in BRCA1/2 mutation carriers: Maximizing bias-reduction

Neda Stjepanovic, Guillermo Villacampa, Kevin Nead, Sara Torres, Lupe Gomez, Katherine L Nathanson, Alexandre Teule, Joan Brunet, Teresa Ramon y Cajal, Gemma Llort, Rodrigo Dienstmann, Montserrat Rue, Susan Domchek and Judith Balmana. 1Vall d’Hebron University Hospital and Vall d’hebron Institute of Oncology (VHIO), Barcelona, Spain; 2Basser Center for BRCA and Abramson Cancer Center, University of Pennsylvania, Philadelphia; 3Perelman School of Medicine at the University of Pennsylvania, Philadelphia; 4Universitat Politècnica de Catalunya, Barcelona, Spain; 5Catalan Institute of Oncology, IDIBELL, Barcelona, Spain; 6Catalan Institute of Oncology, IDIBGI, Girona, Spain; 7Medical Oncology Service, Hospital Sant Pau, Barcelona, Spain; 8Corporació Sanitària Parc Taulí, Barcelona, Spain and 9University of Lleida-Institute for Research in Biomedicine of Lleida (UdL-IRBLleida), Lleida, Spain.

Background:
To prevent ovarian cancer in BRCA1/2 mutation carriers, risk reducing salpingo-oophorectomy (RRSO) is recommended around age 40. In women with no prior history of cancer, there are conflicting data regarding the impact of RRSO on breast cancer risk. Our aim was to explore the association between premenopausal RRSO and BC risk by using a methodology that maximally reduced potential biases.

Methods:
Prospective multicenter cohort study of BRCA1/2 carriers who underwent genetic testing under age 51, had no history of bilateral salpingo-oophorectomy, mastectomy or cancer prior to genetic testing and during the first six months of surveillance (to avoid cancer-induced testing bias and prevalent cancer bias). Observation period started six months after genetic testing (to avoid event-free time bias), and ended at BC or other cancer diagnosis except for non-melanoma skin cancer and cervical cancer in situ, risk reducing mastectomy (RRM), last follow-up or death. We calculated person-years of observation (PYO) starting at age 30 and RRSO was only accounted for when performed before age 51 (considered premenopausal). Cox proportional hazards models with RRSO as a time-dependent covariate (to avoid immortal person time bias) were used to calculate the BC risk reduction. Sensitivity analysis, censoring at age 51, was performed to calculate the impact of RRSO on the premenopausal BC.

Results:
We included 853 (444 BRCA1 and 409 BRCA2) women. Median age was 36.2 (30-50.9) years, 337 (39.5%) women underwent RRSO prior to age 51 with a median age at RRSO of 42.8 (30.5-50.9) and 240 (28.1%) women performed RRM at a median age of 40.7 (30-61.7) years. After a mean follow-up period of 4.3 years, 96 women (11.3%) were diagnosed with BC (54 BRCA1 and 42 BRCA2). Overall, women who underwent RRSO had a significant reduction in BC risk with hazard ratio (HR) of 0.57 (95% CI= 0.32 to 1; p=0.05); in BRCA1 carriers we found HR of 0.45 (95% CI= 0.22 to 0.92; p=0.03), while BRCA2 carriers had HR of 0.77 (95% CI= 0.35 to 1.67; p=0.51).

When follow-up was censored at age 51, the HR estimates remained similar with overall HR of 0.54 (95% CI= 0.29 to 1; p=0.05); BRCA1 carriers had HR of 0.35 (95% CI= 0.15 to 0.82; p=0.02), while BRCA2 carriers had HR of 0.88 (95% CI= 0.39 to 1.96; p=0.75).

Conclusions:
This robust bias-reducing analysis in a large prospective cohort supports a role of premenopausal RRSO for BC risk reduction in BRCA1 carriers. A longer follow-up may be needed to estimate the potential benefit of the intervention in BRCA2 carriers.
HEREDITARY BREAST CANCER BEYOND BRCA: CLINICAL AND HISTOPATHOLOGICAL CHARACTERISTICS IN PATIENTS WITH GERMLINE CHEK2, ATM, PALB2 AND TP53-MUTATIONS

1 University Hospitals Leuven, Leuven, Belgium.

Background

The introduction of multi-gene panel testing in the diagnosis of hereditary breast and ovarian cancer (HBOC) has led to an important increase in the detection of breast cancer predisposition genes other than BRCA1 and BRCA2.

Methods

All individuals who underwent HBOC-testing at our institution since the introduction of multi-gene panel testing were included (March 2016-August 2017). In this retrospective analysis, the BRCA Hereditary Cancer MASTR Plus® panel is used (Multiplicom, Belgium), with sequencing of BARD1, BRCA1, BRCA2, BRIP1, RAD51C, RAD51D, TP53, MRE11A, RAD50, NBN, FAM175A, ATM, PALB2, STK11, MEN1, PTEN, CDH1, MUTYH, CHEK2, BLM, XRCC2, EPCAM, MLH1, MSH6, PMS2, MSH2.

In breast cancer patients with a recurrent germline alteration, age and TNM stage at diagnosis, histological subtype, grade of differentiation and molecular surrogate subtype were recorded. Given the low numbers of TP53-carriers diagnosed by HBOC testing, also patients with a germline TP53-mutation diagnosed by targeted sequencing at our institution were included. Statistical analysis were performed with SPSS version 25.

Results

In 11.9 % of 2806 patients who underwent panel testing, a germline pathogenic alteration was detected. BRCA1 and BRCA2 were the most prevalent alterations, detected in respectively 3.35 and 2.92 % of patients. Germline alterations in CHEK2, ATM, PALB2 and TP53 were detected in respectively 2.5 %, 1.1 %, 0.5 % and 0.1 %. In 1 % of patients, germline alterations were retrieved that only contribute to ovarian cancer risk (BRIP, RAD51C, RAD51D). Germline DNA mismatch repair alterations were detected in 0.39 % of patients.

The median age at onset of breast cancer in patients with germline CHEK2-, ATM-, PALB2- and TP53-mutations was 47, 53, 39 and 33 years respectively. The age of breast cancer diagnosis in patients with germline TP53-alterations was significantly younger compared to patients with CHEK2-mutations (p = 0.01), ATM-mutations (p = 0.01) and PALB2-mutations (p = 0.04). In situ carcinomas were diagnosed in respectively 9 %, 11 % and 11 % of patients with CHEK2-, PALB2- and TP53-mutations. Patients with CHEK2, ATM, PALB2 and TP53-alterations were diagnosed with ≥T3-tumors in respectively 13 %, 12 %, 33 % and 22 %. Nodal status at diagnosis was negative in 40-60 % in these 4 subgroups. Upfront metastatic disease was diagnosed only in 2/43 CHEK2-carriers. More than half of the breast cancer diagnoses were luminal tumors in CHEK2-, ATM- and PALB2-carriers, while cases with germline TP53-alterations only presented with luminal cancers in 22 % in our series.

Conclusion

Almost half of the pathogenic mutations detected in HBOC-genes are alterations in genes other than BRCA1 and BRCA2. CHEK2-mutations are by far the most prevalent, followed by ATM, PALB2 and TP53.

The range of the CHEK2- and ATM-population was wider then expected at the lower-age boundary. The age of breast cancer diagnosis in patients with germline TP53-mutations was significantly younger compared to patients with CHEK2-, ATM- and PALB2-mutations. The distribution of the histological subtypes and grade of differentiation was not suggestive of a specific correlation with germline mutation status.
Underdiagnosis of HBOC in breast cancer patients: Are genetic testing guidelines a tool or an obstacle?

Peter Beitsch1, Pat Whitworth2, Paul Baron3, Barry Rosen4, Gia Compagnoni5, Rache Simmons6, Linda Ann Smith7, Dennis Holmes8, Eric Brown9, Linsey Gold9, Patricia Clark10, Cynara Coomer11, Ian Grady12, Karen Barbosa13, Lee Riley14, Michael Kinney15, Samuel Lyons16, Heather MacDonald17, Sadia Kahn17, Antonio Ruiz18, Rakesh Patel19, Lisa Curcio20, Ed Esplin21 and Shan Yang21. 1TME Dallas, Dallas, TX; 2TME Nashville, Nashville, TN; 3Roper St. Francis, Charleston, SC; 4Advocate Health, Barrington, IL; 5Advanced Surgical Care, Barrington, IL; 6Weill Cornell, New York, NY; 7Linda Ann Smith MD, Albuquerque, NM; 8Dennis Holmes MD, Los Angeles, CA; 9Comprehensive Breast Care, Troy, MI; 10Ironwood Cancer Centers, Phoenix, AZ; 11Staten Island University, Staten Island, NY; 12North Valley Breast Clinic, Redding, CA; 13Alaska Breast Care Specialists, Anchorage, AK; 14St. Lukes, Allentown, PA; 15Center for Advanced Breast Care, Arlington Heights, IL; 16Lyons Care Associates, Wailuku, HI; 17Hoag Memorial Hospital, Newport Beach, CA; 18The Breast Center at Chesapeake Regional, Chesapeake, VA; 19Good Samaritan, Los Gatos, CA; 20Breast Link, Laguna Hills, CA and 21Invitae, San Francisco, CA.

Background: Pathogenic genetic variants are estimated to occur in 10-15% of all breast cancer patients, with BRCA 1/2 accounting for 40-50% of pathogenic/likely pathogenic (P/LP) variants. However, it is estimated that <30% of breast cancer patients harboring a BRCA 1/2 variant have been identified, with the percentage being much less for ~20 other breast cancer associated genes. Reasons for this are multifactorial and include complicated and restrictive testing guidelines developed at a time when the cost of testing was high and guidelines for management were limited. Today, cost has plummeted and there are definitive management guidelines for a broader range of genes. We created a community based Registry to determine the incidence of P/LP variants in breast cancer patients who meet and who do not meet the NCCN 2017 genetic testing criteria.

Methods: An IRB-approved multicenter prospective registry was initiated with 20 community and academic sites experienced in cancer genetic testing and counseling. Eligibility criteria included patients with a breast cancer diagnosis who had not been previously tested. Consecutive patients aged 18-90 were consented and underwent an 80 gene panel test (Invitae –Multi-Cancer Panel). The non-inferiority study was powered to detect a difference in P/LP variant rate of 4 percentage points with statistical significance (p<0.05, Fisher’s exact test). HIPAA compliant electronic case report forms collected information on patient diagnosis, test results, and physician recommendations made after test results were received.

Results: Over 1000 patients were enrolled and data from 910 subjects analyzed to date. 50.4% met NCCN criteria and 49.5% did not. Median age for the enrolled patients is 60.5 and ranged from 22-93. 56.0% of patients were recently diagnosed with breast cancer. 10.9% of patients had a history of a prior non breast cancer. Overall, 8.9% of patients had a pathogenic variant. 9.6% of patients who met NCCN criteria with test results had a P/LP variant. 8.2% of patients who did not meet criteria had a P/LP variant. The difference of positive cases among the two groups is not statistically significant (P = 0.49)

4.9% of patients had pathogenic variants if only an 11 gene standard breast cancer panel was considered. The spectrum of mutated genes varied between the two groups, with some overlap.

Conclusions: There was no statistically significant difference in the number of pathogenic/likely pathogenic variants between those patients who met and those who did not meet NCCN guidelines. Expanded panel testing yields more medically actionable P/LP variants than testing BRCA 1/2 alone or breast cancer panels with 11 genes. This study demonstrates that there will be a significant number of patients with P/LP variants are missed if NCCN guidelines are required for genetic testing. Current NCCN guidelines for the genetic testing of breast cancer patients are an obstacle to identifying patients with P/LP variants and should be removed.

Risk reducing strategy in germline BRCA mutated patients with locally advanced breast cancer. Establishing mastectomy as a preventing procedure of local recurrence

Christine Tunon de Lara1, Jeanne Leroux2, Françoise Bonnet1, Marc Debled1, Emmanuelle Barrouk-Simonet1, Nathalie Quenel-Tueux1, Philippe Lagarde1, Florence Chassaigne1, Thomas Esnault2, Marion Fournier1, Virginie Bubien1, Christèle Breton-Callu1, Hélène Charitansky1, Adeline Petit1, Simone Mathoulin-Pelissier1, Gaétan Macgrogan1, Michel Longy1 and Nicolas Sevenet2. 1Institut Bergonié, Bordeaux, France and 2Université de Bordeaux, Bordeaux, France.

Introduction
Neoadjuvant chemotherapy (NAC) is proposed for locally advanced breast cancer (LABC) to increase the breast conservative treatment (BCT). In France, mastectomy is the risk-reducing prophylactic surgical strategy only for pre-symptomatic germline BRCA-mutated (gBRCAm) patients. On the other hand, BCT is proposed to all patients following NAC based on clinical response, regardless the gBRCAm status. The aim of this retrospective study is to evaluate the risk of local recurrence (LR) according to BRCA status.

Patients and methods
Inclusion criteria were: (i) patients treated for unilateral LABC, T2-3, N\(\geq\)0, M0 by NAC, and (ii) patients who underwent germline BRCA screening. , using targeted next-generation screening, was carried out either during NAC (rapid process) or after surgery. Deleterious mutations were confirmed using Sanger sequencing before passing on the results to the clinical geneticist. Some gBRCAm patients from Olympia study were also included. Patients were followed-up over a long term for overall survival, LR and disease-free survival. Chi-square and Fischer test were used to generate statistical comparison.

Results
Between 2007 and 2015, 988 women were treated for LABC at our institution. Among them, 151 patients underwent clinical genetic testing for gBRCAm based on these criteria: young age at diagnosis or familial history of breast or ovarian cancer or histological characteristics as grade 2/3, Her2-3+ or basal like. A total of 122 patients were included in the study; 28 patients had gBRCAm status and no mutations were detected in 94 patients (wtBRCA). Significant differences between the two groups (gBRCAm vs wtBRCA) were observed for
Mean age, (36.7 vs 40.1y (p=0.0032) ,
Intrinsic tumor subtypes basal like (64.3% vs 42.5%, p=0.0432)
ER are more often negative (21.4% vs 46.8%, p=0.0165).
Among the 30 patients who underwent BRCA screening during NAC and eligible for BCT, 8 of the 9 patients with gBRCAm choose mastectomy (88%). Among the 92 patients with screening mutation after breast cancer treatment, 5 of the 19 patients with gBRCAm had a mastectomy (28%). In the 28 gBRCAm patients, 15 had a BCT and 13 a mastectomy. In the 94 wtBRCA patients, 67 had a BCT and 27 a mastectomy. After a follow-up of 4.32 years, we observed 8 relapses, 5 LRs after BCT and 3 contro-lateral relapses. Of the 5 LRs, 3 came from 15 gBRCAm with BCT and 2 of the 67 wtBRCA (p=0.0403).

Discussion
In this selected subgroup of patients, gBRCAm rate is higher (23%) than the rate based on familial criteria for BRCA testing (12%). Regarding the rationale for BCT or mastectomy procedure in LABC and pre-symptomatic gBRCAm patients, this study led us to establish mastectomy as risk-reducing strategy in a sole surgery procedure for gBRCAm patients. Moreover, 88% gBRCAm patients chose mastectomy; the mastectomy rate was lower when the patient was unaware of their BRCA status (26%). The LR rate was higher in the gBRCAm vs wtBRCA with a statistical difference. In LABC patients with high genetic risk, the knowledge of mutation status could influence patients’ and surgeons’ choice of surgery. In case of gBRCAm status, mastectomy is recommended to decrease LR risk.
Germline variants in non-BRCA homologous recombination genes detected in HER2-negative breast cancer patients

Kristen J Vogel Postula¹, Anna K McGill¹, Erin Sutcliffe¹, Patricia D Murphy¹, Rachel T Klein¹ and Kathleen S Hruska¹. ¹GeneDx, Gaithersburg, MD.

Background: PARP inhibitors (PARPi) are FDA approved for a subset of metastatic human epidermal growth factor receptor 2-negative (H2N) breast cancer patients who harbor a germline pathogenic or likely pathogenic variant (PV) in BRCA1/2, two of the most well-described breast cancer susceptibility genes in the homologous recombination (HR) pathway. While the NCCN guidelines recommend consideration of BRCA1/2 testing for patients with H2N disease that are eligible for single-agent therapy, there are currently clinical trials available for women with advanced H2N breast cancer who have PVs in HR genes beyond BRCA1/2 to investigate outcomes of receiving PARPi. The yield of germline PVs in other HR genes in the H2N population is not well-described.

Methods: Clinical histories and test results were reviewed for women with a diagnosis of H2N breast cancer who underwent multi-gene hereditary cancer panel testing that included a minimum of 10 homologous recombination (HR) genes in addition to BRCA1/2 (ATM, BARD1, BRIP1, CHEK2, FANCC, NBN, PALB2, PTEN, RAD51C, RAD51D). Those with prior BRCA1/2 testing were excluded. We assessed the yield of PVs in non-BRCA1/2 HR genes in the H2N breast cancer population. In addition, we compared the yield of PVs in non-BRCA1/2 HR genes in a “low risk” population (probands with H2N breast cancer with no reported personal history of ovarian or pancreatic cancer and no reported family history of breast, ovarian, pancreatic, or prostate cancer) to a “high risk” population (probands with H2N breast cancer who also have a personal history of ovarian or pancreatic cancer and/or a reported family history of breast, ovarian, pancreatic, or prostate cancer) via a two-tailed Fisher's exact test.

Results: A total of 6179 women with H2N breast cancer were identified. Of these, BRCA1/2 PVs were identified in 4.8% (299/6179), while 5.7% (351/6179) carried PVs in HR genes other than BRCA1/2. These included CHEK2 (145), ATM (62), PALB2 (59), BRIP1 (26), FANCC (18), BARD1 (17), RAD51C (12), NBN (11), RAD51D (6), and PTEN (2). No statistically significant difference in the likelihood to harbor a PV in one of the 10 non-BRCA1/2 HR genes was observed between those with a “low risk” presentation (4.8% (53/1096) as compared to those with a “high risk” presentation (5.9% (298/5083)) (p=0.1956).

Conclusions: Our findings show that the yield of PVs in HR genes other than BRCA1/2 is appreciable in the H2N breast cancer population. As such, it may be beneficial to include all HR genes when testing H2N breast cancer patients, regardless of other personal or family history, if and/or when a patient develops metastatic disease.
CHEK2: the third susceptibility BREast CANcer (BC) gene?

Vera L Gomes¹, Patrícia Machado³, Sofia Fragoso³, Sidonia Santos³, Irina Coelho², Joana Parreira⁴, Paula Rodrigues², Fátima Rodrigues², Ana Clara¹, Sandra Bento², Ana Luis¹, Ana Opinião¹ and Fátima Vaz¹. ¹Portuguese Oncology Institute Francisco Gentil of Lisbon/ Departamento de Oncologia Médica, Lisbon, Portugal; ²Portuguese Oncology Institute Francisco Gentil of Lisbon/ Clínica de Risco Familiar (CRF), Lisbon, Portugal and ³Portuguese Oncology Institute Francisco Gentil of Lisbon/ Unidade de Investigação em Patobiologia Molecular (UIPM), Lisbon, Portugal.

INTRODUCTION:
Considered a medium penetrance gene, CHEK2 codes for a kinase that is a key component of the DNA damage-signaling pathway. CHEK2 pathogenic variants were previously associated with breast and colorectal families and also with Li-Fraumeni phenotypes. Next generation sequencing (NGS) allowed for systematic inclusion of CHEK2 into gene panels. In here, we characterize the growing subgroup of CHECK2 BC families identified through our multidisciplinary program.

METHODS:
Identification and review of CHEK2 families identified between 01/2000-06/2018 (until 2014 only the c.1100delC was tested (MLPA, MRC Holland); since 2014 NGS methods used were either Trusight Cancer sequencing panel (Illumina, San Diego, CA, USA) or BRCA MASTR Dx (Multiplicom, Niel, Belgium). Carriers were included in a prospective follow up program.

RESULTS:
3646 index pts consented on gene testing. Most hereditary families (HF) were BRCA1/2 (374) (92%) but among non-BRCA HF bigger subgroups were 16 CHEK2, 10 Tp53 and 5 PALB2 HF. All CHEK2 index pts were diagnosed with only 3 different pathogenic variants: c.1100delC (9) c.319+2T>A (6) and c.593-1G>T (1 case of the only male BC pt in all CHEK2 pedigrees).

Index pts: mostly (93,8%) to females, with a mean age at first cancer diagnosis of 39 years (yrs) (30-52), 62,5% between 30-39yrs. With the exception of a Non Hodgking's Lymphoma index case, all index pts had BC(93,8%), 68,8% of which were ductal carcinomas and 12,5% of intraductal, all strongly positive for the estrogen receptor. With a mean follow up of 8,26yrs (3-15), secondary cancer cases occurred in 37,5% of index pts (mostly, 12,5%, BC at a mean of 53yrs (41-59).

Family phenotypes: data form 98 relatives (53,5% females) revealed diagnoses of BC (31,6%), prostate (8,1%), colorectal (7,1%) cancers. Only 22,2% of family cancers were diagnosed before 50yrs.

VUS: Among several complex variants of unknown significance, c.1036C>T;p.Arg346Cys co-segregates in a predominantly male family with 3 prostate, 1 male and 1 female BC.

DISCUSSION AND CONCLUSIONS:
In the Portuguese population, emerging recurrent pathogenic variants in the CHEK2 gene, make it the most important non-BRCA BC gene so far. Carriers are included in prospective follow up but non-CHEK2 relatives are a challenge to genetic testing, as well as pedigree review, that questions its classification as a medium penetrance gene (or suggest the role of modifier factors).
Uptake of genetic testing and prevalence of mutations among minority populations: A retrospective cohort study

Prathima Nagireddy¹ and Pamela Ganschow². ¹Cook County Health and Hospital System, Chicago, IL.

**Background:** Hereditary cancer syndromes account for 5-10% of cancers. Limited data exists on the uptake of genetic testing and the prevalence of mutations in minority populations.

**Objective:** To estimate genetic testing uptake and prevalence of mutations in a minority population seeking care in a safety net healthcare system.

**Methods:** We conducted a retrospective cohort study of patients who were assessed at John H Stroger Jr., Hospital of Cook County cancer genetics risk clinic between October 2015 and March 2018 to determine the uptake of genetic testing and the prevalence of genetic mutations. Patients who met National Comprehensive Cancer Network (NCCN) guidelines for genetic testing for hereditary breast and ovarian cancer syndrome (HBOC), Lynch syndrome and familial adenomatous polyposis were included. Data was abstracted through chart review to obtain age, socio-demographics, personal cancer history, primary language, personal and family history of cancer including type of cancer and age at diagnosis, insurance status, genetic testing status and test results. Uptake of testing was calculated as the percentage of patients who underwent testing among those patients who met NCCN criteria for testing. Prevalence of mutations among those patients who underwent testing was determined and compared between different ethnicities using Chi-square test.

**Results:** Of 510 patients offered genetic counseling & testing, 478 (94%) underwent genetic testing. Among those who tested, 34% (n=165) were African American and 45% (n=212) were of Hispanic origin. Prevalence of any mutation was 48%(n=232), Pathogenic mutations were identified in 11% (n=54) of testers and variants of uncertain significance (VUS) were identified in 37% (n=132) respectively. Deleterious mutations and VUS rates in patients affected with hereditary cancer syndromes were 13% (n=42) and 39 % (n=132) respectively. Deleterious mutations and VUS rates in women unaffected with cancer were 9% (n=12) and 33 % (n=46) respectively. Overall mutation prevalence did not differ between affected and unaffected patients (p=0.12) or between Black and Hispanic patients (p=0.96). Deleterious mutation rate in Hispanic patients was 15.6% (CI 20.5%-10.7%) and in Black patients was 3.6% (CI 3%-4%). There was a significant difference in the percentage of deleterious mutations between Hispanic and Black patients (p=0.0009).

**Conclusion:** Genetic testing uptake was high in minority populations. In the Population who were tested prevalence of pathogenic mutations was higher among Hispanics than African Americans.
Direct-to-consumer genetic testing as an alternative model for identifying BRCA carriers

Ruth Tennen¹, Sarah Laskey¹, Bertram Koelsch¹, Matthew McIntyre¹, Anne Greb¹, Esther Kim¹ and Joyce Tung¹. ²3andMe, Inc., Mountain View, CA.

**Background:** Three BRCA1 and BRCA2 founder variants (185delAG, 5382insC, and 6174delT) are common in the Ashkenazi Jewish population. Our objective was to use data collected by direct-to-consumer (DTC) genetic testing (23andMe, Inc., Mountain View CA) to determine the frequency of these variants in a generally unselected group of genotyped individuals and to characterize the cohort of individuals carrying one of these variants in terms of self-reported ancestry, genetic ancestry, and personal and family history of cancer.

**Methods:** Individuals were genotyped prior to November 2017 on one of four custom Illumina genotyping arrays, which included the three Ashkenazi founder variants. Ashkenazi Jewish genetic ancestry was calculated by an analysis of local ancestry. Self-reported data from customer surveys on ancestry and personal and family history of cancer was used in the analysis. Inclusion criteria were 23andMe customers who were 18 years or older and consented to participate in research. IRB approval was obtained from Ethical & Independent Review Services.

**Results:** More than 80% of individuals consented to participate in online research. 2,853 carriers of at least one Ashkenazi Jewish founder variant were identified out of 1,980,076 eligible participants. 54% (1,539) were males; 46% (1,314) were females; 86% (2,462) were over 30 years of age. 249 (9%) had no detectable Ashkenazi Jewish genetic ancestry. 1,967/2,853 (69%) provided self-reported ancestry information. 415/1,967 (21%) did not self-report Jewish ancestry but of those, 258 (62%) had at least 1% Ashkenazi Jewish genetic ancestry. Individuals with less than 20% Ashkenazi Jewish genetic ancestry were less than 50% likely to report having Jewish ancestry.

1,837 participants provided personal cancer history information and 393 provided first-degree family history information. 1,435/1,837 (78%) reported no personal history of breast, ovarian, pancreatic, or prostate cancer. 44% (172/393) reported no first-degree family history of breast, ovarian, pancreatic, or prostate cancer.

**Conclusions:** This is the first description of a large, unselected cohort of BRCA carriers identified through DTC genetic testing. 21% of carriers in our cohort did not self-report Jewish ancestry despite more than half of those having detectable Ashkenazi Jewish genetic ancestry. Even though personal or family history was only available for a subset, many did not report suggestive histories of breast, ovarian, prostate, or pancreatic cancer. Although there are limitations to the data set, these findings suggest the need for alternative models for identifying carriers of specified BRCA variants who may not otherwise be identified for genetic testing. Additionally, the number of males identified underscores the importance of male carriers in cancer genetic risk assessment.
Germline mutation in TP53 gene in a cohort of 2,561 Chinese high-risk breast cancer patients using multigene panel testing

Ava Kwong¹²³, Vivian Shin¹, Chun H Au³, Cecilia Ho³, Thoams Slavin⁴, Jeffrey Weitzel⁴, Tsun L Chan²³ and Edmond Ma²³. ¹The University of Hong Kong, Pokfulam, Hong Kong; ²Hong Kong Hereditary Breast Cancer Family Registry, Shau Kei Wan, Hong Kong; ³Hong Kong Sanatorium & Hospital, Happy Valley, Hong Kong and ⁴City of Hope, Duarte, CA.

Background: Li-Fraumeni syndrome (LFS) is a rare autosomal genetic disorder with germline TP53 mutations. Patients with TP53 mutations have a higher risk of developing breast cancer than those harboring BRCA mutations. Although limited studies have shown that TP53 mutation carriers are less responsive to low dose radiation and more susceptible to induce new malignancies from radiotherapy. Moreover screening strategies allows early detection of a spectrum of cancers related to TP53 mutations. From work of BRCA mutations where over 40% novel mutations were detected in Chinese cohort, it is important to evaluate the frequency of TP53 mutation in Chinese to better understand the spectrum to guide appropriate clinical management of these high risk individuals.

Methods: TP53 gene mutation screening was performed on 2,561 high-risk breast cancer patients using multigene panel testing. The patients were accrued by Hong Kong Hereditary and High Risk Breast Cancer Program from March 2007 to May 2018. All detected pathogenic mutations were further validated by bi-directional DNA sequencing and analyzed by our in-house developed bioinformatics pipeline.

Results: Sixteen distinct pathogenic or likely pathogenic variants were identified, and 3 of them were de novo TP53 mutations (18.75%). The mean age of patients who harbored TP53 mutation was 30.44 years (range 18-44), and 50% of the tumors were bilateral breast cancer. Of sixteen different pathogenic mutations, majority of them were missense mutation (87.5%), and 2 were nonsense mutation (12.5%). Four of the sixteen TP53 mutation carriers had family history of breast cancer, while others had a family history of lung cancer (43.75%).

Conclusion: This study revealed that seven patients were found to harbor TP53 mutation even when they did not meet the criteria of LFS of LFS-like phenotype, implicated the importance of using multigene panel test for probands and their relatives to offer a comprehensive surveillance programe for TP53 carriers.
Disparities in germline mutation testing: do Medi-Cal and uninsured patients with breast cancer receive genetic testing in a safety net setting?

Kathy Pan¹, Jessica E Yan¹, Karen T Huynh¹, Kevin A Peng², Junko Ozao-Choy¹, Christine Dauphine¹, Susan Park¹ and Patricia I Dickson¹. ¹Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA and ²House Clinic, Los Angeles, CA.

Background: National Comprehensive Cancer Network guidelines recommend that women with breast cancer diagnosed at age ≤50 undergo cancer genetic risk assessment and that those age ≤45 undergo testing for hereditary breast and ovarian cancer (HBOC) syndromes such as BRCA. In prior studies of primarily commercially insured women, 30% of those ≤40 years of age received BRCA testing (Levy 2011), and 34% of those ≤50 years were referred for genetic assessment (Stuckey 2016). Our aim was to determine rates and predictors of genetic testing among publicly insured or uninsured women at a safety net medical center.

Methods: Women diagnosed with invasive breast cancer or ductal carcinoma in situ from 2010 through 2016 were identified from the institutional tumor registry of a Los Angeles County public hospital. Eligible for this analysis were those at high risk for HBOC syndromes as defined by 1) age ≤50 at diagnosis or 2) age ≤60 with triple negative breast cancer. Women were excluded if they received all of their cancer treatment at an outside institution. Medical records were reviewed to determine receipt of genetic testing and test results. Univariate logistic regression was used to evaluate associations between patient characteristics and receipt of testing.

Results: 307 women were included in the analysis. 92.5% (284) were age ≤50 and 54.7% (168) were age ≤45. The majority (72.1%) had Medi-Cal or Medicare and 26.1% were uninsured at diagnosis. The racial distribution was 63.8% Hispanic, 19.2% black, 11.1% Asian and 5.5% non-Hispanic white. Overall, 52.1% (160/307) underwent genetic testing and 13.1% (21/160) were found deleterious germline mutations (BRCA1=10, BRCA2=8, BRCA not specified=1, PALB2=1, TP53=1). Among women who underwent testing, 55.0% were tested for BRCA1/2 only and 36.8% received multigene panel testing; specific testing information was unavailable for the remainder. Age, race/ethnicity, and presence of metastatic disease at diagnosis were associated with differences in genetic testing rates, whereas insurance status and year of cancer diagnosis were not (Table 1).

Conclusions: In a safety net setting with mostly Medi-Cal-insured and uninsured patients, the overall rate of germline mutation testing in women with breast cancer (52.1%) was at least comparable to that in studies of commercially insured populations. Notably, testing rates in this population were significantly different when stratifying by age, race, and cancer stage. These findings highlight subgroups in this underserved population who warrant additional attention to assessment of their cancer genetic risk.

*1 patient had Medicare; the remainder had Medi-Cal
Prevalence and type of BRCA mutations in young breast cancer patients undergoing genetic cancer risk assessment in two developing countries: Analysis of two cohorts from Romania and Mexico

Saul Campos-Gomez, Nicoleta Antone, Guillermo Pacheco-Cuéllar, Laura Pop, Karen Campos Gomez, Andrei Stoian, Rares Eniu, Juan Valdes-Andrade, Eleonora Dronca, Ramona Matei, Marjolijn Ligtenberg, Hicham Ouchene, Andrea Onisim, Olivia Rotaru and Alexandru E Eniu. 1Centro Oncologico Estatal ISSEMyM, Toluca, Mexico; 2Ion Chiricuta Oncology Institute Cluj-Napoca, Romania, Romania; 3Research Center for Functional Genomics (RCFG), Biomedicine and Translational Medicine, Iuliu Hatieganu University of Medicine and Pharmacy, Romania, Romania; 4Cardiff University School of Medicine, Cardiff, United Kingdom and 5Radboud University Medical Center, Nijmegen, Netherlands.

Background: a previous study found significant clinicopathological differences between young Breast Cancer BrCA patients (pts) from Romania (Ro) and from Mexico (Mx). Here, we provide a molecular and clinical description of pts carrying BRCA mutations of both cohorts.

Methods: in this retrospective study, we analyzed 2 cohorts of BRCA1/2 mutations carriers tested in COEI from Mx between 2014-2017 and IOCN from Ro between 2015 to 2016. Ro pts were selected according to NCCN criteria, while Mx pts were selected based on risk evaluation models. NGS analysis and MLPA for BRCA1&2 were performed in all pts. We compared demographic, clinicopathological and molecular data.

Results: 65 pts, 21 (32.7%) from Mx and 44(67.7%) from Ro carried a BRCA mutation. 66.7% of Mx pts and 65.9% of Ro pts carried a BRCA1 mutation. We found clinical similarities: Mean age was 44.5y for Mx and 40.59y for Ro pts. IDC was the most frequent type of BrCa in both series (90.5 vs 90.9%). TNBC was seen in 13 Mx vs 27 Ro pts (61.9% vs 61.4%), HR positive was seen in 7 (33.3%) and 12 (27.3%) cases. Grading 3 was more frequently seen in Ro, while grading 2 was mainly noted in MX pts(p=<0.020). BRCA1/2 pathogenic mutations were different between the 2 cohorts and no BRCA 1/2 identical mutation was identified. 15 different mutations in 21 Mx pts, and 16 different mutations in 44 Ro pts were found. Mutations were different between 2 cohorts. Notably for the Ro cohort, 4 founder mutations (c.181T>G, c.3607C>T, c.5266dupC in BRCA1, and c.9928A>G[GPC1] in BRCA2) were found in 31/44 pts, while the Mx cohort, c.5123C>A and del 9-12del ex in BRCA1 were found in 6/21 mutations. Three Large rearrangements (LR) were exclusively seen in the Mx pts (5/21).

Conclusions Both cohorts didn't share any mutation, but the clinical features are similar. BRCA1 del 9-12del is a Mexican founder mutation, we found it in 14% of Mx pts, LR have been described more frequently in Latin American Populations, we found it in 30% of the MX cohort, while for Ro cohort four recurrent mutations qualify as founder mutations.
Is BRCA-testing based on risk models still a valid approach in developing countries?

Guillermo Pacheco-Cuellar1, Juan Valdes-Andrade1, Karen A Campos-Gomez1 and Saul Campos-Gomez1. 1Centro Oncologico Estatal ISSEMyM, Toluca de Lerdo, Mexico.

Background: Genetic testing is not affordable in Mexico; average BRCA1&2 testing is $900, while average income in Mexico is $6423 per year. Genetic testing can be an economic burden for public-funded institutions. Current NCCN for genetic counselling and testing are broad to avoid missing patients at risk. Nonetheless, this approach could not be realistic in developing countries, thus we still must select our pts with risk evaluation models. This study describes the features of our BRCA mutation carriers.

Methods: New Breast Cancer (BrCa) cases were selected from nov2016 to march2018 according to NCCN criteria for genetic counselling. We gathered demographic, family and medical data. We also calculated the likelihood of carrying a BRCA mutation in each patient with one of two risk models: the Family History Assessment Tool (FHAT) or BRCAPRO. NGS analysis and MLPA for BRCA1&2 were performed in selected pts according to coverage, and availability of the test. The main target of the study was to compare the features of patients carrying a BRCA mutation (mBRCA) vs non-carriers, and the eligibility of the pts according to the risk models. Results: We offered genetic counseling to 180 pts based on personal or familial BrCa history. Median age was 44y (range 21-71). 18 (10%) pts had bilateral cancer, 2 (1.1%) had Br and ovarian Ca. 160 (88.9%) tumors were DCI, 10 (5.6%) pts didn't have cancer. 63 (35%) were TN, 87 (48.3%) were HR positive. All of them met criteria according to NCCN guidelines, but only 87 (48.3%) pts met criteria according to the risk evaluation models. 15 pts refused genetic testing because of lack of coverage. 63 (35.6%) pts had genetic testing, 21/64 (32.8%) of them were carriers of BRCA1 or BRCA2 mutation. TBNC was more frequent seen in BRCA mutated carriers vs non-carriers (p>0.024). Family History (FH) was seen in all but one carrier vs non-carriers (p>0.001), and all carriers met criteria by any risk model p>0.0001. Age was not statistically different between groups (p=0.472), but none carrier was younger than 30y. Conclusions: We confirm that the use of risk evaluation models are useful to identify mBRCA carriers, 32.8% in our cohort. Some features such as TNBC with family history were statistically different between carriers vs non-carriers. 23 pts were positive for risk model but were not mBRCA carriers, which underlines the need to offer larger genetic testing. Also, younger patients (21-30y) had more frequently triple positive phenotypes, and all were negative for BRCA testing; a TP53 testing would also needed. Unfortunately, multi-gene panels are more expensive than BRCA testing.
Multiple mutations in a single lineage: is it time for a shift in predictive testing?

Jennifer Scalia Wilbur¹, Jessica Laprise¹, Marcina Beaston¹ and Robert D Legare¹. ¹Women & Infants Hospital, Providence, RI.

Germline cancer genetic testing is a critical part of patient care influencing cancer risk reduction, prevention and now treatment decision-making. Single syndrome and mutation testing has been available for twenty years, however massively parallel sequencing technology has made multigene panel tests more readily available and at lower costs. Currently, it remains unclear if there is benefit related to panel testing in cancer families and patients already harboring a pathogenic mutation. We report 5 families found to harbor additional pathogenic mutations identified with multigene panel testing.

One Ashkenazi family was found to harbor both a founder and non-founder BRCA mutation in a single lineage. Four additional families were found to harbor a second mutation in either a novel breast/ovary cancer gene or in a gene related to an established cancer syndrome. All patients were either initially BRCA2 or PALB2 positive and were subsequently found to have a second mutation in either CHEK2, RAD51D, ATM, MUTYH or PMS2. In 2 cases, the secondary mutation either increased frequency and/or decreased start age of colonoscopy screening. Interestingly, 2 of the additional mutations were first reported as variants of uncertain significance later reclassified as likely pathogenic.

In all cases the traditional approach of single site/syndrome analysis for predictive testing would have failed to identify the second pathogenic mutation resulting in an underestimate of cancer risk in negative family members. Notably, the majority of secondary mutations were present within the same lineage as the known familial mutation. In 3 of 5 cases, the finding of a second mutation in already identified mutation carriers led to additional changes in medical management. As multigene panel testing becomes more accessible in both cost and provider acceptance, this case series illustrates the need to strongly consider use of multigene panel testing for relatives undergoing testing for known familial mutations regardless of family history, and ultimately indicating a role for re-testing established mutation carriers.
Risk reducing interventions among BRCA 1 and 2 female carriers in Newfoundland and Labrador: A provincial analysis

Melanie D Seal¹, Aimee Roebothan¹, Ashley Gabriel¹ and Lesa Dawson¹. ¹Memorial University, St. John's, NL, Canada.

Introduction
Germline mutations in the tumour suppressor genes BRCA 1 and 2 result in a significant increase in cancer predisposition. Female carriers can have up to a 50-70% chance of developing a breast malignancy in their lifetime and a risk of 20-40% for ovarian cancer. Management options for women with a BRCA mutation include screening with annual mammography and magnetic resonance imaging (MRI), prophylactic surgery and chemoprevention. There is substantial evidence that preventative strategies may reduce the risk of developing breast and ovarian cancer and in some cases improve survival.

Newfoundland and Labrador (NL) is the most easterly province in Canada with a population of 525,983. It is geographically and genetically isolated with the majority of residents from English and Irish ancestry. While no one single founder effect has been identified, geographically distinct mutations for both BRCA 1 and 2 have been described. The objective of this study is to characterize the population of BRCA mutation carriers in NL and to evaluate their uptake of risk reducing interventions.

Methods
All BRCA 1 and 2 carriers tested through the Provincial Medical Genetics program between 1996 - 2018 were captured. Inclusion criteria for this study were females ≥ 18 years of age residing in the province. Demographic, clinical history and information on uptake of risk reducing interventions were abstracted from the electronic medical record. Descriptive statistical analysis was performed.

Results
One hundred and sixty one women were identified that met inclusion criteria (38% of patients had BRCA1 and 62% had BRCA 2 mutations). Of those unaffected carriers eligible for mammography and MRI screening, only 58% were adherent in the last 18 months. Consultation with a medical or gynecological oncologist increased mammogram screening within the last 18 months to 71% compared with 29% of women who did not see an oncologist. MRI screening increased to 80% for those assessed by oncology versus 20% who did not. For those women who underwent prophylactic surgeries, 27% had bilateral mastectomies with the majority having breast reconstruction (>70%). Fifty two percent of carriers had bilateral salpingo-oophorectomies (BSO) at a median age of 45 years in BRCA 1 and 51 years in BRCA 2.

Fifty-three women had a diagnosis of breast cancer and 8 had ovarian cancer. In this cohort, most underwent genetic testing after their diagnosis of cancer (>80%). Median age at presentation of breast cancer was 44 years versus 54 years for ovarian cancer.

Conclusion
This study demonstrates that women with BRCA 1 and 2 mutations are not adequately availing of risk reducing interventions for breast and ovarian cancer. Furthermore, most patients with malignancy did not undergo genetic testing until after they were diagnosed with cancer. Patient focused research designed to explore factors which may contribute is planned. Consultation with an oncologist increased the likelihood of adherence to breast cancer screening. This highlights the importance of specialty care for patients with a hereditary predisposition to breast and ovarian cancer.
Multiple cancer susceptible genes sequencing in BRCA-negative breast cancers with high hereditary risk

Guan-Tian Lang¹, Xin Hu¹, Jin-Xiu Shi², Wei Huang² and Zhi-Ming Shao¹. ¹Key Laboratory of Breast Cancer in Shanghai, Fudan University Shanghai Cancer Center, Shanghai, China and ²Shanghai-MOST Key Laboratory of Health and Disease Genomics, Chinese National Human Genome Center at Shanghai, China.

**Background** Breast cancer susceptibility is strongly associated with a patient's hereditary background. Comprehensive BRCA mutation screening in our cancer center shows a lower BRCA mutation prevalence (9.1%) in Chinese breast cancer patients with hereditary risk. Multiple cancer susceptible genes sequencing can assist in discovering detrimental germline mutation in BRCA-negative breast cancers.

**Methods** From 2005-2014, BRCA-negative breast cancer patients with any two of the following risk factors were recruited: (1) pathological diagnosis of triple-negative breast cancer, (2) male breast cancer, (3) primary bilateral breast cancers in one individual, regardless of synchrony or asynchrony, (4) early-age onset breast cancer (less than or equal to 40 years of age at diagnosis), or (5) patients with a family history of breast and/or ovarian cancer (at least one first- and/or second-degree relative with breast cancer or ovarian cancer). A total of 384 Chinese subjects were screened by next-generation sequencing for 32 breast cancer associated susceptibility genes (APC, ATM, BARD1, BMPR1A, BRIP1, CDH1, CDK4, CDKN2A, CHEK2, EPCAM, MEN1, MET, MLH1, MRE11A, MSH2, MSH6, MUTYH, NBN, NF1, PALB2, PALLD, PMS2, PTCH1, PTEN, RAD50, RAD51C, RAD51D, RET, SMAD4, STK11, TP53, VHL). Mutations were classified as pathogenic/likely-pathogenic if they had a truncating, initiation codon or splice donor/acceptor effect, or if pathogenicity was demonstrated in published literature.

**Results** In total, we acquired 39 patients (10.2%) with pathogenic/likely-pathogenic germline mutations, including one carrying two distinct mutations. Major mutant non-BRCA genes were MUTYH (n=11), PTCH1 (n=7), RET (n=6) and PALB2 (n=5). Other mutant genes included TP53 (n=3), RAD51D (n=2), CHEK2 (n=1), BRIP1 (n=1), CDH1 (n=1), MRE11 (n=1), RAD50 (n=1) and PALLD (n=1). In addition, PTCH1 mutation carriers were found to be associated with the clinical features of triple-negative and early-age onset breast cancer.

**Conclusions** Among BRCA-negative breast cancer patients with high hereditary risk in China, 10.2% carried mutations in breast cancer associated susceptibility genes. MUTYH and PTCH1 had relatively high mutation rates (2.9% and 1.8%). Some clinical features might be associated with germline mutations of particular genes in breast cancer.

Key words germline mutation, BRCA-negative, hereditary breast cancer, multiple-gene sequencing
The complexity of germline panel testing: Cost, access and variant interpretation in an Irish context

Emily M O'Donovan1, Michael Farrell2 and David Gallagher3. 1Hermitage Medical Clinic, Dublin, Ireland; 2Mater Private, Dublin, Ireland and 3St James Hospital, Dublin, Ireland.

Objectives
Diagnostic germline genetic testing of single or multiple cancer predisposition genes is increasingly central to the care of women with breast cancer. Testing for mutations in BRCA1/2 has therapeutic relevance in perioperative and metastatic settings. Variants of uncertain significance (VUS) are identified in approximately 5-20% of tests. Single gene testing in the Rep. of Ireland occurs through 3 clinics using laboratories in England. Panel testing is offered through Color Genomics and Myriad Genetics. Color genomics offers a less expansive panel test. Panels have made variant interpretation a common clinical challenge. We investigated interpretation of 10 VUS in 3 laboratories.

Methods
We selected 10 patients who had VUS reported in BRCA1/2 in NHS laboratories. Further diagnostic testing for mutations in BRCA1/2 was subsequently completed using BRACAnalysis on stored DNA from these individuals. Patients were re-contacted and offered Color panel testing for mutations in 30 genes. Previous test reports were not provided to either company. A review of all 10 BRCA1/2 VUS was performed on ClinVar database.

Results
Two VUS in BRCA1 and 8 VUS in BRCA2 were included in the study. Retesting was completed at a median time of 20mths (14-70mths) after the original testing. All 10 individuals underwent BRACAnalysis testing, only 7 had panel testing (2 did not make contact following calls/letters, 1 had left Ireland). ClinVar classified 3 variants as benign, 2 likely benign, 2 VUS and 2 pathogenic (1not on ClinVar). All 10 VUS were re-classified by Myriad and Color. One result was deemed 'pathogenic' by Color and 'suspected deleterious' by Myriad (pt 9, table 1). Panel testing identified two additional VUS: an MSH6 and a RAD51.

**Conclusions**

All 10 VUS in BRCA1/2 were reclassified with additional testing by two commercial laboratories at a later date. The results of this testing by two different companies are clinically concordant. Panel testing identified 2 additional VUS in potentially clinically relevant genes. Less expansive testing increases access to germline genetic testing but requires responsible interpretation.
Improved patient compliance and genetic screening efficiency following implementation of an electronic pedigree survey (PROGENY)

Terah M Hennick¹, Taimoor Khan¹, Rebecca Moroose² and Ryan Bisson². ¹University of Central Florida College of Medicine, Orlando, FL and ²University of Florida Health Cancer Center - Orlando Health, Orlando, FL.

Introduction
Patients referred for genetic counseling do not consistently complete a family history questionnaires (FHQ), which is required before scheduling a genetic counseling appointment (GCA). A paper survey has traditionally been used to collect this FHQ data. This requires the genetic counselor to manually input the patient's FHQ information into a pedigree generator prior to scheduling their GCA, thereby delaying the genetic screening process. Some genetic counseling centers have switched from using this paper survey to a web-based pedigree-generator, like PROGENY, for collecting patient's FHQ data. No literature to date has evaluated the impact of this change on patient compliance with completing the required FHQ, the genetic screening process, or patient outcomes. This study assesses changes in patient compliance and genetic screening efficiency with the implementation of PROGENY compared to traditional surveying as a means of collecting FHQ data.

Hypothesis
More patients will complete the FHQ and GCA and there will be reduced time between patient referral and completion of the FHQ and GCA with the use of PROGENY compared to the traditional paper survey.

Methods
This is a retrospective chart review of patients referred for genetic counseling six months before and after implementation of PROGENY. Independent t-tests assuming unequal variances were conducted using JMP to compare genetic screening efficiency with and without the use of PROGENY.

Results
This study found that 41% more patients completed the FHQ and 25% more patients completed a GCA when using PROGENY. Further, there was a statistically significant reduction in the time between referral and completion of the FHQ ($t(311)=9.14$, $p<.0001$) as well as the GCA ($t(280)=3.04$, $p<.0001$). Specifically, the average time for patients to complete the FHQ was 84.45 days faster with PROGENY and the time for patients to complete a GCA was 34.83 days faster with PROGENY than without PROGENY.

Conclusions
These results support our hypothesis and suggest that utilizing PROGENY in collecting patient FHQ data correlates with improved patient compliance and genetic screening efficiency. Future work should investigate how quality improvement such as this impacts patient outcomes, such as the timeliness of finding an actionable genetic mutation and detecting cancerous and precancerous lesions. Some limitations of this study include high variability. This is likely due to factors such as appointment cancellations, geneticist availability and workload, and patient age, ethnicity, gender, and socioeconomic status. Future work should assess the impact of these factors on variables such as patient compliance and efficiency of the genetic screening process.
Genetics insights into hereditary cancer risk in the Brazilian population

1Universidade Federal Fluminense and Universidade Estadual do Rio de Janeiro, Rio de Janeiro, Brazil; 2Color Genomics, Burlingame, CA and 3Oncologia D’Or/ Grupo Acreditar, Federal District, Brazil.

Introduction: At least 5–10% of cancers are associated with germline mutations in oncogenes and tumor suppressor genes. The identification of individuals with these germline mutations and subsequent cancer risk is crucial for preventive and therapeutic options and represents an opportunity for cancer risk reduction. In Brazil, there are limited specialists devoted to hereditary cancer diagnosis and follow-up, and as a result the distribution of germline mutations and cancer risk in the Brazilian population is not well understood. Here, we analyze the results of germline genetic testing for hereditary cancer risk in a Brazilian cohort.

Methods: We describe the demographics and genetic results of 758 Brazilians who were referred by a physician to receive genetic testing for hereditary cancer risk. The test consisted of next generation sequencing (NGS) based assessment of 19 or 30 genes associated with hereditary cancer risk. The relatedness of individuals was not assessed in this study.

Results: In this cohort the overall pathogenic rate was 20.8%. Pathogenic variants were most commonly identified in BRCA1 (23.8%) and BRCA2 (22.0%), followed by MUTYH (11.9%), CHEK2 (10.7%), TP53 (8.9%), PALB2 (5.4%), ATM (3.0%), MLH1 (1.8%), MSH2 (1.8%), PMS2 (1.8%), RAD51D (1.8%), APC (1.2%), BARD1 (1.2%), MITF (1.2%), MSH6 (1.2%), RAD51C (1.2%), BRIP1 (0.6%), and NBN (0.6%). The VUS rate was 25.3%. The average age of the cohort was 47.8 years and positive rate by age group was: 18-24 (29.4%), 25-34 (29.1%), 35-44 (18.1%), 45-54 (21.9%), 55-64 (17.7%), 65 or older (18.8%). Individuals in this study self-reported their ancestry: Unknown (34%), Caucasian (29%), No answer (21%), Multiple Ethnicity (4%), Hispanic (4%), Native American (3%), African (3%), Ashkenazi Jewish (1%), and Asian (0.5%). A total of 435 (57.4%) individuals reported a personal history of cancer. Of the people who did not have a personal history of cancer the overall pathogenic rate was 12.1%. A total of 10 (1.3%) individuals were found to carry two concurrent pathogenic variants in different genes.

Conclusions: This is one of the first multi-gene panel studies of hereditary cancer risk conducted in the Brazilian population on individuals with a diverse set of clinical indications; nearly half of the people tested didn't have a personal history of cancer yet there was still a significant rate of mutation in that unaffected group highlighting an opportunity for earlier intervention. BRCA1 and BRCA2 accounted for the majority of genetic alterations, however mutations in TP53 were more frequent than in other populations, which is consistent with the presence of a known Brazilian founder mutation in TP53. The VUS rate of 25.3% was a little higher than the VUS rate (18.4%) we have observed previously when reporting on a largely caucasian cohort, indicating a need to increase testing in diverse population to help resolve variant classification.
Using whole genome sequencing and somatic mutation signatures to unravel insight into familial breast cancer aetiology

Peter Simpson¹, Katia Nones², Julie Johnson¹, Felicity Newell², Ann-Marie Patch², Heather Thorne³, Stephen Kazakoff², Xavier De Luca¹, Michael Parsons², Kaltin Ferguson¹, Lynne Reid¹, Amy McCart Reed¹, Sriganesh Srihari¹, Vanessa Lakis², Aimee Davidson², Pamela Mukhopadhyay², Oliver Holmes², Qinying Xu², Scott Wood², Conrad Leonard², Jonathan Beasley², Andrea Degasperi⁴, Serena Nik-Zainal⁴, Mark Ragan¹, Amanda Spurdle⁵, Kum Kum Khanna¹, Sunil Lakhani¹, John Pearson², Georgia Chenevix-Trench⁵ and Nicola Waddell².

¹The University of Queensland, Brisbane, Australia; ²QIMR Berghofer Medical Research Institute, Brisbane, Australia; ³Peter MacCallum Cancer Centre, Melbourne, Australia; ⁴University of Cambridge, Cambridge, United Kingdom and ⁵Westmead Institute for Medical Research, Sydney, Australia.

Approximately 10-15% of breast cancers are associated with a strong family history of disease. Pathogenic variants in BRCA1, BRCA2 or other moderate to highly penetrant susceptibility genes (e.g. TP53, ATM, CHEK2, PALB2 and PTEN) account for a number of breast cancer families. However, for over 50% of families the underlying genetic contribution to their risk remains unknown (termed here as non-BRCA1/2). This has a profound impact for how individuals and their families are managed in the clinic. We applied whole genome sequencing (WGS) to determine whether somatic mutation analysis can reveal insight into the aetiology of familial breast cancer. The full repertoire of somatic mutations was evaluated in 26 BRCA1, 22 BRCA2 and 32 non-BRCA1/2 tumours; including SNPs, indels, copy number changes and structural rearrangements, and mutational signatures. Genomes were also analysed using the HRD Index and HRDetect, as predictors of homologous recombination deficiency. BRCA1, BRCA2 and non-BRCA1/2 tumours exhibited a different burden of mutations, a different spectrum of mutational signatures and different telomere length. Based on collective patterns of mutation signatures, tumours were classified as 'BRCA1-like', 'BRCA2-like' or 'non-BRCA1/2-like' with a 15% rate of tumour re-classification from their original clinical BRCA status. The results demonstrate the power of WGS to differentiate between BRCA1 and BRCA2 driven tumours; in the identification of double-pathogenic germline mutation carriers based on the resulting somatic mutation signature; and in the interpretation of BRCA unclassified variants. WGS of tumour genomes reveals fascinating insights into tumour aetiology and could compliment current genetic testing of breast cancer families.
Development and validation of a polygenic score to predict breast cancer risk in unaffected Hispanic women negative for mutations on a multi-gene hereditary cancer panel

Elisha R Hughes¹, Susanne Wagner¹, Dmitry Pruss¹, Shannon K Gallagher¹, Brad Swedlund¹, Katrina Bulka¹, Ryan Hoff¹, Srikanth Jammulapati¹, Brian Morris¹, Thomas Perry¹, Jerry S Lanchbury¹ and Alexander Gutin¹. ¹Myriad Genetics, Inc, Salt Lake City, UT.

Background: Breast cancer (BC) is the most commonly diagnosed cancer and the leading cause of cancer-related death among Hispanic women in the United States. For women of European ancestry, genome-wide association studies (GWAS) have identified common variants, primarily single-nucleotide polymorphisms (SNPs), that individually confer modest risk but together explain a significant proportion of genetic BC predisposition. For Hispanic women, the genetic contribution of SNPs to BC risk is not well understood. In these studies, we aim to develop and validate a polygenic score to improve risk assessment for Hispanic women who test negative for mutations in known BC susceptibility genes.

Methods: Genotypes and clinical histories were collected from consecutive development and validation cohorts of patients referred for hereditary cancer testing. Study subjects include women who report strictly Hispanic or Latin American ancestry, and who test negative for mutations in 11 genes associated with breast cancer (BRCA1, BRCA2, TP53, PTEN, STK11, CDH1, PALB2, CHEK2, ATM, NBN, BARD1).

Based on a development cohort ascertained through June 2017, we evaluated an 86-SNP Residual Risk Score (RRS) that was previously developed and validated for women of European ancestry. In the same cohort we are developing a Hispanic Residual Risk Score (HRRS) optimized for women of Hispanic ancestry. BC associations of individual SNPs are being established through meta-analysis of the development cohort and published Hispanic studies.

Multivariate logistic regression models were used to evaluate the 86-SNP RRS, and were the primary statistical tool for evaluation of individual SNPs and candidate polygenic scores. All models included personal/family cancer history and age as independent variables. P-values are based on likelihood ratio test statistics, and reported as two-sided. The development and validation studies are being conducted according to a protocol approved by the Quorum Institutional Review Board.

Results: The development cohort included 5,454 Hispanic women, 24% of whom reported a personal history of BC. The 86-SNP RRS was significantly associated with a personal history of BC after accounting for personal and family cancer history (p<10⁻¹⁹) with odds ratio per unit standard deviation 1.39 (95% CI = 1.30-1.50). To date, more than 5,000 Hispanic women have been ascertained for inclusion in the validation cohort. Results comparing discriminatory accuracy of the RRS and the HRRS will be presented.

Conclusions: The implementation of a clinically validated polygenic score may improve risk assessment and medical management of Hispanic women who test negative for monogenic BC mutations. The HRRS will be validated in an independent study population according to a pre-specified statistical analysis plan.
Breast cancer diagnosed in young women ≤ age 35: Importance of germline mutations and cancer subtypes on treatment outcomes

Michaela L Tsai¹, Monica Knaack¹, Parker Martone², Janet Krueger¹, Shari R Baldinger¹, Tamera J Lillemoe¹, Barbara Susnik¹, Erin Grimm¹, Natasha Rueth¹ and Karen K Swenson¹. ¹Allina Health System, Virginia Piper Cancer Institute, Minneapolis, MN and ²University of Minnesota, Minneapolis, MN.

Background: While breast cancer is rare in women ≤ age 35, patients in this age group are more frequently diagnosed with aggressive cancer subtypes and pathologic germline mutations in cancer susceptibility genes than older patients. Higher recurrence and mortality rates in young breast cancer patients may be related to differences in tumor biology, pathologic mutation status, host characteristics or treatment.

Specific Aims: The primary purpose of this retrospective study was to evaluate germline mutation status, breast cancer subtypes, and other associated risk factors that may impact recurrence-free and overall survival in patients diagnosed with breast cancer at age ≤ 35.

Methods: This was a retrospective review of all breast cancer cases diagnosed in women ≤ age 35 (n= 306) at Allina Health facilities from the years of 2000 – 2017. We collected information on germline mutation status, histopathologic tumor characteristics (including grade, hormone receptor status, human epidermal growth factor receptor 2 [HER2] status, molecular subtype), pregnancy-associated cancers (within a year of diagnosis), treatment, and recurrence-free and overall survival in this cohort. Kaplan Meier analyses were conducted for recurrence-free and overall survival by mutation status and molecular subtype.

Findings: With a mean follow-up of 6.5 years, the overall survival rate was 88.2%, with a recurrence-free survival rate of 85.2%. A total of 69.3% of patients obtained genetic testing, and 26.9% of those patients had high-risk pathologic mutations, particularly breast cancer gene (BRCA)1 and BRCA2. There were no significant differences in recurrence-free or overall survival between patients with high-risk genetic mutations as compared to those with low-risk/no mutations. However, the definitive surgery and chemotherapy use did vary by mutation status; patients with high-risk mutations were more likely to have bilateral mastectomies and receive chemotherapy (p = 0.002 and p = 0.04, respectively). Kaplan Meier analysis showed that survival was impacted by breast cancer molecular subtype; patients with Luminal B cancer had the lowest overall survival followed by HER2 positive and triple negative cancers (p = 0.05). Other factors associated with decreased survival included cancer stage, angiolymphatic invasion, tumor grade, and pregnancy-associated diagnoses (within a year of diagnosis).

Conclusions: Our study shows that patients with high-risk genetic mutations (primarily BRCA1 and BRCA2) were more likely to receive chemotherapy and bilateral mastectomies. Patients with high-risk mutations had similar rates of survival and recurrence-free survival compared to patients without mutations in this study despite an increased risk of overall recurrence and subsequent cancer. In spite of their young age at diagnosis, nearly a third of patients in this study did not receive genetic testing; these results may have impacted treatment and outcomes. Patients diagnosed with Luminal B subtype had the lowest overall survival. Pregnancy-associated breast cancer diagnoses were associated with decreased survival in this age cohort.
Exome sequencing in high breast and ovarian cancer incidence families which lack detectable mutations in established cancer susceptibility genes

Paraic A Kenny¹, Megan A Girtman¹, Jake A Deviley¹, David R Meier¹, Cullen R Vos¹, Craig S Richmond¹ and Kristopher A Lofgren¹. ¹Gundersen Medical Foundation, La Crosse, WI.

At our center, a standard 25 gene panel has proved useful for the identification of pathogenic germline mutations in many families with a high penetrance of breast and ovarian cancer, yet there remain several families with very high cancer incidence but from whom these assays have not identified pathogenic alleles. To attempt to define the genetic mechanism of susceptibility in such cases, are conducting germline whole exome sequencing in affected individuals. Here we describe the identification of strong candidate susceptibility variants in two such families. Both variants cause loss-of-function of DNA repair genes not previously implicated in breast cancer, but which share properties with genes with known roles in maintenance of genome integrity. In one individual, with a personal history of ovarian cancer and two independent breast tumors, we identified a novel point mutation in POLD2 which introduces a mutation at a residue which is biochemically conserved in all animal species thus far sequenced. In the second individual, a frameshift mutation was detected in ERCC4. In both cases, the variants found have not been observed in large exome datasets (e.g. ExAC) or reported in ClinVar. Our study highlights the potential utility of whole exome sequencing as a discovery tool in those families with high cancer incidence yet which lack mutations in known hereditary cancer predisposition genes.
An association of PALB2 T1100T(3300T>G) polymorphism with breast cancer in the KYRGYZ ethnic group

Aigul Semetei Kyzy¹, Emil Makimbetov¹, Indira Kudaibergenova² and Jainagul Isakova³. ¹Kyrgyz-Russian Slavic University, Bishkek, Kyrgyzstan; ²Kyrgyz State Medical Academy, Bishkek, Kyrgyzstan and ³Research Institute of Molecular Biology and Genetic, Bishkek, Kyrgyzstan.

**Background:** PALB2 (a partner and localizer of BRCA2) is an important regulator of homologous recombination and a key-component of DNA excision repair. PALB2 was firstly characterized in patients with Fanconi anemia, complementation group N, and then it has been discovered that heterozygosity for loss of function mutations at PALB2 increases risk of breast cancer 2-to 6-fold. Inherited PALB2 mutations associated with increased risks of breast cancer (BC) have been identified in families from many parts of the world. An association of PALB2 with BC has never been tested in the Kyrgyz ethnic group.

**Methods:** This was a case-control study of 201 women of the Kyrgyz ethnic group with a morphologically verified breast cancer (N=99) and 102 controls age-, ethnicity-matched with BC cases. The mean age of the patients was 53 years (24 -74, SE mean = 0.967, STD = 9.81). 63 of 99 BC patients had family history of breast cancer and uterine cancer. The extraction of DNA was carried out from venous blood. The genotyping was performed by using the method of polymerase chain reaction and restriction fragment length polymorphism.

**Results:** In our study PALB2 gene presented with the TT (95%) genotype and the heterozygous TG (5%) genotype. We have observed a statistically significant difference between occurrence of both genotypes in two different groups: patients with T1-T2 (primary tumor's size is 2-5cm across) and patients with T3, T4 (primary tumor's size is larger than 5cm across) (according to TNM classification of breast cancer). The genotype TT occurred in 76.5% of BC cases in patients with T1-T2, and in 23.4% of BC cases in patients with T3-T4, whereas the heterozygous genotype TG occurred in 25% of BC cases in patients with T1-T2, and in 75% of BC cases in patients with T3-T4 (p=0.02, z-ratio=2.318).

**Conclusion:** The results of our study suggest that the heterozygous TG genotype of PALB2 T1100T(3300T>G) polymorphism can be associated with primary tumor's size larger than 5cm across (corresponds to T3-T4) and consequently related to advanced stages of BC. The TT genotype can be associated with primary tumor's size 2-5cm across (corresponds to T1-T2), and related to early stages of BC.
Pharmacodynamic and circulating tumor DNA evaluation in a phase I study of GDC-0927, a selective estrogen receptor antagonist/degrader (SERD)

Jill M Spoerke¹, Anneleen Daemen¹, Ching-Wei Chang¹, Jennifer Giltnane³, Ciara Metcalfe³, Maura N Dickler⁵, Aditya Bardia³, Jose Alejandro Perez Fidalgo⁴, Ingrid A Mayer⁵, Valentina Boni⁶, Eric P Winer⁷, Erika P Hamilton⁸, Meritxell Bellet⁹, Ander Urruticoechea¹⁰, Antonio Gonzalez Martin¹¹, Javier Cortes¹², Miguel Martin¹³, Mary Gates¹, Sravanthi Cheeti¹, Jill Fredrickson¹, Xiaojing Wang¹, Lori S Friedman¹, Lichuan Liu¹, Robert Li¹, Iris T Chan¹, Lars Mueller¹, Sandra Milan¹, Jennifer Lauchle¹, Eric W Humke¹ and Mark R Lackner¹⁴. ¹Genentech, Inc., South San Francisco, CA; ²Eli Lilly, Indianapolis, IN; ³Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; ⁴Hospital Clinico Universitario de Valencia, INCLIVA, Valencia, Spain; ⁵Vanderbilt University Medical Center, Nashville, TN; ⁶START Madrid-CIOCC, Hm Hospital Sanchinarro, Madrid, Spain; ⁷Dana Farber Cancer Institute, Boston, MA; ⁸Sarah Cannon Research Institute / Tennessee Oncology, Nashville, TN; ⁹Hospital Universitari Vall d’Hebron and Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Spain; ¹⁰Onkologikoa, San Sebastian, Spain; ¹¹Clinica Universidad de Navarra, Madrid, Spain; ¹²Ramon y Cajal University Hospital, Madrid, Spain; ¹³Hospital General Universitario Gregorio Marañón, Madrid, Spain and ¹⁴Ideaya Biosciences, South San Francisco, CA.

Background: Modulation of estrogen activity and/or synthesis is the mainstay therapeutic strategy in the treatment of ER positive breast cancer. However, despite the effectiveness of available endocrine therapies, many patients ultimately relapse or develop resistance to these agents via estrogen-dependent and estrogen-independent mechanisms, including mutations in ESR1 affecting the ER ligand binding domain that drive ER-dependent transcription and proliferation in the absence of estrogen. Based on preclinical and clinical data, SERDs are expected to be effective in patients harboring ESR1 mutations. Biomarker analysis was performed on plasma and tumor samples from the Phase I study of GDC-0927 in metastatic breast cancer (Dickler et al, SABCS 2017) with the goal of evaluating activity in both ESR1 mutant and wildtype tumors, and to assess ER pathway modulation.

Methods: Hotspot mutations in ESR1, PIK3CA, and AKT1 were analyzed in baseline, on-treatment and end of treatment plasma derived circulating tumor DNA (ctDNA) using the BEAMing assay in patients treated at multiple dose levels of GDC-0927. A subset of samples was analyzed with Foundation Medicine’s next generation sequencing ctDNA assay (FACT), which covers genomic alterations in 62 commonly altered genes. Paired pre- and on-treatment biopsies were collected to assess ER pathway modulation. ER, PR, and Ki67 protein levels were analyzed by immunohistochemistry. Gene expression analysis was performed using Illumina’s RNA Access library preparation kit followed by paired-end (2x50b, 50M reads) sequencing on the HiSeq.

Results: Baseline and on-treatment plasma samples were available for 40 patients. ESR1 and PIK3CA mutations were observed in 52% and 33% of patient baseline samples, respectively (BEAMing method). Mutant allele frequencies (MAF) generally declined in the first on-treatment samples collected for both ESR1 (16 out of 21 samples) and PIK3CA (7 out of 12 samples). The majority of the reductions were greater than 95% relative to baseline. Increases in ESR1 MAFs were observed in later time-points and were not associated with any particular ESR1 mutation. There were six instances for which an ESR1 mutation was detected in an on-treatment sample that was not detected in the baseline sample, three at L536P and one each at D538G, L536H, and S463P, and four out of six with MAFs close to the limit of detection. The FACT assay also detected alterations in CDH1, NF1, PTEN, and TP53 in baseline samples. The relationship between MAF changes and clinical benefit to GDC-0927 will be presented. A predefined, experimentally-derived set of ER target genes were evaluated in pre- and on-treatment tumor biopsy pairs from six patients. Four of the six patients showed evidence of suppression in ER pathway activity, one patient treated at the 1000 mg dose level and three at the 1400 mg dose. The degree of pathway suppression was associated with pre-treatment pathway levels and decreases of ER and Ki67 protein levels.

Conclusions: We report here evidence of consistent reduction of ESR1 and PIK3CA ctDNA in patients treated with GDC-0927. ER pathway suppression was observed at both the transcript and protein level confirming pharmacodynamic activity of the SERD.
Recurrence of $ESR1$ fusions in primary tumors; a promising predictive factor for outcome to first-line endocrine therapy?

Anieta M. Sieuwerts$^1$, Silvia R. Vitale$^1$, Manouk Bos$^1$, Stefan Sleijfer$^1$ and John WM. Martens$^{1,2}$. $^1$Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, Netherlands; $^2$Cancer Genomics Netherlands, Rotterdam, Netherlands and $^3$University of Catania, Catania, Italy.

Introduction:
While fusion genes have been identified and are being utilized as prognostic and predictive markers in various types of cancer, their relevance still needs to be established and verified for breast cancer. Recently, recurrent estrogen receptor alpha ($ESR1$) fusion genes have been identified as putative endocrine resistance markers, but their predictive value for response to endocrine therapy has not yet been independently validated. Here we studied the presence of fusions of $ESR1$ exon 2 with exons 1 to 11 of $CCDC170$, resulting in constitutively activated $CCDC170$, of $ESR1$ exon 4 with $AKAP12$, a putative tumor-suppressor gene, and $ESR1$ exon 1 with $C6orf211/ARMT1$, a methyltransferase and their association with outcome in a large cohort of $ESR1$-positive metastatic breast cancer patients.

Methods:
Fusion gene mRNA levels were measured in 307 $ESR1$-positive primary tumors by quantitative reverse transcriptase PCR (RT-qPCR). If the RT-qPCR generated a positive Cq value, the expected fusion gene product sizes were validated by MultiNA. All patients in this study were hormone-naive and all experienced a recurrence and subsequently received 1st-line endocrine therapy. The association of the presence of $ESR1$ fusion genes in the primary tumor with disease-free interval (DFI) before, and progression-free survival (PFS) up to 36 months after start with 1st-line tamoxifen (n=219) or aromatase inhibitors (n=88), were evaluated.

Results:
74 patients (24.1%) experienced a disease recurrence within one year after removal of the primary tumor (mean DFI; 34.8 months) and 257 patients (83.7%) progressed on 1st-line endocrine therapy within 3 years (mean PFS; 12.5 months).

For the tamoxifen cohort, $ESR1$-$CCDC170$ fusion transcripts were found in 84 patients, of which fusions restricted to exon 1, 4, 6, 10 and 11 of $CCDC170$ were present in 18 patients who all but one progressed within 3 years (mean PFS 9.1 months). Of note, overall, these 18 patients also had a reduced DFI. Similarly for the 7 patients with $ESR1$-$AKAP12$ fusions and the one patient with an $ESR1$-$ARMT$ fusion; all these patients progressed within 3 years. But in contrast to the $ESR1$-$CCDC170$ fusion positive patients, these patients had a prolonged DFI (see Table).

Similar observations were made for the smaller AI cohort, though with the - with respect to their predictive value - most relevant $ESR1$-$CCDC170$ fusions restricted to exon 4, 5, 6 and 10 of $CCDC170$ and here we now also observed a decreased DFI for the 7 patients with $ESR1$-$AKAP12$ and the 3 patients with $ESR1$-$ARMT1$ fusions (see Table).

Conclusion:
Measuring recurrent $ESR1$ fusions in primary breast cancer might become a promising tool to identify patients with intrinsic resistance to endocrine therapy or aggressive disease biology. Importantly however, which fusions are relevant appears to depend on the type of endocrine therapy given.
Measurement of on-treatment proliferation biomarkers in nodal metastasis improves prediction of endocrine therapy response using the EA2ClIn test

Arran K Turnbull1, Sarah Mok1, Carlos Martinez-Perez1, Anu Fernando1, Lorna Renshaw2, Jane Keys2, Andrew H Sims1 and J Michael Dixon2. 1Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinuburgh, United Kingdom and 2Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom.

Background: The majority of patients with early-stage estrogen receptor positive (ER+) breast cancer (BC) are treated with adjuvant endocrine therapy (ET) after surgery to reduce the risk of recurrence. Recently, we have developed and validated an immunohistochemistry (IHC) based assay (EndoAdjuvant2 Clinical; EA2Clin) that measures pre-treatment IL6ST level together with clinical variables and on-treatment MCM4 to assess proliferation. We have previously shown that it can accurately identify responders and non-responders to ET and predicts recurrence-free survival (RFS) and BC-specific overall survival (BCSS). We postulated that measuring on-treatment proliferation in lymph node metastases (LN+) rather in the primary cancer might further improve the accuracy of the test for these patients. The aim was to test and validate this in cohorts of pre- and post-menopausal women (preMW & PMW) treated with preoperative ET (tamoxifen (T), fulvestrant (F), letrozole (L) or anastrozole (A)) and subsequent adjuvant ET.

Methods: Cohorts: (1) 137 PMW with ER+ BC, 59 were LN+, treated with neoadjuvant L (median duration 4.8 months, range 1-33), then surgery followed by adjuvant L (n=109) or other ET (n=28); (2) 148 PMW with ER+ BC, 55 were LN+, treated with 2 weeks of preoperative L (n=76) or A (n=72), then surgery followed by adjuvant L (n=69) or T (n=79); (3) 52 preMW with ER+ BC, 24 were LN+, treated with 2 weeks of preoperative T (n=26) or 1x750mg dose of F (n=26), then surgery followed by adjuvant T. All LN+ patients had sentinel node biopsies or clearance. The median follow-up was 6.5 years (cohort 1), 6.3 years (cohort 2) and 10.2 years (cohort 3).

EA2Clin: Patients are classified as:
· Low risk: ER+ and LN-negative and <2cm or pre-treatment IL6ST 2+/3+ (IHC) and post-treatment MCM4 in the primary has <20% positive nuclear staining.
· High risk: ER+ LN+ grade 3 BCs >2cm or pre-treatment IL6ST is 0 or 1+, or IL6ST is 2+ or 3+ and MCM4 in the primary has >10% positive nuclear staining.

EA2ClIn uses the post-treatment level of MCM4 in the nodes, rather than the primary cancer.

Results: In cohort 1, EA2Clin (using primary tumour MCM4) was significantly associated with both RFS (P=0.0003, HR=13.17, 95%CI=5.48-13.61) and BCSS (P=0.005, HR=11.91, 95%CI=8.73-31.42). The 5 and 10 year actuarial recurrence rates were 5%/5% and 48%/64% for the low and high-risk groups respectively. In the same cohort, using the MCM4 level in the node (EA2ClIn) there was an even more significant association with both RFS (P<0.00009, HR=18.16, 95%CI=12.59-19.46) and BCSS (P=0.002, HR=12.93, 95%CI=5.43-25.62). The 5 and 10 year actuarial recurrence rates were 0%/0% and 48%/72% for the low and high-risk groups respectively. Further validation of EA2ClIn in cohorts 2 and 3 is underway.

Discussion:
· Direct measurement of on-treatment proliferation biomarkers in LN metastases improves prediction of outcomes to ET in women with BC.
· This tests identifies a group of low risk women that are node negative and node positive with a 100% RFS and BCSS.
· This is the most impressive predictive test for patients with ER+ breast cancer yet developed.
Anti-proliferative effect of oral metronomic vinorelbine (mVNB) in PAM50 Luminal/HER2-negative early breast cancer (SOLTI-1501 VENTANA): A randomized, three-arm, window-of-opportunity study

Aleix Prat1,2,3, Barbara Adamo1, Tomás Pascual1,2,3, José A Perez Fidalgo4, Salvador Blanch5, Noelia Martínez5, Patricia Gomez Pardo6, Ana Lopez Gonzalez6, Laura Murillo Jas06, Kepe Amillano10, Maria Vidal1, Laia Paré2,3, Jordi Canes2, Patricia Galvan1,3, Blanca Gonzalez Farre1, Vanesa Ortega Cebrián11, Xavier Gonzalez2,12, Meritxell Bellet Ezquerra13, Patricia Villagrasa2 and Eva Ciruelos14. 1Hospital Clinic i Provincial de Barcelona, Barcelona, Spain; 2SOLTI Breast Cancer Research Group, Barcelona, Spain; 3IDIBAPS, Barcelona, Spain; 4Hospital Clínico Universitario de Valencia / INCLIVA / CIBERONC, Valencia, Spain; 5Fundación Instituto Valenciano de Oncologia, Valencia, Spain; 6Hospital Universitario Ramón y Cajal, Madrid, Spain; 7Vall d’Hebron University Hospital, Barcelona, Spain; 8Complejo Asistencial Universitario de León, Leon, Spain; 9Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain; 10University Hospital St. Joan de Reus, Reus, Spain; 11Hospital General de Granollers, Granollers, Spain; 12Instituto Oncológico Dr. Rosell / Hospital General de Catalunya, Barcelona, Spain; 13Vall d’Hebron University Hospital / Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Spain and 14Hospital Universitario 12 de Octubre, Madrid, Spain.

BACKGROUND: The anti-proliferative effect of mVNB alone or in combination with endocrine therapy in patients with hormone receptor-positive/HER2- breast cancer (BC) has been scarcely addressed.

METHODS: Postmenopausal women with untreated stage I-III BC were randomized (1:1:1) to receive 3 weeks of letrozole (LTZ) 2.5mg/day, oral mVNB 50mg 3 days/week or the combination. The 1st objective was to evaluate, within PAM50 Luminal A/B disease, if the anti-proliferative effect of mVNB+LTZ was superior to monotherapy. An anti-proliferative effect was defined as the mean relative decrease of the PAM50 11-gene Proliferation Score in each arm. 2nd objectives included safety and the comparison of the anti-proliferative effect between arms. An unplanned analysis of stromal tumor infiltrating lymphocytes (sTILs) was performed. PAM50 analyses were performed using the nCounter®-based Breast Cancer 360™ panel. Changes in the expression of 790 genes/signatures tracking multiple biological processes from tumor cells and the microenvironment were evaluated within each arm using paired (surgery vs. baseline) univariate analyses. P-values were corrected for multiple comparisons using false discovery rate (FDR).

RESULTS: A total of 61 patients were randomized and 54 paired samples (89%) were analyzed. Main patient characteristics were mean age 67, mean tumor size 1.7 cm, stage I (55.7%) and grade 1-2 (90%). Grade 3 toxicities occurred in 3.3% of cases. Baseline samples were Luminal A (72.3%) or B (27.7%). The anti-proliferative effect of mVNB+LTZ (-73.2%) was superior to both monotherapy arms combined (-49.9%; p=0.001) and mVNB (-19.1%; p<0.001). The anti-proliferative effect of mVNB+LTZ (-73.2%) was higher compared to LTZ (-65.7%) but did not reach statistical significance (p=0.328). Across the mVNB+LTZ, LTZ and VNB arms, 413 (52.3%), 403 (51.0%) and 21 (2.6%) genes/signatures were found differentially expressed (FDR<5%) between baseline and surgery samples. Compared to mVNB+LTZ baseline samples, surgical samples showed higher expression of AP-1 transcription factor subunits FOS and JUN, inflammatory chemokines (e.g. CCL4 and IL6), stromal-related genes (e.g. CAV1 and stroma signature) and immune infiltration (e.g. CD8 T-cell signature) and lower expression of proliferation-related genes (e.g. MKI67 and UBE2C), estrogen receptor-signaling and Risk of Recurrence. Of the 413 genes found differentially expressed in surgical samples compared to baseline samples in the mVNB+LTZ arm, 108 (26.2%) were not found in the LTZ arm. Among them, high expression of LAG3, CD24, CD84 and CCR5. Under the microscope, sTILs (>10% at week 3) were observed in 6.6% (mVNB), 15% (LTZ) and 26% (mVNB+LTZ) of the cases. In tumors with ≤10% TILs at baseline, an increase in TILs was observed following LTZ (p=0.049) and mVNB+LTZ (p=0.012).

CONCLUSIONS: mVNB is well-tolerated and presents antiproliferative activity alone and in combination with LTZ. The increase of activated CD8 T-cells or TILs observed with LTZ+mVNB opens the possibility of studying combinations with immunotherapy. Further investigation comparing these biological results with other metronomic schedules or combinations is warranted.
Concordance of genomic alterations with targeted sequencing of circulating tumor DNA (ctDNA) and circulating tumor cells (CTC) in endocrine-resistant metastatic breast cancer

Francisco Ayala de la Peña1,2,3, Esther Navarro Manzano1,2,3, Maria Piedad Fernández Pérez1,2,3, Elena García Martínez1,3, Pilar de la Morena Barrio1,3, Alejandra Ivars Rubio1,3, Enrique González Billalabeitia1,3, Ana Fernández Sánchez1,3, Raul Teruel Montoya1,3 and Gema Marín Zafra1,2,3. 1Hospital G. Universitario Morales Meseguer, Murcia, Spain; 2Universidad de Murcia, Murcia, Spain and 3IMIB-Arrixaca, Murcia, Spain.

Background: Liquid biopsy has emerged as a valuable strategy for analyzing resistance biomarkers in advanced breast cancer. Differences in genomic alterations between CTC and cfDNA has been reported before and may reflect differences in the cell compartments of origin. Our aim was to determine the mutational concordance between CTC and cfDNA in luminal metastatic breast cancer (MBC) with different levels of endocrine resistance.

Methods: We evaluated the mutational spectrum in matched cfDNA and CTC samples of 38 patients with luminal (hormone receptors [HR] positive, HER2 negative) MBC. Using QIAmp Circulating Nucleic Acid Kit, cfDNA was isolated from plasma samples (5 mL), and from CTC samples obtained from plasma (7.5 mL). CTC were isolated by Epcam-based immune-magnetic enrichment and confirmed with AdnaTest Breast Cancer Detect (Epcam, Muc1, HER2). Sequencing of both cfDNA and CTC was performed using the Oncoming Breast cfDNA Assay (150 hotspots, 10 genes). Limit of detection range was 0.01-0.15%, with 92.1% cases equal or less than 0.1%. Concordance between mutational profile of CTC and cfDNA was analyzed and correlated with endocrine resistance and patient characteristics.

Results: Forty-seven patients with HR+ HER2- MBC were included, yielding enough cfDNA for analysis in 38 cases (80%), with isolation of CTC in 8 cases (16.7%). Rate of mutation detection in CTC was 87.5% (7/8), with TP53 mutations in all cases and no cases of ESR1 mutations; two cases of ERBB3 and PIK3CA mutations were found only in CTC, without a correlate in cfDNA. In cfDNA, genetic alterations were observed in 63.4% of cases, with 70.8% of TP53 mutations, 37.5% of PI3KCA mutations and 25% ESR1 mutations (2 D538G, 3 Y537S, 2 V392I). Average number of mutations was 2.28 in CTC and 1.96 in cfDNA, with a range of 1-4 in both cases. Concordance between cfDNA and CTC was low, with only 20% of CTC mutations simultaneously detected in cfDNA. CTC were only detected in cases with primary or secondary endocrine resistance. The percentage of patients with genetic alterations in cfDNA varied according to the degree of endocrine resistance (no resistance, 42.8%; secondary resistance, 65.2%; primary resistance, 75%), although the difference was not statistically significant. An association was found between the rate of detection of mutations in cfDNA and the response status (progression disease: 90.9%; stable disease: 57.1%; objective response: 33.3%) (p=0.04).

Conclusions: The low rate of CTC detection in HR positive MBC may limit its utility for guiding therapeutic decisions. However, the information provided by CTC sequencing does not completely overlap with the data provided by cfDNA, and may be complementary to cfDNA in endocrine-resistant MBC.
Does hormone expression by IHC predict ER pathway activity? An analysis in a metastatic breast cancer patient cohort

Soo-Ryum Yang¹, Anja van de Stolpe², Anne van Brussel², Henk van Ooijen², Alfiia Galimzianova¹, David M Cohn¹, Francisco Beca¹, Daniel L Rubin¹ and Kimberly H Allison¹. ¹Stanford University School of Medicine, Stanford, CA and ²Precision & Decentralized Diagnostics, Philips Research, Eindhoven, Netherlands.

Background: Immunohistochemistry (IHC) staining for ER and progesterone (PR) receptors in breast cancer tissue is the current standard for testing for eligibility for hormone targeted therapies. However, these markers are imperfect predictors of response, and ER/PR expression can be heterogeneous, especially in the metastatic setting. Within an adjuvant tamoxifen-treated ER positive patient group functional ER pathway activity was associated with improved patient outcome (Verhaegh et al, Cancer Research 2014). This study investigated how ER/PR staining correlates with ER pathway activity in a cohort of metastatic breast cancers.

Methods: Cases of metastatic breast cancer with variable reported ER expression by IHC were selected from the Stanford Pathology Database. Cases were scored by a breast pathologist for percent cellularity of sample, percent and intensity of ER and PR staining, and a qualitative rating of heterogeneity of staining. Digital slides were annotated for areas of cellularity to perform ER pathway activity analysis. Functional ER pathway activity was measured in a quantitative manner using a biologically validated method, based on Bayesian computational model inference of functional pathway activity from RT-qPCR measurements of mRNA levels of target genes of the pathway transcription factor, providing an ER Pathway Activity Score (PAS)(Verhaegh et al, Cancer Research 2014).

Results: A total of 64 samples were tested for ER/PR expression as well as for ER pathway analysis. Annotated tumor areas of 57 samples were used for measurement of ER PAS. 61.4% were ER expression high (defined as >50% ER IHC positive, mean 94.0%) and 38.6 % were ER low (defined as <50% ER IHC positive, mean 23.0%). ER high cases had higher mean ER PAS when compared to ER low cases (ER high, mean PAS 47.6, SD 19.2; versus ER low, mean PAS 19.4, SD 11.7; unpaired one-tailed 2-sample t-test p<0.001). Importantly, there was wide variation in ER PAS even in cases with high ER expression levels. PR levels did not correlate with ER PAS. Three cases had clustered areas with different ER expression levels within the tissue slide (heterogeneous cases), resulting in 7 separately analyzed areas; ER pathway activity was separately analyzed in these areas. ER PAS was remarkably similar across areas with variable ER staining, e.g. within one tissue slide, areas with 20% and 90% ER expression had nearly the same ER PAS.

Discussion: Grouping cases into high vs low ER IHC staining reveals expected differences in ER PAS. However, nuclear ER expression (IHC) levels may be an imperfect predictor of actual ER pathway activity on an individual case basis. Preliminary results on cases with regional heterogeneity for levels of ER IHC expression suggest that ER PAS is more homogenous than IHC levels. Clinical studies examining value of ER PAS to predict response to hormonal therapies are ongoing.
The significance of androgen receptor co-expression in ER+ metastatic breast cancer patients treated with palbociclib

Chrystal A Landry¹, Meng Ru¹, Shabnam Jaffer¹, Maya Dimitrova¹ and Amy Tiersten¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** The PALOMA-1 and PALOMA-3 studies demonstrated a significant progression-free survival (PFS) advantage for palbociclib, a CDK4/6 inhibitor, in combination with letrozole or fulvestrant in the first or second line setting compared to these therapies alone in estrogen receptor (ER)+, HER2-negative metastatic breast cancer (MBC). Recent studies have revealed preliminary efficacy signals for androgen receptor (AR) blockade in MBC, predominately in AR+, triple negative patients. We sought to further evaluate AR expression and its significance in ER+ MBC patients treated with palbociclib early in their metastatic treatment course.

**Methods:** A retrospective review identified 22 patients treated with palbociclib for ER+, HER2- MBC after its FDA approval between January 1st, 2015 and October 1st, 2016 at our center with available pre-treatment tumor samples for analysis. Records were reviewed and clinical characteristics for each patient were analyzed. Archival tumor tissue was tested for AR, phosphorylated retinoblastoma (pRb), CDK6, p16, and CyclinE1 by immunohistochemistry assay for each patient. For AR, nuclear staining >0% was considered positive. For all other IHC studies, intensity of staining >2+ or staining in >10% of cells was considered positive.

**Results:** The median age was 63.5 years (range 34-84); 23% were ≥ age 70. Our cohort was 35% African American, 60% Caucasian, and 5% Asian American. 64% of patients were post-menopausal and 59% had visceral metastases. 45% of patients were on their first line of treatment, 23% second line, and 32% third line. 68% of patients were on an aromatase inhibitor. Median follow up was 18.7 months (95% CI 13.9, 23.3 months). The AR was expressed in 59% of patients; 55% had expression ≥10% and 41% had expression ≥20%. AR+ patients were significantly more likely to experience event-free survival (EFS) (HR 0.26, p=0.01), with a median EFS of 18.8 months (AR- median EFS 5.4 months). AR expression was significantly associated with expression of pRb (100% of AR+ patients, p=0.02). CDK6, p16, and CyclinE1 expression were not associated with AR expression or EFS.

**Conclusions:** Our data show preliminary evidence of the significance of ER and AR co-expression in ER+, HER2- MBC. ER+ AR+ patients have significantly improved EFS when treated with palbociclib and endocrine therapy as compared with AR-, ER+ patients. There is evidence that AR expression is associated with pRB expression, which may represent a mechanism by which cell cycle inhibition with palbociclib is particularly efficacious in these patients. AR expression rates in ER+, HER2- MBC are significant, and may provide rationale for combining CDK4/6 inhibitors with AR targeting as a subsequent line of targeted therapy in these patients before cytotoxic chemotherapy is initiated. Further studies based on these results are underway.
Genetic landscape of prior and resistance to CDK4/6 inhibition in targeted NGS panel analysis of palbociclib or abemaciclib and endocrine versus placebo and endocrine

Junnan Xu¹, Tao Sun¹ and Xiaonan Wang². ¹Cancer Hospital of China Medical University, Shenyang, China and ²Nanjing Geneseeq Technology Inc., Nanjing, China.

Background: CDK4/6 inhibition combined with endocrine therapy is now a standard of care for advanced estrogen receptor (ER) positive breast cancer. Predictive genetic landscape and mechanisms of resistance to CDK4/6 inhibitors have not been described clearly because of limited evidence from clinical samples. We investigated the genetic landscape and mechanisms of resistance to CDK4/6 inhibitors (palbociclib or abemaciclib).

Methods: Using driver mutation targeted sequencing, we conducted longitudinal ctDNA analysis in 39 pairs of baseline of primary tumor and end of treatment or monitoring plasma samples. DNA were extracted and the genomic profiles were analyzed based on NGS.

Results: In our cohort, the most frequence mutations were PIK3CA (38.5%), TP53(17.9%), CCND1, ZNF703, FGFR1, MAP2K4, RB1, ARID1A, ATRX, DNMT3A. In five patients harboring RB1 mutations prior to CDK4/6 inhibitor, only one case occured progressing early with 4mos of PFS, and the others were 5.5+, 6.5+, 13.5+, 21+months, it represented different from pre-clinical results that RB1 mutation was associated with resistance to CDK4/6 inhibitor. Interesting, patients with PIK3CA/PTEN/AKT1 mutations (n=15) were likely sensitivity to CDK4/6 inhibitor than those (n=11) with wild type (median PFS: 17 mos vs. 9.5mos, P=0.046). In another cohort of everolimus, new driver mutations emerged in both FGFR1 and ERBB3 at end of everolimus and significantly disappeared in AKT1 mutation. Three patients used palbociclib after progress disease of everolimus, the prognosis were poor with PFS of 1, 6, 9 mos. Evolution of driver gene mutations was uncommon in patients progressing on CDK4/6 inhibitors treatment, but common in patients progressing on everolimus treatment.

Conclusions: De novo PIK3CA/PTEN/AKT1 mutations were likely better prognosis biomarkers with the treatment of CDK4/6 inhibitor. RB1 mutation are common and may not contribute to CDK4/6 inhibitor resistance differ from PALOMA3 ctDNA analysis. Our small sample finding indicate it may be a bad stragegy for CDK4/6 inhibitor after progress disease with mTOR inhibitor everolimus.
Feasibility of tracking plasma DNA mutation kinetics in estrogen receptor positive metastatic breast cancer using a novel digital PCR amplicon sequencing assay

Sunil Kumar¹, Daniel Lindsay¹, Brent Chen¹, Amy L Garrett¹, Xianming M Tan¹, Carey K Anders¹, Lisa A Carey¹ and Gaorav P Gupta¹. ¹University of North Carolina, Chapel Hill, NC.

Estrogen Receptor 1 (ESR1) gene mutations in estrogen receptor positive (ER+) metastatic breast cancer (MBC) are associated with clinical resistance to endocrine therapy. A highly sensitive digital PCR (dPCR) assay was developed to evaluate the baseline abundance and kinetics of hotspot ESR1 mutations in plasma circulating tumor DNA (ctDNA) from 58 ER+ MBC patients who had progressed on at least one line of prior endocrine therapy. Consistent with prior reports, we demonstrate that detection of hotspot ESR1 mutations in plasma ctDNA is associated with shorter progression-free survival. However, after patients initiated a new course of systemic therapy, changes in plasma ESR1 mutation abundance did not correlate with the duration of disease control.

To investigate whether mutational heterogeneity may account for this lack of correlation, we developed a customized dPCR multiplexed amplicon next-generation sequencing (NGS) assay to detect plasma ctDNA mutations in the complete coding sequence of ESR1 and TP53, as well as hotspot regions in PIK3CA. Assay validation revealed a 79% sensitivity and 100% specificity for detecting plasma ctDNA mutations with a lower limit of detecting a 1.6% mutant allele fraction. The NGS assay revealed non-hotspot ESR1 mutations in plasma DNA from 14 of 31 (45%) patients. We also observed dynamic changes in plasma ctDNA mutant allele fraction of PIK3CA and TP53 during systemic therapy. Changes in the cumulative mutant allele fraction of ESR1, PIK3CA, and TP53 in plasma ctDNA correlated with duration of clinical treatment response in a limited subset of patients (n=8) for whom NGS was performed at two or more time points. Thus, mutational heterogeneity limits the clinical utility of monitoring individual hotspot mutations in ESR1 over time in ER+ MBC patients. However, a plasma ctDNA NGS assay targeting ESR1, PIK3CA, and TP53 may be useful as an early predictor of response to systemic therapy.
Biomarkers associated with resistance or response to CDK4/6 treatment in patients with metastatic hormone-receptive positive breast cancer

Janice N Mullins¹, Amina Chaudhry¹, Julie Ryder¹, Poojitha Valasareddy¹, Amit Jain¹, Harsha Ranganath¹, Felicia Hare¹ and Gregory A Vidal¹. ¹University of Tennessee Health Science Center / West Cancer Center, Germantown, TN.

Background:
CDK4/6 inhibitor (CDKi) drugs are the current standard of care for treatment of first and second-line hormone-receptor positive/HER2 negative (HR+/HER2-) metastatic breast cancers. Numerous research efforts have commenced to understand biomarkers of response and resistance. To date, no biomarker of response has been identified. Treatment induced RB1 mutations were noted as mechanism of resistance to palbociclib and fulvestrant in about 5% of patients treated on PALOMA3 trials, whereas PI3K and ESR1 mutations emerged as potential resistance to the anti-hormonal backbone¹. Additionally, FGFR1 amplification has been suggested as a resistance pathway to fulvestrant and ribociclib². A better understanding of the molecular landscape of CDK4/6 treatment is needed. Utilizing next-gen sequencing (NGS), chromogenic in situ hybridization (CISH) and immunohistochemistry (IHC) data from HR+/HER2- patients treated at the University of Tennessee West Cancer Center, we attempted to retrospectively identify a molecular signature of resistance or response as measured by PFS.

Methods:
We analyzed 115 breast cancer patients who received CDKi treatment and 30 matched controls not exposed to CDKi and underwent comprehensive molecular profiling (Caris Life Sciences, Phoenix, AZ). A Cox proportional hazards model was built using genetic test as predictors and progression free survival (PFS) time as response. Only alterations with known pathogenic potential were considered aberrant. The R package glmnet was used to perform regularized lasso regression for feature selection on the entire data set. Important features were then used to construct Kaplan-Meier curves and perform a log-rank test for difference in PFS times.

Results:
Here we report the analysis for 2 known pathogenic biomarkers, ESR1 and TP53 based on PFS for patients who test positive versus negative. The median PFS for all patients was 234 days. Patients who harbored ESR1 mutations had reduced PFS of 180 days compared to 237 days. Patients who had P53 mutations had shorter PFS of 201 days compared to 240 days. When both groups with positive mutations were combined, the median PFS was 191 days compared to 276 days for patients without either ESR1 or P53 mutation with a p-value of 0.011. Further analysis using 4 way Kaplan Meier Curves for controls versus treated, altered versus non-altered genes, or PDL-1 expression is ongoing and will be presented at the conference.

Conclusion:
This data further support, in a real world model, the poor predictive value of ESR1 and P53 mutations on clinical outcome. Because no testing data was used, additional validation will be necessary to confirm the findings from this analysis.

A preliminary assessment of knowledge, attitudes, and awareness surrounding ESR1 mutations and biomarker testing amongst medical oncologists

Shari B Goldfarb¹, Matthew P Goetz², Paul P Plourde³, Elizabeth Attias³ and David J Portman³. ¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Mayo Clinic, Rochester, MN and ³Sermonix Pharmaceuticals, Columbus, OH.

**Background:** Estrogen receptor gene (ESR1) mutations present in breast cancer patients are associated with resistance to endocrine therapy and worse patient outcomes. Recent findings suggest ESR1 mutations are present in up to 40% of metastatic breast cancer (mBC) patients' tumors. The objective of this study was to evaluate the perceptions of precision medicine and biomarker testing specific to ESR1 mutations among medical oncologists.

**Methods:** Ten 60-minute web-assisted, telephone interviews were conducted with medical oncologists. Each physician was prescreened prior to being interviewed to ensure board certification and practice experience between 2 and 35 years. Each participant spent greater than 30% of their time on direct patient care and managed the treatment of more than 30 different cancer patients per month, with a minimum of 15 breast cancer patients, including at least five who had metastatic breast cancer and at least one patient with an ESR1 mutation.

**Results:** A 10-20% prevalence of ESR1 mutation was estimated by the oncologists. However, the practitioners did accept the possibility of a 40% prevalence. Physician knowledge of ESR1 mutations included the relationship between ESR1 mutations and efficacy of endocrine therapies and its association with poorer outcomes. None of the medical oncologists interviewed were highly satisfied with the existing armamentarium of treatments for patients with an ESR1 mutation. In general, the interview participants were highly comfortable ordering ESR1 companion diagnostics to test for an ESR1 mutation, pending viable treatment options are available. Nonetheless, most physicians will wait until the patient has progression of disease before ordering a biomarker test. Several areas of unmet need in the mBC arena were offered by the survey participants, including more efficacious hormonal options for later-line therapies, better durability of remission, improved drug tolerability profiles, and lower treatment costs.

**Conclusion:** Most oncologists acknowledged that personalized treatment is beneficial because it allows for better efficacy than a “one size fits all” approach. The study results also suggest that there are few barriers and drawbacks to the use of personalized medicine in the mBC arena, as most physicians expect precision medicine to account for the majority of advances in breast cancer treatments in the foreseeable future.

Longitudinal changes in volumetric breast density and fibroglandular volume with endocrine therapy in African American women with estrogen receptor positive breast cancer

Helen M Johnson¹, Hitesh Shivalingappa¹, Jan H Wong¹, Mahvish Muzaffar¹, Kathryn Verbanac¹ and Nasreen A Vohra¹. ¹East Carolina University Brody School of Medicine, Greenville, NC.

Background and Aim:
Reduction in breast density has been proposed as a biomarker of response to endocrine therapy (ET). The vast majority of current data are derived from white or Asian women. Because baseline breast density is associated with race, it is possible that changes in breast density with treatment may also be affected by race. Our objective was to assess the impact of ET on volumetric breast density (VBD) and fibroglandular volume (FGV) in African American (AA) women with invasive breast cancer.

Methods:
We conducted a retrospective study of AA women diagnosed with estrogen receptor positive invasive breast cancer at our institution from 2009-2013. Mammograms within two years prior to diagnosis and at least 6 months post-diagnosis were utilized for comparing density measurements. Using Volpara automated software, VBD and FGV were measured for the contralateral normal breast by averaging the respective values measured on the craniocaudal and mediolateral oblique views.

Results:
51 women met the inclusion criteria and were confirmed to have received ET. Sixteen women received tamoxifen, 34 received an aromatase inhibitor, and medication data was unavailable in one case. The mean age at diagnosis was 56 years (range 29-72, median 55). 53% of women had stage I disease, 29% had stage II disease, and 18% had stage III disease. The majority of women had ER+ PR+ HER2 - disease (82.4%). 53.0% of women received systemic chemotherapy and all but one woman were treated surgically. Average body mass index (BMI) at diagnosis was 36.5, with data not available for 22 women. The mean time between diagnosis and baseline mammogram was 32 days, and the mean time between follow-up mammogram and baseline mammogram was 401 days. Average BMI at one year follow up was 33.7, with data not available for 19 women. The mean baseline VBD was 7.5% (range 1.9-21.5%, median 6.3%) and the mean follow-up VBD was 6.9% (range 2.0-23.6%, median 5.6%). Fifteen women had a longitudinal increase in VBD. The mean absolute change in VBD was -0.6% (range -3.4% to +9.8%, median 0.7%), with a mean 8.0 percent decrease from baseline to follow-up (range -0.7 to +0.5, median 0.1). The mean baseline FGV was 72.3 cm³ (range 18.5-208.4, median 65.3) and the mean follow-up FGV was 69.7 cm³ (range 22.7-197.5, median 60.5). Nineteen women had a longitudinal increase in FGV. The mean absolute reduction in FGV was 2.6 cm³ (range -53.3 to 49.3, median 4.8), with a mean 0.9 percent decrease from baseline to follow-up (range -111.6 to +53.0, median 5.2).

Conclusions:
We observed an overall decrease in Volpara-calculated VBD and FGV in our cohort of AA women treated with ET. It remains to be determined whether changes in VBD and FGV across serial mammograms may be a biomarker for response to ET in women of all races. Large prospective studies are needed to evaluate the effects of ET on longitudinal changes in VBD and FGV while controlling for confounders such as menopausal status, BMI, and chemotherapy.
A novel gene expression signature prognostic for both locoregional and distant failure and predictive for adjuvant radiotherapy

Martin Sjöström¹, S Laura Chang², Nick Fishbane³, Elai Davicioni³, Shuang G Zhao⁴, Linda Hartman¹, Erik Holmberg⁵, Felix Y Feng⁶, Corey W Speers⁴, Lori J Pierce⁴, Per Malmström¹, Mårten Fernö¹ and Per Karlsson⁵. ¹Lund University, Clinical Sciences Lund, Oncology and Pathology, Lund, Sweden; ²PFS Genomics, Vancouver, Canada; ³GenomeDx Biosciences, Vancouver, Canada; ⁴University of Michigan, Michigan, MI; ⁵Gothenburg University, Sahlgrenska Academy, Gothenburg, Sweden and ⁶University of California, San Francisco, San Francisco, CA.

**Background:** Most patients with early stage breast cancer (BC) are treated with adjuvant radiotherapy (RT) following breast conserving surgery (BCS) to prevent locoregional recurrences (LRR). No predictive tools are currently available to select patients for RT, resulting in considerable over- and under treatment. We aimed to create and validate a gene expression-based classifier to prognosticate for LRR and to stratify patients for treatment with RT.

**Patients and methods:** A 27-gene expression signature was developed using three publicly available early stage BC gene expression datasets where patients were treated with RT and had detailed local recurrence information. The largest of the datasets was used to train the signature, and the other two datasets were used for signature refinement. As age was the strongest clinical factor for the endpoint in the training dataset, it was included in the model, resulting in a final clinical-genomic classifier of 27 genes and age. The classifier was locked before external validation in the SweBCG91-RT trial. This phase III clinical trial included primary tumors from 765 patients and for which gene expression data was available. The trial randomized node-negative BC patients to +/- RT following BCS, with sparse use of adjuvant systemic treatment (9%) and a median follow-up of 14.0 years for LRR in patients free from event. The classifier was validated using Cox regression with LRR as the primary endpoint, and hazard ratios (HRs) were calculated using the raw continuous classifier score (range: 0.5 to 2.5).

**Results:** The novel classifier was highly prognostic for LRR in SweBCG91-RT patients treated with RT (HR=7.5[3.3-16.9], p<0.001), and remained prognostic in multivariate analysis (MVA) that included systemic treatment, subtype and grade (HR=7.2[3.1-16.4], p<0.001). To a lesser extent, the classifier was also prognostic for LRR in patients not treated with RT (HR=1.9[1.0-3.5], p=0.03; MVA HR=1.9[1.0-3.3], p=0.05). Patients at high risk of LRR had a smaller effect of RT, and the treatment predictive potential was confirmed by testing for interaction (p interaction=0.008). In patients treated with RT, age and the genomic component of the model were both prognostic for LRR (p<0.01) as well as predictive for RT response (p interaction<0.05) and provided independent information (p<0.01). The combined classifier has increased performance over its individual components (10-year AUC=0.72, 0.67, 0.65 for the classifier, age, and genomic component, respectively). While the novel signature was prognostic for metastasis (HR=4.3[2.3-7.8], p<0.0001), calculated scores from previously published signatures to the metastasis endpoint, including the Oncotype-like score, were not prognostic for LRR.

**Conclusions:** This novel gene expression signature is highly prognostic for LRR, can identify patients at risk of LRR despite RT, and appears to be treatment predictive for adjuvant RT. Furthermore, the current signature is highly prognostic for metastasis. In contrast, calculated scores of previously published signatures modeled for the metastasis endpoint had inferior performance for LRR. These results underscore both the importance of signatures prognostic for LRR and the similarities in the biology of LRR and distant failure.
PTEN alterations and tumor mutational burden (TMB) as potential predictors of resistance or response to immune checkpoint inhibitors (ICI) in metastatic triple-negative breast cancer (mTNBC)

Romualdo Barroso-Sousa¹,², Svitlana Tyekucheva³, Sonia Pernas-Simon¹,², Pedro Exman¹,², Esha Jain⁴, Ana C Garrido-Castro¹,², Melissa Hughes¹, Brittany Bychkovsky¹,², Simona Di Lascio⁶, Renato Umelon⁵, Janet Files⁵, Neal I Lindeman⁵,⁷, Laura E MacConaill⁵,⁷, F Stephen Hodi¹,², Ian E Krop¹,², Deborah Dillon⁴, Eric P Winer¹,², Nancy U Lin¹,², Elizabeth A Mittendorf¹ and Sara M Tolaney¹,². ¹Dana-Farber Cancer Institute, Boston, MA; ²Harvard Medical School, Boston, MA; ³Harvard T.H. Chan School of Public Health, Boston, MA; ⁴Broad Institute of MIT and Harvard, Cambridge, MA; ⁵Brigham and Women’s Hospital, Boston, MA; ⁶Oncology Institute of Southern Switzerland, Bellinzona, Switzerland and ⁷Center for Cancer Genome Discovery, Dana-Farber Cancer Institute, Boston.

Purpose: To date no biomarker has been identified that predicts response to ICI in mTNBC. This study aimed to explore if tumor genomic alterations correlate with efficacy of PD-1/PD-L1 inhibition in patients (pts) with mTNBC. Methods: Demographic, treatment response, and long-term outcome data were collected on patients with mTNBC treated at Dana-Farber Cancer Institute (DFCI) under several clinical trials incorporating PD-1/PD-L1 inhibitors, given as monotherapy or combined with chemotherapy (CT). Pts included in this analysis had available results of targeted exon sequencing performed using Oncopanel, our institutional gene sequencing panel, on archival tumor tissue. TMB was calculated by determining the number of non-synonymous somatic mutations that occur per megabase of exonic sequence data across all genes on the panel. High TMB was defined as ≥10 mutations/megabase. TMB and gene alterations were correlated with objective response rate (ORR) per RECIST 1.1, progression-free (PFS) and overall survival (OS). Results: A total of 50 pts with mTNBC were included in this analysis. At baseline, the median age was 55.9 years (31.8–75.9), 60% had ECOG 0 and 40% had ECOG 1, 72% had visceral metastasis, and 46% had received ≥1 prior lines of systemic therapy in the metastatic setting. While 26% of pts received monotherapy [pembrolizumab (n=7; NCT02447003); atezolizumab (n=6; NCT01375842)], 74% received combination with CT [pembrolizumab plus eribulin (n=31; NCT02513472); atezolizumab plus nab-paclitaxel (n=6; NCT01633970)]. PTEN alterations were present in 30% of pts (mutations = 7; one copy number loss = 7; two copy number loss = 1). Median follow-up was 14 months (1–40). Pts with tumors harboring PTEN alterations had lower ORR (7% vs 57%; P<0.001), shorter median PFS (2.3 vs 6.3 months; P=0.027), and shorter median OS (8.1 vs 20.1 months; P=0.012) compared to pts without PTEN alterations. The median TMB was 6.6 mut/Mb (1.2–50.8), and 23% of pts had a high TMB. While high TMB was not associated with higher ORR (P=0.56), it was associated with better median PFS (16.5 vs 2.4 months; P=0.017), and better median OS (not reached vs 13.5 months; P=0.026). Both PTEN status and TMB remained significantly associated with PFS in the multivariable model.

Only PTEN status remained significantly associated with OS in the multivariable analysis with the same covariables. Ongoing analysis to better understand if these predictors are specific for predicting benefit to immunotherapy and/or a marker of chemotherapy resistance will be presented at the symposium. Conclusion: PTEN genomic alterations and TMB may impact benefit from PD-1/PD-L1 inhibitors largely administered with chemotherapy in mTNBC. These observations warrant prospective
validation and may inform the importance of stratifying pts according to these characteristics in future randomized studies with ICI.
Genome copy number entropy as predictor of response for neoadjuvant therapy in early breast cancer

Background
Copy Number Alterations (CNAs) represent changes in the copy number of genomic segments of somatic cells due to chromosomal instability. CNAs include gene amplifications or deletions and can be involved in tumorigenesis. We analyzed CNAs data in pre- and post-treatment (ttm) tumors from patients (pts) with early breast cancer (BC) in the neoadjuvant trials GEICAM/2006-03 and GEICAM/2006-14, with the aim to identify CNAs in particular genomic regions (genetic entropy) associated with treatment response.

Methods
GEICAM/2006-03 (NCT00432172) HER2-negative pts were selectively treated according to clinical subtypes: triple negative (TN) pts were treated with standard anthracycline/taxane -based chemotherapy (AT-CT) +/- carboplatin, while luminal patients were randomized to AT-CT vs. hormonotherapy; GEICAM/2006-14 (NCT00841828) HER2+ pts received AT-CT plus anti-HER2 therapy. Shallow-whole genome Illumina sequencing DNA data from 204 paraffin-embedded tumors (100 pre- and 104 post-ttm) were segmented to obtain CNAs and recurrent altered genomic regions were defined. We used Wilcoxon test to analyze the frequency of altered regions and logistic regression analyses to explore their association with tumor response, in terms of pathological complete response (pCR) in breast and axilla. Validation of altered genes associated with therapy response was performed in the microarray gene expression-based Hatzis dataset (GSE25066) from pts receiving neoadjuvant AT-CT (1).

Results
A total of 672 regions covering the whole genome were identified upon analysis of CNAs data. Regions were categorized according to their alteration status as amplified, normal and lost. Comparative analysis of alterations revealed 11 regions significantly different (p<0.05) in pre- vs post-ttm tumors. Logistic regression analysis showed that in pre-ttm tumors specific alterations of 8 regions localized in 3 different genomic loci (11q12, 16q22 and 21q22) were significantly associated with pCR (p<0.05). Independent analyses of CNAs data with “CGH regions” and “GISTIC2.0” tools confirmed the special relevance of 2 of these 8 regions (#653 and #654), amplified in the locus 21q22.12. This locus contains 20 genes whose expression was tested in Hatzis dataset (1) (GSE25066): the analysis showed that overexpression of 5 of these 20 genes (CHAF1B, CBR1, CBR3, RCAN1 and SLC5A3) turned out to be significantly higher in the cohort of pts who reached pCR, in agreement with our findings. Some of these genes have already been described as proliferation markers (CHAF1B) or involved in treatment response (CBR1) in BC. Other genes related to BC in this genomic region are the transcription factor RUNX1 and the Lysine Methyltransferase SETD4.

Conclusions
According to our results, neoadjuvant therapy can modulate genomic aberrations landscape in BC. Our data suggest that amplification of specific genes in the genomic locus (21q22.12) is involved in the neoadjuvant therapy response in early BC. (1): Hatzis et al., JAMA 2011, 305(18) 1873-81
A new method of data analysis to derive DNA methylation signatures that stratify risk of recurrence in triple negative breast cancer

Bradley M Downs¹, Leslie M Cope¹, Mary Jo Fackler¹, Soonweng Cho¹, Antonio C Wolff¹, Meredith M Regan², Saraswati Sukumar¹ and Christopher B Umbricht¹. ¹Johns Hopkins University School of Medicine, Baltimore, MD and ²IBCSG Statistical Center, Dana-Farber Cancer Institute, Boston, MA.

Background: Triple negative breast cancer (TNBC) accounts for 10-17% of all breast cancer and is more likely to be of higher histological grade, poorly differentiated, associated with a higher recurrence rate and with decreased overall survival. The clinical course of a TNBC patient remains difficult to predict, as tumors with homogenous morphological characteristics may vary in response to therapy and have divergent outcomes. Therefore, additional analytical methods are needed to better classify TNBC. Our goal is to refine the analysis of methylome datasets to derive reliable molecular signatures that can distinguish TNBC patients with good outcomes who may benefit from less aggressive treatment, from those with poor outcomes who would be candidates for more aggressive treatments.

Methods: Our laboratory has conducted and reported, in this meeting, results from analysis of 450k methylation array data on a discovery set of 53 high-risk TNBC cases and 62 low-risk controls treated by locoregional therapy alone, as well as 5 normal breast tissue samples. High-risk cases were defined as patients that relapsed within 0.5 to 6.5 years from the time of diagnosis, while low-risk controls had no relapse and >4 year recurrence-free intervals (RFI). In this work, we devised and applied a novel methylation biomarker discovery program named Hypermethylated Outlier Detector (HOD) that emphasizes the selection of highly methylated markers in cases compared to controls, to find a high-risk signature in the TNBC discovery set. The methylation signature identified by HOD was interrogated in a test set of 50 TNBCs (with 16 recurrences) that did not receive chemotherapy, and in a second test set of 131 TNBCs (with 33 recurrences) that did receive chemotherapy.

Results: HOD identified 39 hypermethylated markers (beta >0.20) that could accurately distinguish between the high-risk cases and the low-risk controls in the discovery set of TNBCs (n=115) treated with locoregional therapy alone. In the test set of TNBC (n=50) with no chemotherapy the 39 markers distinguished high from low risk individuals (likelihood ratio test P=0.049). In a second test set of TNBC (n=131) that received chemotherapy the 39 hypermethylated markers again distinguished high from low risk individuals (likelihood ratio test P=0.0043).

Conclusions: We have presented evidence that a methylation signature identified by HOD can be used to identify TNBC patients that have a high-risk of relapse regardless of receiving chemotherapy. This methylation signature could potentially be used to inform physician decisions on therapeutic strategies for TNBC patients. This could ultimately lead to less aggressive treatment given to patients possessing a methylation profile consistent with a better prognosis. Conversely, patients with hypermethylation in the 39 markers will likely benefit from a more aggressive course of treatment.
Phenotypic discordance between primary and metastatic breast cancer (MBC) in a large scale real-life multicentre French cohort

Sarah Lefevre¹, Amélie Lusque², Natacha Joyon³, Laurent Arnould⁴, Frédérique Penault-Llorca⁵, Gaëtan MacGrogan⁶, Isabelle Treilleux⁷, Anne Vincent-Salomon⁸, Juliette Haudebourg⁹, Aurélie Maran-Gonzalez¹⁰, Emmanuelle Charafe-Jauffret¹¹, Coralie Courtinard¹², Camille Franchet², Véronique Verriele¹³, Etienne Brain¹⁴, Patrick Tas¹⁵, Suzette Delaloge¹, Thomas Filleron² and Magali LaCroix-Triki¹. ¹Gustave Roussy, Villejuif, France; ²Institut Claudius Regaud, IUCT-Oncopôle, Toulouse, France; ³APHP - Hôpital Cochin - Service d'Anatomie et Cytologie Pathologiques, Paris, France; ⁴Centre GF Leclerc, Dijon, France; ⁵Centre Jean-Perrin, Clermont Ferrand, France; ⁶Institut Bergonié, Bordeaux, France; ⁷Centre Léon Bérard, Lyon, France; ⁸Institut Curie, Paris, France; ⁹Centre Lacassagne, Nice, France; ¹⁰ICM, Montpellier, France; ¹¹Institut Paoli-Calmettes, Marseille, France; ¹²Unicancer R&D, Paris, France; ¹³Institut de Cancérologie de l'Ouest, Angers, France; ¹⁴Institut Curie, Saint-Cloud, France and ¹⁵Atalante Pathologie, Rennes, France.

Background: Therapeutic options at diagnosis for metastatic breast cancers (MBC) differ largely according to cancer phenotype (namely, hormone receptor (HR) and HER2 status). Reported discordance rates between primary tumor and metastasis vary widely in literature, with a median of 18% for estrogen receptor, 31% for progesterone receptor and 10% for HER2. The present study aimed to compare phenotypic profiles between primary and MBC in the real-life setting.

Patients (pts) and methods: Epidemio-Strategy and Medical Economics (ESME)MBC data platform (NCT03275311) is a French national, multicenter, observational cohort using clinical trials' methodology for data capture, monitoring and quality controls. At the time of analysis, it comprised data of 16703 consecutive newly diagnosed MBC pts (1/01/08-31/12/14) treated in 18 French comprehensive cancer centres. The primary endpoint was the discordance rate of HR and HER2 status between primary tumor and MBC (biopsy of metastatic site done within 6 months of MBC diagnosis). Only patients with both histological reports available were considered. Potential factors associated with phenotype discordance were assessed in a multivariate logistic regression.

Results: 2933 out of 16703 (17.6%) had a biopsy in the first 6 months of metastatic disease. HR and/or HER2 status was available in 1677 pts.

*CNS= central nervous system, CSF=cerebro-spinal fluid

The discordance rate between primary and matched MBC was 14.2% (222/1566) for HR: loss of expression in 72.5%, gain in 27.5%. For HER2, the discordance rate was 7.8% (84/1076): 45.2% of losses and 54.8% of gains of expression. The primary HR+/HER2+ subgroup had the highest rate of changes: 53% (49/92) with either a loss of HR (43%), loss of HER2 (43%) or a loss of both (14%). 18% (33/181) of primary triple-negative breast cancer (TNBC) had a phenotypic change with a majority of HR gain (79%). In multivariate analysis, administration of adjuvant chemotherapy +/- targeted therapy was the sole independent predictor of HR status modification (OR: 1.73, 95%CI 1.27-2.36, p=0.001). The presence of a mixed histology was the only predictor of HER2 discordance (OR =2.57, 95%CI 1.19-5.55, p=0.016).

**Conclusion:** Biopsy and phenotype re-evaluation of MBC early in the disease course has a confirmed potential significant therapeutic impact in this large scale real life setting and should be proposed as often as possible.
Nuclear p-ser394-FOXO3a/FOXO3a ratio is associated with an improved survival and response to therapy in breast cancer

Ming Feng Hou, Hong Ying Dai, Luang You Yan, Sheau Fang Yang, Fang Ming Chen and Yao Tsung Yeh. ¹College of Medicine, Kaohsiung Medical University, and Kaohsiung Municipal Hsiao Kang Hospital, Kaohsiung City, Taiwan; ²Cancer Center, Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan; ³Institute of Biomedical Science, National Sun Yat-Sen University, Kaohsiung City, Taiwan; ⁴Graduate Institute of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan; ⁵Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung City, Taiwan; ⁶Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan; ⁷Aging and Disease Prevention Research Center, Fooyin University, Kaohsiung City, Taiwan and ⁸Fooyin University, Kaohsiung City, Taiwan.

Background: Forkhead box O (FOXO) transcription factors, one of large forkhead family members, control a wide spectrum of carcinogenesis, therapy response and progression in human cancer. Phosphorylation of FOXO3a by ERK1/2 at ser294, ser344, and ser425 induces its nuclear exclusion and sequestration in the cytosol, therefore avoiding FOXO3a transcriptional activity and consequently promoting cell proliferation and tumorigenesis. We aimed to explore the prognostic significance of subcellular p-ser294-FOXO3a distribution patterns in breast cancer.

Methods: Immunohistochemistry was used to explore expression patterns of ERK1/2, FOXO3a and p-Ser294-FOXO3a in 216 breast cancer lesions. The obtained information was statistically correlated with clinicopathological parameters including tumor size, lymph node metastasis, tumor stage, histological grade, estrogen receptor α (ER), progesterone receptor (PR), HER2 and patients' follow-up data. The median follow-up period was 118 months. Kaplan-Meier survival curves were analyzed using with log-rank test and Cox-regression model was used to determine their independent prognosis values.

Results: Our results showed that nuclear FOXO3a and p-ser394-FOXO3a expression were progressively increased from normal, early to advanced breast tumor. Nuclear p-ser394-FOXO3a and FOXO3a expression was positively correlated (p=0.021). Nerveless, cytoplasmic ERK expression was inversely correlated with nuclear FOXO3a expression (p=0.037), but not its phosphorylation at the ser394 residue. To determine the real impact of p-ser394-FOXO3a, we redefined the ratio of p-ser394-FOXO3a over FOXO3a as p-FOXO3a index. Using χ² analysis, we found nuclear p-FOXO3a index in tumor tissue was positively associated with lymph node metastasis (p=0.035) and inversely correlated with recurrence rate (p=0.035) in breast cancer patients. The Kaplan-Meier survival curve showed that nuclear p-FOXO3a index, but not cytoplasmic p-FOXO3a index, improved the overall survival rate (p=0.037). In addition, those patients who received hormone therapy would have a better survival rate when they had high nuclear p-FOXO3a index (p=0.005), suggesting that nuclear p-ser394-FOXO3a expression might be required for the response of hormone therapy. Intriguingly, low nuclear p-FOXO3a index significantly associated with the worse overall survival rate of patients who didn’t receive chemotherapy or radiotherapy (p=0.049 and p=0.049, respectively), implicating that nuclear p-ser394-FOXO3a expression might also modulate the response of chemotherapy and radiotherapy. Multivariate Cox regression analysis demonstrated that the nuclear p-FOXO3a index (HR=0.46, 95% CI=0.22-0.97, p=0.040), stage (HR=2.48, 95% CI=1.04-5.96, p=0.041), and recurrence (HR=5.69, 95% CI=2.69-12.04, p<0.001) were independent prognostic factors for the overall survival rate of breast cancer patients.

Conclusions: In conclusion, this study highlights that the phosphorylation of FOXO3a at the ser394 residue may play a crucial role in treatment response of breast cancer. Increased p-FOXO3a index may serve as a prognostic factor for an improved survival rate of breast cancer patients.
Expression of adipocyte fatty acid binding protein promotes obesity-associated mammary tumor growth

Edward Sauter², Jiaqing Hao¹, Xiaofang Yan¹, Maiying Kong¹ and Bing Li¹. 'Universtiy of Louisville, Louisville and ²University of Connecticut, Farmington.

Background: The underlying mechanisms that drive obesity-related breast cancer remain unclear. Adipocyte/macrophage fatty acid binding protein (A-FABP) is linked to obesity and breast cancer, while transforming growth factor (TGF)β appears to play a pleiotropic role in breast cancer, suppressing its development but promoting its progression. Whether the proteins work together to drive breast cancer progression is not known. We evaluated the expression of these two markers in matched serum from healthy women and women with breast cancer.

Hypothesis: A-FABP and TGFβ drive breast cancer development and progression.

Methods: Serum was collected under an institutional review board approved protocol. A-FABP was measured in serum collected from 275 women (92 with breast cancer and 183 without) and TGFβ from 245 matched women (92 with breast cancer and 153 without). A-FABP levels were measured using a human A-FABP4 ELISA kit while TGFβ was measured using human TGFβ ELISA kit. The Kruskal-Wallis test was used to determine if a difference in marker expression existed between women with and without breast cancer, as well as in women with early vs. more advanced breast cancer. Linear mixed effect models were used to examine the relationship between A-FABP and BMI, as well as between TGFβ and BMI, controlling for age, menopause status and a diagnosis of breast cancer.

Results: A-FABP expression was higher in obese than lean postmenopausal women, both those with breast cancer (mean: 44.9 vs. 25.1 ng/mL, p=0.002) and without breast cancer (39.4 vs. 26.9 ng/mL, p=0.003). A-FABP expression was also higher in premenopausal obese vs. lean women with cancer (28.9 vs. 12.7 ng/mL, p=0.027), but not in premenopausal healthy women. A-FABP expression was higher in postmenopausal obese vs. lean women with early stage (0-2A) breast cancer (45.6 vs. 21.9 ng/mL, p=0.013) and was inversely associated with HER-2 expression, though being of borderline significance (p=0.060). This was most notable among triple negative vs. ER/PR negative HER2 positive breast cancers. Considering both early and advanced breast cancer, TGFβ expression trended higher in post- than in pre-menopausal obese women with breast cancer (138.9 vs. 68.7 pg/mL, p=0.061), however among premenopausal women with advanced (Stages 2B-3C) disease, TGFβ expression was 5 fold higher in lean than obese individuals (251.7 vs. 48.2 pg/mL, p=0.029) but trended higher in obese vs lean postmenopausal women. TGFβ and A-FABP were found to be significantly associated (p=0.14, p=0.024).

Impact: Both A-FABP and TGFβ expression are associated with postmenopausal breast cancer among obese women, and their expression in matched samples is significantly associated.. TGFβ is associated with premenopausal advanced breast cancer in premenopausal women. TGFβ is known to induce epithelial mesenchymal transition and may play a role in pregnancy associated breast cancer. Further studies are needed to determine if A-FABP and TGFβ work together in postmenopausal breast cancer.
CD73 predicts response to neoadjuvant treatment in TNBC patients

Andrea Botticelli, Bruna Cerbelli, Annalinda Pisano, Giuseppe Naso, Massimo Monti, Paolo Antonio Ascierto, Leopoldo Costarelli, Valentina Magri, Maria Mauri, Maria Gemma Pignataro, Domenico Campagna, Angelina Pernazza, Marianna Nuti, Lucio Fortunato, Carlo Della Rocca, Giulia D'Amati and Paolo Marchetti. 1 Sapienza, University of Rome, Rome, Italy; 2 San Giovanni Addolorata, Hospital, Rome, Italy and 3 Istituto Nazionale Tumori -IRCCS- ’Fondazione G. Pascale’, Naples, Italy.

BACKGROUND Immune system plays a key role in tumor surveillance and escape. Tumor infiltrating lymphocytes (TILs) and PD-L1 seem to predict clinical outcome and pathological response (pR) after neoadjuvant chemotherapy (NAC) in breast cancer. Recently CD73 has been proposed as prognostic biomarker associated with better disease free survival and overall survival patients affected by triple negative breast cancer (TNBC). CD73 catalyzes the conversion of AMP in adenosine which leads to an immunosuppressive microenvironment. Indeed adenosine inhibits CD8+ lymphocytes and dendritic cells while enhances M2, myeloid suppressor cells and Treg activity.

MATERIALS AND METHODS
We enrolled 61 pts who had received NAC (EC for 4 cycles followed by Paclitaxel q7 for 12 cycles or q21 for 4 cycles) between January 2013 and June 2017 at Policlinico Umberto I and San Giovanni Addolorata Hospital of Rome. We performed immunohistochemistry for CD20, CD3, CD4, CD8, CD68, N-CAM, PD-L1 (Ventana SP142 clone) and CD-73 in basal paraffin-embedded biopsies. CD73 and PD-L1 expression on tumor cells was evaluated both qualitatively and quantitatively. The percentage of tumor-infiltrating immune cells positive for PD-L1 and CD73 was also recorded. Statistical analysis was performed with Mann Whitney test, univariate, and multivariate logistic regression models.

RESULTS
We enrolled 61 females (median age: 49 y; range 28-74) affected by TNBC: 59 ductal Ca G3 NST (96.7%), 1 mucinous carcinoma (1.6%), 1 medullary carcinoma (1.6%). The clinical stage before NAC was as follow: 13.1% cT1 (8 pts), 75.4% cT2 (46 pts), 4.9% cT3 (3 pts), 6.6% cT4 (4 pt). 32 pts were cN+ (52.5%). After NAC 29 patients underwent mastectomy (47.5%) and 32 conservative surgery (52.5%). Twenty-three patients (38%) showed pathological complete response (pCR). The median value of expression of CD73 on tumor cells was 40%. In 29 (48%) basal biopsies CD73 expression was under median value. Five out of 61 patients presented PD-L1 expression higher than 25%. Fourteen out of 29 (48%) patients with low level of CD73 expression achieved pathological complete response (pCR), on the contrary only 9 out of 32 (28%) of patients with high levels of CD73 showed pCR (p=0.011). Four patients (80%) with high PD-L1 expression achieved pCR (p=0.035). At multivariate analysis a significant association was found between pCR and CD73 expression (p =0.027) while no association was found with TILS and PD-L1.

CONCLUSION: CD73 expression seems to be associated with pCR in TNBC patients. Moreover these preliminary results suggest the possibility of using CD73 inhibitor plus anti-PD-1 in those patients with high expression of CD73.
The ≥5% cut-off reveals tumor PD-L1 positivity as potential selection biomarker for patient enrollment into the trials evaluating anti-PD-1 or anti-PD-L1 agents in neoadjuvant treatment of triple negative breast cancer

Wilfrid Finck¹, Judith Passildas¹, Camille Poirier¹, Fabrice Kwiatkowski², Catherine Abrial², Xavier Durando², Frederique Penault-Llorca² and Nina Radosevic-Robin². ¹Centre Jean Perrin, Clermont-Ferrand, France and ²UMR1240 INSERM/UCA, Centre Jean Perrin, Clermont-Ferrand, France.

Background: Durable responses of triple negative breast cancer (TNBC) to pembrolizumab (anti-PD-1) or atezolizumab (anti-PD-L1) have been reported in the metastatic setting. Moreover, it is currently being hypothesized that immune checkpoint inhibitors might be more effective in the neoadjuvant setting, due to better preserved anti-tumor immunity in early TN disease. However, biomarkers predictive of response to anti-PD-1 or anti-PD-L1 agents, as well as biomarker-based strategies for testing those drugs in the neoadjuvant setting are still lacking. We evaluated PD-L1 protein expression and the composition of tumor-infiltrating lymphocytes (TILs) in untreated TNBC, in order to get a better insight into the TNBC sub-population(s) which would be suitable for neoadjuvant anti-PD-1 or anti-PD-L1 therapy evaluation. Methods: TNBC patients consecutively treated at the Jean Perrin Comprehensive Cancer Centre (Clermont-Ferrand, France), from 01/01/2010 to 12/31/2014, were included. FFPE tumor tissues were assessed for PD-L1 expression by immunohistochemical (IHC) laboratory-developed test (clone 28-8, Abcam), in tumor cells (tPD-L1) and in TILs. Positivity cut-offs evaluated were ≥1%, ≥5% and ≥10%. The amount CD8+, CD4+, FoxP3+ or PD-1+ TILs was determined by counting those cells, detected by IHC methods, within 5 consecutive HPFs (x400), from tumor invasive front toward tumor center. Clinical disease stage was determined using the TNM system. Results: One hundred and two TNBCs were assessed. There were 28.4%, 23.5% or 16.7% tPD-L1-positive cases (cs), for cut-offs ≥1%, ≥5% or ≥10%, respectively. Similarly, 32.4%, 15.7% or 5.9% of cs were positive for PD-L1 in TILs, using the same cut-offs. With ≥5% as cut-off, positivity for tPD-L1 significantly correlated with the amount of CD8+ (p=0.023), FoxP3+ (p=0.0036) or PD-1+ TILs (p=0.043). The same cut-off, applied to TILs, revealed significant correlations between PD-L1 positivity and the amount of each CD8+, CD4+ or PD-1+ TILs (p=0.025, 0.039 and 0.0042, respectively). Interestingly, when the ≥5% cut-off was used, tumors of T2 size were most frequently tPD-L1+ (11/41 cs, 26.8%), compared with the T1 (3/35 cs, 8.6%) and T3+T4 (3/18 cases, 16.7%) (p=0.04). With regards to TILs, with the ≥5% cut-off, the PD-L1+ cases belonged exclusively to the T1+T2 group (15/76), whereas the T3+T4 group was PD-L1-negative (0/18 cs). Other two cut-offs revealed only occasional correlations. Conclusion: This single-center, real-world TNBC cohort contained a high number of smaller tumors (T1-T2). The IHC-based PD-L1 assessment, with ≥5% as the positivity cut-off, revealed that approximately 1/4 of TNBC could be candidates for neoadjuvant anti-PD-1/anti-PD-L1 approaches. Combined with the amount of CD8+ and PD-1+ TILs, tumor PD-L1 positivity might make an easy-to-use composite biomarker for the 1st-level patient selection for PD-1 or PD-L1 inhibitors in neoadjuvant TNBC treatment. The 2nd level could exploit, for example, the assessment of mutation burden in tumors with low tPD-L1 or amount of CD8+ or PD-1+ TILs. Such tumors might be more frequent among larger TNBC (T3-T4).
Circulating progranulin (GP88) level is associated with both response to therapy and progression of disease in metastatic breast cancer patients

Ginette Serrero¹, Douglas M Hawkins², David J Hicks¹, Nancy Tait³, Binbin Yue¹ and Katherine R Tkaczuk³. ¹A&G Pharmaceutical Inc., Columbia, MD; ²Marlene and Stewart Greenebaum Cancer Center, University of Maryland, Baltimore, MD and ³University of Minnesota, Minneapolis, MN.

Imaging is the method of choice for monitoring of disease response to therapy during and post-treatment in metastatic breast cancer (MBC) patients. However, imaging has limited sensitivity for real-time monitoring so clinicians use circulating tumor markers such as CA15-3, as surrogates for monitoring changes in disease, albeit with some limitations. Measuring tumor markers associated with the biologically driven tumor processes of development, proliferation and survival would add significantly to current disease information available and would improve the clinical management of this underserved patient population.

Biological studies demonstrated that the 88kDa glycoprotein Progranulin (GP88) is a critical driver of breast cancer (BC) cell proliferation, survival, invasiveness and drug resistance. GP88 is expressed in tumor tissue and not in normal breast tissue and is secreted in the circulation of BC patients. Studies demonstrated that high tumor GP88 expression is prognostic for recurrence and that BC patients had a statistically elevated GP88 serum level compared to healthy controls. We hypothesized that changes in serum GP88 levels correlate with changes in disease state as defined by RECIST 1.1. In this current study, we examined whether GP88 and CA15-3 serum levels were correlated to disease progression and response to therapy. Additionally, we compared the information provided by the GP88 /CA15-3 combination in disease progression or response to therapy.

101 stage 4 MBC patients undergoing Standard of Care therapy were consented and enrolled under an IRB approved protocol at the University of Maryland Greenebaum Comprehensive Cancer Center. Patient demographics together with clinical and disease characteristics were collected as part of the study. Blood samples were drawn from each patient at specific times at follow-up visits during and post-therapy and tested for GP88 using A&G's GP88 enzyme linked immunoassay. Samples were tested for CA15-3 at the University's laboratory. Disease status was monitored and assessed by RECIST1.1 criteria and such assessment entered into the database.

Statistical analyses were carried out using the serum GP88 and CA15-3 results to test each for association with contemporaneous RECIST assessment of disease progression (PD) or response (R). We determined that contemporaneous GP88 is significantly associated with PD (p 0.0101) and R (p 0.0194) while CA-15-3 is associated with PD (p <0.001) but not R (p 0.7316). Further, we used logistic regression to examine for additional information provided by each biomarker by modelling disease (PD or R) as dependent on the log-transformed GP88 and CA15-3 values. We determined that both GP88 and CA15-3 show significance for PD meaning biomarkers adds information while for R only GP88 had high significance meaning GP88 alone is significant and sufficient for R and CA15-3 does not add any value.

We conclude that circulating levels of GP88/PGRN in MBC patients are correlated with both disease progression and response to therapy and that monitoring circulating GP88/PGRN levels would be complementary to CA15-3 determination and imaging to provide valuable insight into real-time monitoring of the disease status of MBC patients.
M2 macrophages increase after neoadjuvant HER2 targeted chemotherapy

Purpose: Recent observations suggest a positive association between the presence of tumor-associated myeloid and lymphoid immune cells and clinical responses to HER2 therapies. The specific immune cell composition of HER2+ tumors and the effects of therapy on the tumor immune microenvironment remains poorly understood; limiting efforts to effectively direct immunomodulatory agents in HER2+ breast cancer. We sought to assess the feasibility of a multiplex immunofluorescence strategy to characterize the immune milieu of HER2+ tumors, pre and post treatment.

Methods: We conducted a feasibility study using the Perkin Elmer OPAL multiplex dye chemistry for immunofluorescence of tumor, myeloid, and lymphoid cells in pretreatment biopsy and surgical resection tissues of 11 patients who received neoadjuvant HER2 antibody with chemotherapy. Two panels of up to 6 antibodies were studied including a predominantly myeloid panel targeting CD80, CD68, CD163, CD206, PD-L1, and cytokeratin; and a 'lymphoid/proliferation' panel targeting FoxP3, cytokeratin, Granzyme B, CD4, CD8, and Ki67. For paired samples, analysis of pre/post differences were analyzed using two tailed, t-test. Results: 100% of the pre-treatment biopsy samples yielded high quality immune and tumor cell immunofluorescence profiles for both panels. In contrast, post treatment specimens were more challenging. For the post treatment tissues, ~25% of specimens failed to yield results in at least one panel. As shown in Table 1, the %CD206+ M2 type macrophage population increased between pre and post treatment (p=0.012). This was reflected in a decrease in the M1:M2 ratio and variability in the ratio in favor of M2 (median 0.34 [IQR = 1.01] to 0.11 [IQR=0.10], p=0.0003). In the lymphoid panel, we observed a non-significant reduction in % FoxP3+CD4 T cells with less variability between patients post treatment and a significant decrease in total CD8+ T cells. Further, there was a significant reduction in %Granzyme B positive T cells (median 6.63 to <1%, p=0.02) and non-significant decrease in proliferating (Ki67+) T cells post treatment. PD-L1 expression was low in both pre and post specimens.

Conclusions: Multiplex immune profiling is a practical approach to characterize the tumor immune microenvironment in biopsy and post treatment specimens. Neoadjuvant HER2 targeted chemotherapy significantly shifts the myeloid population to an M2 (immunosuppressive) phenotype with evidence for a reduction in the number of Ki67 and Granzyme B+ T cells. These preliminary
results suggest immunomodulatory agents that are able to induce or maintain an M1 polarized tumor microenvironment may have utility to enhance long term anti-tumor immunity in HER2 disease.
ROCplot.org: validating predictive biomarkers of response to chemotherapy/hormonal therapy/anti-HER2 therapy using transcriptomic data of 3,150 breast cancer patients

Balázs Győrffy1,2 and János Fekete1. 1Semmelweis University, Budapest, Hungary and 2MTA TTK, Budapest, Hungary.

Prognostic biomarkers are capable to predict survival and predictive biomarkers are capable to predict therapy response. Systemic therapy of breast cancer can include chemotherapy, hormonal therapy, and targeted therapy. Here, we report the initial release of the first online available tool capable to identify gene expression based predictive biomarkers using transcriptomic data of a large set of breast cancer patients.

Published gene expression data of 44 publicly available datasets was integrated with treatment data into a unified database. The classification is based on either author-reported pathological complete response (n=1,775) or relapse-free survival status at five years (n=1,329). Treatment data includes chemotherapy (n=2,108), endocrine therapy (n=971), and anti-HER2 therapy (n=267). The transcriptomic database includes 20,089 unique genes and 54,675 probe sets. Gene expression and therapy response are compared using receiver operating characteristics and Mann-Whitney tests.

We demonstrate the utility of the tool by validating a set of established biomarkers including TP53 for chemotherapy in luminal breast cancer (p=5.2e-20, AUC=0.77), ERBB2 for trastuzumab therapy (p=8.4e-04, AUC=0.629), and PGR for hormonal therapy (p=8.6e-05, AUC=0.7).

The tool is designed to validate and rank new predictive biomarker candidates in real time. By analyzing the selected genes in a large set of independent patients, one can select the most robust candidate and quickly eliminate those which are most likely to fail in a clinical setting. The analysis tool is accessible at www.rocplot.org/breast.
Changing level of serum heat shock protein 90 alpha as a diagnostic and predictive marker in breast cancer: Diagnosis of early breast cancer and prediction of response to neo-adjuvant and surgical therapy

Nanlin Hu¹, Mingzhou Li¹, Anjie Zhu¹, Feng Du¹ and Peng Yuan¹. ¹National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital,Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China.

To analyze the correlation of the level of serum heat shock protein 90α (HSP-90α) in healthy and breast cancer patients, studying the evaluation of neoadjuvant efficacy and Clinical value of relapse monitoring.

A total of 102 healthy women were selected, 51 cases of breast benign tumor, 423 cases of female breast cancer all diagnosed by pathology, other system malignancies 62 cases. ALL the serum samples HSP-90α was detected by double-antibody ELISA. The CEA, CA125, CA15-3 were detected by Roche Cobas ECL analyzer. The ROC curve was used to analyze the effectiveness of serum HSP-90α in the early diagnosis of breast cancer. The dynamic changes of HSP-90α level before and after treatment were analyzed by Wilcoxon's rank test. Moreover, we also combine the HSP-90α with CEA, CA125, CA15-3 to evaluate the clinical value of monitoring the recurrence of breast cancer.

The levels of serum HSP-90α (123.49 ± 105.1ng / ml) in breast cancer patients was significantly higher than that in healthy controls (40.33 ± 14.18ng / ml), benign breast disease (80.15 ± 103.09ng / ml) and carcinoma in situ (34.7 ± (114.31 ± 146.91ng / ml), the difference was statistically significant (P <0.001). According to the ROC curve analysis of patients and healthy subjects, the cut-off value was set as HSP-90α=59.7ng / ml, AUC=0.834, the sensitivity and specificity to diagnosis of breast cancer was 90.3% and 78.6% respectively, the negative predictive value was 93.88%. The levels of serum HSP-90α was significantly decreased (P <0.05) after tumor resection and the patients who obtain PR from the neoadjuvant chemotherapy. When HSP-90α=43.22ng / ml was set as the cut-off value for diagnosing the recurrence of breast cancer, AUC=0.877, the sensitivity and specificity were 95.7% and 74.5% respectively, and the negative predictive value was 96.2%. At the same time, we find that combined HSP-90α with CEA, CA125, CA15-3 can improve the accuracy of recurrence prediction.

Serum HSP-90α has a good clinical diagnostic value in breast cancer and can be used as a recurrence monitoring tool for post-adjuvant treatment patients.
A pilot study of metabolomics biomarkers in breast cancer tumors treated with neoadjuvant therapy

Pilar Zamora¹, Lucía Trilla-Fuertes², Andrea Zapater-Moros³, Angelo Gámez-Pozo², Guillermo Prado-Vázquez², María Ferrer-Gómez³, Mariana Díaz-Almirón⁴, Rocío López Vacas³, Enrique Espinosa¹ and Juan Angel Fresno Vara²,³. ¹Servicio de Oncología Médica. Hospital Universitario La Paz, Madrid, Spain; ²Biomedica Molecular Medicine SL, Madrid, Spain; ³Molecular Oncology & Pathology Lab, Institute of Medical and Molecular Genetics-INGEMM, La Paz University Hospital-IdiPAZ, Madrid, Spain and ⁴La Paz University Hospital-IdiPAZ, Madrid, Spain.

Introduction
Breast cancer is one of the most prevalent cancers in the world. Traditionally, early breast cancer treatment is based on surgery and, after surgery, hormone treatment or chemotherapy. However, the neoadjuvant treatment is increasingly used. Metabolomics is the most recent “omics” which allows quantify metabolites into blood patient samples. Coupled with computational analyses it could be possible to study differential metabolomics patterns and associate them with neoadjuvant response.

Material and methods
Blood plasma samples from patients with breast cancer treated with neoadjuvant chemotherapy were used to perform metabolomics experiments. One sample before the treatment (basal) and one sample after the chemotherapy (post-treatment) were analyzed and clinical data regarding response (complete response or partial response) was also collected. Metabolomics experiments were performed using liquid chromatography coupled with mass-spectrometry. Bayesian network and class comparison analyses were used to establish differential metabolic patterns between conditions. Additionally, a response prediction model based on logistic regression was build using metabolomics data from basal samples.

Results and discussion
A network showing the relationships between metabolites was build. Comparing metabolite measurements between complete response and partial response tumors in basal samples, 19 metabolites showed a differential quantification between both types of responses. Moreover, one of these metabolites is linoleic acid, previously described as a biomarker of complete response in neoadjuvant treatment in breast cancer. Using these 19 differential metabolites, a response predictive model was build. According to this model, it is possible to predict response to neoadjuvant treatment based on the amount of one metabolite, still only identified by its mass and charge. On the other hand, comparing basal and post-treatment samples, the network showed differential metabolomics patterns. These differential metabolites could be used as predictive biomarkers of response.

Conclusion
This study is a proof of concept that using a new “omics” technique such as metabolomics in blood samples, coupled with computational analyses, it is possible to identify differential metabolomics patterns between complete and partial response or basal and post-treatment samples and design predictive models of response. These results could facilitate in the future the implementation of blood-based tests into the clinical routine.
Hepatic-metastatiss pattern as a prognostic marker in metastatic breast cancer

Eun Kyo Joung¹, Ji-Hyun Yang² and Jieun Lee³. ¹Incheon St. Mary’s Hospital, Incheon, Republic of Korea; ²St.Mary’s Hospital, Seoul, Republic of Korea and ³Seoul St.Mary’s Hospital, Seoul, Republic of Korea.

Background: Liver is the third most frequent site for breast cancer metastasis. Despite of relatively high frequency of liver metastasis and its poor prognosis (median survival between 14-16 months), little is known about clinical outcome and histologic features or molecular mechanisms. The aim of this study was to identify the prognostic factor of breast cancer with liver metastasis, including the hepatic metastasis pattern by imaging studies and pathologic feature.

Methods: We reviewed medical record of breast cancer patients with hepatic metastasis diagnosed between January 2003 and June 2017. We classified spreading pattern of liver metastases detected by computed-tomography scan as following three types: mass-forming (longitudinal diameter of new hepatic lesion > 10mm, well-defined border for minimal 3 consecutive studies by CT scan), nodular (longitudinal diameter of any newly-noted hepatic lesion < 10mm or 10mm, well-defined border for minimal 3 consecutive studies by CT scan) and infiltration pattern (to spread with ill-defined border for minimal 3 consecutive studies by CT scan). The overall survival (OS) was defined as the period from the date of initial diagnosis of liver metastasis to the date of patient's death or last follow-up.

Results: 115 of patients with initially metastatic breast cancer, and 42 patients with recurrent breast cancer after curative surgery were enrolled. 13% of total patients presented with only liver metastasis when they are initially diagnosed as the metastatic breast cancer. 19% of total patients presented with nodular or infiltration pattern. Median OS of the patients with mass-forming liver metastasis was 18.1 (95% CI: 6.8-29.5) months and in nodular distribution and diffuse infiltration pattern was 13.4 (95% CI: 78-18.9) months (p=0.001). To elucidate the role of hepatic-metastasis pattern as a prognostic marker, we performed the cox-regression analysis. The patients with nodular/infiltrative liver metastasis showed poorer prognosis (hazard ratio: 2.18, 95% CI: 1.23-3.86, p-value: 0.007) than patients with mass-forming liver metastases significantly. Other prognostic marker is the subtype of breast cancer. Either HER2-positive (hazard ratio: 2.88, 95% CI: 1.59-5.23, p-value: 0.001) or triple negative breast cancer patients (hazard ratio: 6.17, 95% CI : 2.57-14.8, p-value<0.001) showed poorer prognosis than hormone-receptor positive subtype.

Conclusion: In the present study, the patients with mass-forming pattern of liver metastases hormone-receptor presentation showed favorable outcome in overall survival after liver metastases. Further studies are required for the different hepatic metastatic patterns and their mechanisms in metastatic breast cancer.
Combinatorial risk scores: Personalized multi-omic prediction of disease risk

Serdar Uckun\(^1\). PrecisionLife, Cambridge, MA.

Complex traits with heritable and lifestyle components present a challenge for traditional polygenic risk scores. These aggregate disease risk associations from multiple (tens to millions) low effect size SNVs to provide a quantitized group level risk. Typically this results in a binomial distribution of risk with the top and bottom percentiles having relatively clear clinical guidelines and a large number of intermediate patients for whom guidance is unclear.

From previous work on the genetic architecture of breast cancer (http://bit.ly/2JHLk8q) it is clear that particular combinations of multiple SNPs (epistatic interaction signatures) are significantly associated with specific levels of disease risk and disease protective effects. We have now extended identification of these signatures to include both genomic and phenotypic factors. We found:

- 3,045 novel risk signatures (combinations of 5-13 SNP variants) that occurred in large numbers of patients and zero controls
- 5 novel protective disease signatures (combinations of 2-10 SNPs associated with reduced disease risk)
- 10 genetically non-overlapping patient cohorts, each with a different disease risk
- Disease risk signatures that combine genetic and phenotypic factors, such as ethnicity, obesity, drinking and smoking

We have worked with UK Biobank, CIMBA and BCAC datasets to evaluate the risks/protective effects associated with each of these signatures. From these we are building combinatorial risk scores that better predict total lifetime disease risk, age of onset and therapy response. In the context of an individual patient, their specific SNVs and phenotype data can now be used to construct a personalized combinatorial risk score, which has the potential to enable both better diagnosis and theranostics. New results from these efforts will be presented at SABCS.

GWAS aim to find (single) genetic variant loci associated with specific phenotypes. While GWAS has been useful at identifying disease associated factors, it is known to provide only a limited model for explaining complex diseases as very few loci have significant effect sizes and most diseases are highly polygenic (Boyle, 2017). In addition, GWAS cannot directly include the impact of non-genomic factors such as phenotype, lifestyle and comorbidities that may modulate disease processes and exert significant influence over disease risks. Current detection methods for disease associated combinations of SNPs (epistatic interactions) are able only to find combinations of two or at most three SNPs from a preselected list. Here, we present an alternative to the single-locus limitations of GWAS

Penetrance for Clusters (sets of non-redundant states) validated using different FDRs for BRCA2 dataset

Analysis using a False Discovery Rate (FDR) of 5% identified 3,045 states (unique n-SNP combinations) at layers (order) 5 and 7–13 that were found to differentiate breast cancer susceptibility. The penetrance in the cohort depends on the FDR used as shown in Table.
Prognostic and predictive value of serum level of vascular endothelial growth factor-A in metastatic breast cancer patients treated with bevacizumab plus paclitaxel

Katsunori Tozuka¹, Shigenori E Nagai¹, Hiroshi Matsumoto¹, Yuji Hayashi¹, Kazuyuki Kubo¹, Miki Tsuboi¹, Ai Sato¹, Ken Takai¹, Xiaofei Wang¹, Yoko Yamada¹ and Kenichi Inoue¹. ¹Saitama Cancer Center, Ina, Kita-adachi-gun, Saitama-Ken, Japan.

Background
Several studies showed that first-line bevacizumab plus chemotherapy for HER2-negative metastatic breast cancer improves progression-free survival and tumor response rate but not overall survival. MERiDiAN trial evaluated plasma vascular endothelial growth factor-A (VEGF-A) prospectively as a predictive biomarker for bevacizumab efficacy in metastatic breast cancer. However, results of this trial do not support using baseline plasma VEGF-A to identify patients benefitting most from bevacizumab. We measured baseline serum VEGF-A level from stored blood samples of metastatic breast cancer patient with treated bevacizumab plus paclitaxel as first-line and later line therapy, and evaluated a correlation between serum VEGF-A level and efficacy of bevacizumab and prognosis of breast cancer patients treated with bevacizumab, retrospectively.

Patients and methods
We examined blood samples from 57 metastatic breast cancer patients treated with bevacizumab and paclitaxel, after obtaining written informed consent. And, we evaluated a correlation between baseline serum VEGF-A level and time to treatment failure (TTF) and overall survival (OS). We also compared the serum VEGF-A level of response group (CR and PR) and that of non-response group (SD and PD).

Results
Baseline serum level of VEGF-A ranged from 80 to 2079 pg/ml. Cases of treatment line were as follows: first-line, 22 cases (38.6%); second line, 11 cases (19.3%) and third-line and the later line, 24 cases (42.1%). The cutoff identified by ROC curve analysis that was able to differentiate response group and non-response group in first-line setting was 360pg/ml for serum VEGF-A. And, we separated high serum VGEF-A group and low serum VEGF-A group of patients treated with bevacizumab plus paclitaxel.

In patients treated as first line therapy, median TTF was 4.0 months with high serum VGEF-A group versus 5.0 months with low serum VEGF-A group, and median OS was 12 months with high serum VGEF-A group versus 11 months with low serum VEGF-A group. There were no significant differences in both TTF and OS in first line setting. In patients treated as second line and later line therapy, median TTF was 2.8 months with high serum VGEF-A group versus 7.1 months with low serum VEGF-A group, and median OS was 6.4 months with high serum VGEF-A group versus 12.7 months with low serum VEGF-A group. The prognosis of high serum VEGF-A group was significantly worse than that of low serum group in both TTF and OS.

The serum VEGF-A level of response group was tend to be higher than that of non-response group in first line setting, and was lower in second and later line setting. However, there were no significant differences.

Conclusion
In this study, serum VEGF-A cannot be a predictor for efficacy of bevacizumab plus paclitaxel as first line therapy for metastatic breast cancer patients. On the other hand, there was a possibility that high serum level of VEGF-A can be a poor prognostic factor in late line therapy setting of bevacizumab.
Two-year breast cancer survival in Sub-Saharan Africa: The multi-country ABC-DO cohort

Milena Foerster¹, Annelle Zietsman², Moses Galakunde³, Angelica Anele⁴, Charles Adisa⁵, Joachim Schuz¹, Isabel Dos Santos Silva⁶ and Valerie McCormack¹. ¹International Agency for Research on Cancer, Lyon, France; ²Windhoek Central Hospital, Windhoek, Namibia; ³Makerere University, Kampala, Uganda; ⁴Federal Medical Centre, Owerri, Nigeria; ⁵Abia State University Teaching Hospital, Aba, Nigeria and ⁶London School of Hygiene, London, United Kingdom.

Background: Breast cancer incidence in sub Saharan Africa is rising steeply and has recently replaced cervical cancer as the most common woman cancer in this region. Despite relatively low breast cancer incidence rates compared to those in the west, the 2012 GLOBOCAN estimates suggest mortality rates higher than those in the west, of 17.4 per 100,000 in all Africa and even up to 20.1 in Western Africa. However, breast cancer survival studies in the region are few, outdated, and often hampered by excessive losses to follow-up. Determinants of survival and progress over time are unmeasured.

Method: Using an innovative mHealth approach, the African Breast Cancer – Disparities in Outcomes (ABC-DO) cohort recruited over 2100 women newly diagnosed with breast cancer during 2014-17 in 5 Sub Saharan Africa countries. Women's complete breast cancer journeys are captured via three-monthly Smartphone based mHealth live data collection. Here we present the two year overall survival analysis for Namibia, Uganda and Nigeria.

Results: Breast cancer survival rates differ greatly between countries, but were generally low. After two years 129 of 501 women in Namibia, 160 of 429 women in Uganda and 177 of 395 women in Nigeria were deceased. Two-year year survival rates were 74%, 60% and 49% in Namibia, Uganda and Nigeria respectively. Stage at diagnosis had a strong influence on survival. The country adjusted preliminary hazard ratios compared to stage I and II were 3.1 (95% CI: 2.4; 4.0) for stage III and 8.4 (95% CI: 6.4; 11.2) for stage IV. Further, women from a higher compared to low socioeconomic position had lower mortality (preliminary HR: 0.55 (95% CI: 0.43; 0.70)).

Conclusion: Taking advantage of mobile technology, the ABC-DO study for the first time provides evidence based insight into the situation of breast cancer patients in Sub Saharan Africa. The real-time survival rates presented here provide alarming evidence that downstaging and public health care interventions are needed in order to prevent breast cancer deaths in this region.
Understanding women's perspectives on breast cancer: Knowledge, intentions, and care-seeking in Tanzania

Anne F Rositch¹, Ophira M Ginsburg², Liuye Huang¹, Christina A Chao¹, Kala Visvanathan¹ and Nestory Masalu³. ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Perlmutter Cancer Center and Section for Global Health, NYU Langone Health, New York, NY and ³Bugando Medical Centre, Mwanza, Tanzania, United Republic of.

Background: The rate of increase and absolute burden of breast cancer is higher in less developed countries, with over 1 million projected new cases per year in low- to middle-income countries (LMICs) alone by 2020. As these countries develop clinical programs to combat the increasing incidence, understanding women's perspectives on breast cancer and care-seeking are key to successful implementation.

Methods: We conducted a community-based survey using convenience sampling of women aged 30 and older in Mwanza, Tanzania to assess knowledge and understanding of breast cancer, including causes and symptoms, and intentions regarding care-seeking for a breast health issue.

Results: Among 1,101 women, with a median age of 38 (IQR: 31-46), 75% of women have heard of cancer. Women self-evaluated their knowledge of cancer from 1 (no knowledge) to 10 (extremely knowledgeable) with a median response of 2 (IQR: 1-4) for women age 30-39 and 3 (IQR: 1-4) for women 40 and older (p=0.01). Only 14% felt they knew any signs or symptoms of breast cancer, with no difference by age, but 56% were fairly or very confident they'd notice a change in their own breasts. Overall, 47% said they'd be somewhat likely and 26% said they'd be very likely to seek care if they noticed a change. In fact, 18% reported having a clinical breast exam, 3% a breast ultrasound, and 2% a mammogram. Among 27 women who reported breast-related care, 78% said the reason they sought care was because they'd had a breast exam (n=21), 52% because they had education about breast exams (n=14), and 48% because they had breast symptoms (n=13). Half of the 27 women who sought care ultimately got a breast diagnosis: 5 were cancer whereas 9 were not cancer. All women diagnosed with cancer said they received treatment.

Conclusions: The success of efforts to improve early diagnosis, the cornerstone of achieving clinical down-staging and ultimately, reduced mortality depends on women being aware of breast cancer, its causes, signs and symptoms, and being encouraged to seek care for breast concerns. Fortunately, the majority of women said they would seek care if they noticed a change in their breasts but the low levels of cancer knowledge and symptoms of breast cancer highlight the need for community education and awareness campaigns.
The effect of the affordable care act on the initial stage of presentation of breast cancer in a safety-net hospital

Ana C Sandoval Leon¹, Swapna Ghanta¹, Angelique Richardson¹, Susan Kesmodel¹ and Judith Hurley¹. ¹University of Miami, Miami, FL.

Background: There are disparities in breast cancer (BC) diagnosis. Black and Hispanic women have a lower rate of screening mammography while the uninsured are less likely to seek medical care even if a palpable mass is found in the breast. Jackson Memorial Hospital is the Safety-Net Hospital that serves the 2.5 million residents of Miami-Dade County which is the most populous county in the State of Florida. The Affordable Care Act (ACA) was signed into law on March 3, 2010 and the goal was to increase the number of insured individuals. In January 2011, it was mandated that health insurance providers cover the cost of screening mammograms. The decision to expand Medicaid was left to the individual states. Florida did not expand Medicaid coverage. Prior to the implementation of the ACA it was estimated that 25-35% of the residents of Miami-Dade County were uninsured or underinsured. By January 2017, more than 1.3 million Floridians had signed up for health insurance through the ACA. Currently almost one in five Americans receiving health coverage via Healthcare.gov or the Spanish language version, CuidadodeSalud.gov, resides in Florida. South Florida is home to the eight congressional districts with the highest concentrations of ACA enrollees in the US. The top 38 zip codes for ACA sign-ups in Florida are in South Florida. We postulated that evaluating the number of patients diagnosed, the stage at which they are diagnosed and the type of insurance used for the period of time 6 years before (2007-2012) and 4 years after the implementation of the ACA (2014-2017) should give a picture of the effect of the ACA on breast cancer diagnosis in an underserved population.

Methods: A retrospective review of patients diagnosed with invasive and in situ breast cancer at the Breast Diagnostic Center at Jackson Memorial Hospital between 1/1/2007 – 12/31/2017 was approved by the University of Miami IRB. We collected data including: age, stage at diagnosis and type of insurance. In keeping with other similar studies, the year 2013 was excluded since it was a transition period. The trends were compared using ANOVA and chi-squared tests.

Results: A total of 2155 patients were analyzed. The absolute number of patients with stage 0 seen every year remained stable (30 per year) throughout the time period. The percentage of patients with Stage 0 increased from 12.5% to 16.02% (p=0.049). Both the absolute number and percentage of patients with stage IV decreased, from 15 to 8 patients per year (6.42% to 4.12% (p=0.016)). The total number of patients diagnosed yearly with breast cancer decreased from 233 to 186 (p= 0.005). The absolute number and percentage of insured patients increased from 75 to 126 patients per year (23.5% to 38.3% (p= 0.02)).

Conclusions: Fewer patients were diagnosed with breast cancer at the safety net hospital in Miami-Dade County after the initiation of the ACA. More patients had insurance and there was a stage shift towards lower stage at presentation. Availability of insurance to residents of Miami-Dade County decreased the burden on the safety net hospital and resulted in the diagnosis of lower stage breast cancer.
Needle-to-knife wait time and impact on pCR in patients undergoing neoadjuvant chemotherapy for breast cancer

Valerie Lai¹, Omar Hajjaj², Stephen Chia² and Christine Simmons². ¹UBC, Vancouver, Canada and ²BC Cancer Agency, Vancouver, Canada.

Introduction: In the setting of pre-operative neoadjuvant chemotherapy (NAC) for the treatment of breast cancer, it is important to ensure coordination between medical and surgical oncology. A study by Sanford et al. show that patients receiving surgery >8 weeks after NAC have worse overall survival. As NAC continues to expand its role in breast cancer treatment, a closer look at the maximal acceptable time between NAC and surgery becomes more important. We wished to assess the impact of time between last dose of chemotherapy and surgery on pathological complete response (pCR), disease free survival (DFS), overall survival (OS), and surgical complications.

Methods: A cohort study was conducted utilizing the BC Cancer Agency's prospective neoadjuvant database, located in Vancouver, BC. Patients were selected if they had undergone NAC with curative intent for treatment of breast cancer, followed by surgical resection. Patients who received neoadjuvant radiation and/or hormone therapy were excluded. Patients were divided into three groups: those who had surgery <4 weeks from last dose of chemo, 4-8 weeks from last dose, and >8 weeks from last dose. Charts were audited for demographic data, tumour characteristics, and complications from surgery. Data was analyzed using a Chi Squared test to determine any differences in pCR, OS, DFS, and surgical complications, between the three different time intervals.

Results: 347 patients were identified and included in this study. The median time to surgery after last dose of chemotherapy was 4.86 weeks (range 0.86-22.86 weeks). The percentage of patients that achieved pCR was 31.3%, 30.5%, and 28.6% in the <4 weeks, 4-8 weeks, and >8 weeks groups respectively (p= NS for all comparisons). There was no difference in pCR observed between the three groups based on receptor status. At the median follow up of 3 years, DFS was 85%, 85.8%, and 85.7% in all three groups. Likewise OS was 95%, 90%, and 89% respectively. The rate of surgical complications are 16%, 23.4%, and 21.4% for the three groups respectively (p=NS).

Conclusions: This study demonstrated no difference between receiving surgery <4 weeks, 4-8 weeks, or >8 weeks after last dose of NAC on pCR, survival, or surgical complications. This finding was preserved in all receptor subtypes. This has important implications for resource allocation. This data may also help in counselling and easing patient anxiety in terms of the urgency (or lack thereof) and wait times for surgery. Subsequent studies with larger sample sizes will help to ensure that clinical differences in outcomes are not affected by wait times.

Overcoming barriers to achieve a successful breast cancer patient recruitment: Professionals' views

Ana Casas¹, Xavier González², Marta Capelán³, Josefa Morales², Marta Fabián², Eva Ciruelos⁵ and Giovanna Gabriele⁶,⁷
¹Hospital Virgen del Rocío, Sevilla, Spain; ²SOLTI Breast Cancer Research Group, Barcelona, Spain; ³Institut Oncològic Dr. Rosell, Hospital General de Catalunya, Sant Cugat del Vallès, Barcelona, Spain; ⁴Hospital Vall d’Hebron, Barcelona, Spain; ⁵Hospital 12 de Octubre, Madrid, Spain; ⁶Pompeu Fabra University, Barcelona, Spain and ⁷FocusHealth Research Institute, Barcelona, Spain.

Accurate recruitment in performing clinical trials is crucial to avoid delays in the availability of potential beneficial treatments for patients. However, optimal strategies to improve it remain elusive and highly variable. The aim of this study was to identify the factors affecting recruitment from a multi-professional approach.

Methods: A convergent mixed method study was used, including key informant in-depth interviews (n=13), 5 focus groups (n=40) and a 209-item Likert-scale survey for the measurement of a whole array of variables of interest (i.e. job attitudes, job satisfaction, job stressors and social status). A purposive sample of professionals from thirty-three clinical trial sites in Spain were targeted. Qualitative data were analyzed alongside quantitative data to document patterns and modifiers of recruitment performance. Audio material was recorded, transcribed verbatim and analyzed using the framework method.

Findings: Pattern observed in qualitative data was confirmed in quantitative analysis. A total of 32 key barriers to successful patient recruitment were identified and clustered in three categories. The most commonly reported barriers and facilitators regarding a multifactorial approach were: System/organization: Counting on experienced recruiters and having a strong team-workforce awareness (92,3%); automated recruitment software, scientific culture, recruiting philosophy, adequate workload demands (88%); high stimuli and interprofessional trust (84%). However, lack of time devoted to clinical research in favor of assistance demands, excessive workload and bureaucratic tasks were the most salient stressors to fulfill professional research and recruitment responsibilities (54%). Working team conditions: Insufficient workforce support as well as high employee turnover contributed to emotional exhaustion and depersonalization and to a lower personal accomplishment (15%). Interpersonal relations affected not only motivation and performance but professionalism satisfaction with outcomes. Professional recruiter characteristics: Professionals with a high level of expertise and academic specialization (>5 years), greater active involvement in relevant clinical trials just as interprofessional prestige and recognition showed a greater satisfaction. Consequently, they were prompted to intensify their efforts to fulfill recruitment. The more effective clinical research settings were those better aligned with attributes for becoming high recruiters and with better multi-professional articulation. Suggestions to improve recruitment included providing professionals with devoted time for research, setting up collaborative research agreements, building a clinical research network, collaborative tumor registries, clinical trials data sharing resources, multidisciplinary functional units and committees, flexible staffing models and empowering oncologists/managers leadership.

Conclusions: This study provided useful understanding of how to maximize patient recruitment at clinical research sites. Strong team-workforce and adequate workload were the most important identified factors for achieving it. Results will be used to inform professionals and stakeholders of the next steps needed and to engage them to fulfill accurate recruitment.
Analysis of barriers to clinical trial accrual in an NCI-designated comprehensive cancer center: Results of identifying clinical trial gaps

Zoneddy Dayao¹ and Jaclyn Nemunaitis¹. ¹University of New Mexico Comprehensive Cancer Center, Albuquerque, NM.

Background: NCI-designated centers struggle to meet the 10% minimum accrual benchmark even for common malignancies such as breast cancer. The University of New Mexico Comprehensive Cancer Center (UNMCCC) average annual breast cancer trial accrual rate is approximately 11%, despite an average of 20 open breast cancer trials. Many published barriers were perceived to account for UNMCCC's low accrual including suboptimal screening, patients' unwillingness to participate, and disparities arising from socioeconomic and cultural barriers related to the large minority patient population. We sought to identify the true barriers to breast cancer therapeutic trials accrual to strategically formulate targeted solutions.

Methods: In 2016, a retrospective study was performed to review all breast cancer patients from UNMCCC's 2014 NCI Data Table 3. Barriers were classified into (a) trial specific, in which no trial was available or the patient was ineligible (b) patient specific, in which an appropriate trial was available but the patient declined participation (c) provider specific, in which screening was not documented.

Results: 145 cases were retrospectively evaluated. 6% declined participation, 13% were ineligible and 4% were not screened. Only 11% were enrolled in the 21 open trials.

No trial was available for 66% of patients. Out of this group, the majority of cases (68%) were stage 0/ I/ II (DCIS 12% LCIS 4%, stage I/II node negative, HR+, Her2- 52%), 17% were triple negative and 15% were HER2 positive.

The findings showed that despite the extensive clinical trial menu, the trials did not in fact adequately match the majority of the patient population who largely had early stage disease. This was identified as the main barrier to accrual. This resulted in a change in trial prioritization. Previously, the majority of trials were for advanced disease. From 2016-2018, the priority shifted to opening trials focused on early stage HR+, Her2 negative population. Investigator initiated, pharmaceutical, NCTN trials and symptom control trials for this population were opened.

As of December 2017, Data Table 3 accrual showed that 19% (70/353) new breast cancer patients were enrolled. This represents an increase in accrual from 11% to 19%. Of these, 28% (20/70) had early stage HR+ Her2 negative disease.

As of 2018, therapeutic trials that include early stage HR+, Her2 -, node negative disease now comprise 30% of the UNMCCC breast cancer trial menu.

Conclusion: Detailed analysis of UNMCCC's breast cancer Data Table 3 showed that contrary to prior perceptions, the main accrual barrier was not ineffective screening, patient ineligibility or unwillingness to participate. The main barrier was that the extensive trial menu did not match the patient population. A large gap in the clinical trial menu was identified. Published barriers to clinical trial accrual may not necessarily hold true for a specific institution. A disease-specific root cause analysis can facilitate development of tailored solutions. A shift in strategy in trial prioritization resulted in an increase in annual breast cancer trial accrual from 11% to 19%.
Tolerance of HER-2 directed therapy for early stage breast cancer in a predominantly Hispanic population with high prevalence of cardiovascular risk factors

Sumit Gaur¹, Meghan McAlice¹, Ahmed Alshaban¹, Antonyos Mahfoud¹, Javier Corral¹ and Alexander Philipovskiy¹. ¹TTUHSC-El Paso, El Paso, TX.

Introduction:
Trastuzumab based therapy is recommended for patients with early stage HER-2 overexpressing breast cancer, because it improves survival. Significant racial disparities exist in the receipt of trastuzumab with minorities being 25% less likely than whites in being treated with it. (Reeder-Hayes K et al, JCO 2016; 34:2003-2009).
Trastuzumab can affect cardiac function. Cardiac complications associated with trastuzumab are influenced by age and pre-existing risk factors including obesity, hypertension and diabetes mellitus. These co-morbidities occur more frequently in medically underserved minority populations and might influence the practitioner's decision regarding withholding the drug. We previously identified a high prevalence of metabolic syndrome and obesity in our predominantly Hispanic, medically underserved patient population (SABCC 2015 abstract P1-09-07)). For this study, we analyzed the echocardiographic data and cardiac complications associated with trastuzumab use in this patient population.

Methods:
All patients diagnosed with early stage (stage 1, 2 or 3) HER 2 positive breast cancer between Jan 1st, 2010 and Jan 1st, 2015 at our institution were identified. Age, race, body mass index, pre-existing cardiovascular risk factors, and antihypertensive medication use was collected. Tumor size, nodal status, ER, PR and HER 2 status was recorded. All echocardiograms obtained were reviewed for ejection fraction changes. Repeated measures one sided ANOVA was used to analyze changes in EF. Hospitalization for cardiac complications was recorded. Early interruption of planned therapy and its reasons were recorded. Study was approved by the institutional IRB.

Results:
Sixty patient were treated with trastuzumab based chemo immunotherapy over the study period. 93% were Hispanic, median age was 61 years (Range 31-83), 40% had hypertension, 35% had dyslipidemia, 35% had glucose intolerance or type II diabetes mellitus and 70% were overweight or obese. 33% were dependent on charity care. 26% had stage 1, 37% had stage 2 and 37% had stage 3 cancer. Docetaxel, carboplatin, trastuzumab (TCH) was the most commonly used regimen (63%) followed by doxorubicin, cyclophosphamide, paclitaxel and transtuzumab (28%).
Ten patients (16.6%) required early discontinuation of cytotoxic chemotherapy. Only 1 patient was unable to complete planned 1 year of trastuzumab due to declining ejection fraction. There were no hospitalizations related to cardiac events during therapy. Trastuzumab based treatment elicited statistically significant changes in LVEF over time, F (2,98) =13.974, p<.0005, with LVEF decreasing from 65.4±.844 prior to therapy to 64.7±.724 during 3-6months of therapy and 62.2±.81 at the end of therapy. Two patients had a decline in LVEF ≥ 10%. Of these, 1 resolved at follow up ECHO in 6 weeks.

Conclusion
In a predominantly Hispanic, HER 2+ breast cancer cohort, with a high prevalence of cardiovascular risk factors and limited health care access, we found that the vast majority were able to complete 1 year of trastuzumab without significant cardiac complications. As trastuzumab improves survival, practitioners should adhere to national guidelines regarding its use as much as possible.
Introduction
Preoperative chemotherapy can demonstrate an individual's response to the chemotherapeutic regimen by comparing the amount of cancer at presentation to the amount remaining after treatment. Multiple previous studies have demonstrated that the amount of residual cancer, or final pathologic stage, is a better indicator of prognosis than the initial stage at presentation. Tumor infiltrating lymphocytes have been recognized in breast cancer, and when found concentrated in breast cancer specimens, have been associated with a good prognosis. Breast cancer is not only a heterogeneous disease, but also displays varied presentation and behavior in patients of different race/ethnicities.

This study was performed to evaluate factors which predict response to chemotherapy. The effectiveness of different chemotherapeutic regimens, the effect of breast cancer subtype, and tumor infiltrating lymphocytes (TILs) were evaluated in our racial/ethnic minority population.

Methods
All patients at the safety net institution in Phoenix, AZ who underwent preoperative chemotherapy from 2002 to 2017 and had tissue available for evaluation were included in the study. Response to chemotherapy regimen was recorded. Pathologic complete response (pCR) was defined as no invasive cancer in the breast and lymph nodes in the final pathologic specimen. Breast cancer subtypes were divided based on IHC and FISH testing. Luminal subtypes were classified based on Ki67 (>15%) and/or PR (<20%) for Luminal B. Her2 subtype was defined as Her2 IHC 3+ or Her2 FISH amplified. Triple negative breast cancer (TNBC) was defined as ER and PR (<5%) and Her2 negative. TILs concentration was determined from fixed formalin paraffin embedded (FFPE) core needle biopsy specimens.

Results
A total of 259 patients were included in the study. The mean age was 45 years. 80% of the population were racial/ethnic minorities. The vast majority (94%) were underinsured or uninsured, with 75% uninsured. The mean clinical tumor size at presentation was 6cm. 52% presented at clinical stage 2 while 48% presented at clinical stage 3. The overall pCR rate was 32%. pCR rate was impacted by breast cancer subtype with TNBC 52% and Her2 38% showing a better response to chemotherapy, while Luminal B was 16% and Luminal A 2% (p < 0.05). In TNBC, chemotherapy regimens with antracycline and docetaxel may have improved efficacy with pCR of 56% (p = 0.05). In the subgroup available for TIL evaluation, breast cancer subtype appeared to show similar importance with pathologic complete response rates of TNBC 50%, Her2 44%, Luminal B 12%, and Luminal A 0%. TIL appeared to affect the likelihood of pCR. When TIL were less than 5% the pCR rate was 16% compared to when there were TIL of at least 5% or more the pCR rate was 41% (p < 0.05).

Conclusions
In our racial/ethnic minority population, breast cancer subtype and chemotherapy regimen did affect likelihood of pathologic complete response. Tumor infiltrating lymphocyte concentration as low as 5% may indicate a higher likelihood of pathologic complete response and could be used as an additional factor in the evaluation of patients for preoperative therapy.
Genetic counseling in an emergent country: Disparity in access to genetic cancer risk assessment for breast cancer within the Mexican population

Saul Campos-Gomez¹, Guillermo Pacheco-Cuéllar¹, Karen Campos-Gomez¹, Maricela García Garcés¹, Juan Valdes Andrade¹ and Jose Luis Barrera Franco¹. ¹Centro Oncologico Estatal ISSEMyM, Toluca, Mexico.

**Background:** Breast cancer (BC) is the most common malignancy in Mexico. 5-10% of BCs are hereditary. In Mexico the lack of resources, including geneticists/genetic counselors and the cost of genetic testing, are barriers to set up GCRA (Genetic Cancer Risk Assessment) clinics. Besides few public health programs offer GRCA to their beneficiaries; moreover 62% of Mexican population lacks health insurance. Seguro Popular (SP) offers health services to 50 million of low-income Mexicans without health coverage, but SP doesn't cover GRCA nor testing for BC. COEI offers services to two different populations: COEI Beneficiaries (CB) and SP. GCRA and genetic testing are only covered for CB.

**Methods:** This retrospective study compared clinical and demographic data between these cohorts. From Nov 2016 to Dec 2017, all new BC patients (pts) were referred to GRCA according to NCCN guidelines. SP pts were also invited to participate; we provided them voluntary this service. We collected demographic, familial and medical data. Genetic testing was offered only to some CB pts because of our limited budget. Descriptive and nonparametric statistics were used.

**Results:** We compared the data of 74 cases: 51 were CB and 23 SP pts. The average age at diagnosis was 41.8, 18(24.3%) of tumors were triple negative. SP pts tended to be younger, and with more advanced disease than the CB population but without statistical differences. SP group was less educated than the CB pts (p > 0.001).

**Conclusions:** Except for education level, no other difference was seen. More research is needed to explore the relationship with the lower degree of education, clinical stage and health care access. Our sample is small, but it reflects the lack of access to GCRA services for low income and less educated pts across the country. GCRA could benefit SP group, to modify habits, start promptly and adapted screening, and have the choice to undergo genetic testing. If we consider the high percent of population who lack of GRCA services, we are missing opportunities to inform, and promote early detection of cancer.
Recommendations to improve the lived experience of early stage and metastatic breast cancer patients in Canada

Jenn Gordon¹, Cathy Ammendolea¹, Niya Chari¹, Rebecca Armstrong¹ and Wendy Hall¹. ¹Canadian Breast Cancer Network, Ottawa, ON, Canada.

Introduction: In 2017, the Canadian Breast Cancer Network (CBCN) undertook two surveys of Canadians who have experienced a breast cancer diagnosis to better understand the lived experience of patients and what opportunities exist to improve support for patients, survivors and their families and minimize the impact of this disease. There were 278 people diagnosed with early stage breast cancer, defined as stage I, II or III for the purpose of this report, and 180 people living with metastatic breast cancer, or stage IV breast cancer, who responded to these surveys.

Results: The survey data shows that while patients feel supported and well cared for in certain aspects there are still significant opportunities for improvement. CBCN has identified five overarching factors that could greatly improve health outcomes and the quality of life of Canadians who experience a breast cancer diagnosis.

1. Improved Educational Resources: The quality and availability of patient education has increased over the past couple of decades; however, there are still some patient friendly educational resources including, specific resources for newly diagnosed metastatic breast cancer patients; decision aids that support breast cancer surgery and post-surgery decisions; navigation of financial resources; treatment timelines and recovery expectations; private insurance navigation and information on dying-well.

2. Increased Access to Treatments: This challenge was specifically identified and vocalized by people living with metastatic breast cancer. Efforts need to continue to shorten the drug approval process time, increase equitable access to new medications for all Canadians, and ensure equitable access for take home oral cancer medications.

3. Increased Access to Information: Information available to patients about their health and treatment has increased; however, there is still information that isn't always communicated to patients that would help them make informed decisions about their health. This includes information about breast density, palliative care options and information around clinical trials.

4. Integrated Systemic Supports: The health care system as a whole is responsible for many of the services and supports that patients need to achieve optimal health and manage their breast cancer; however, these supports can be challenging to navigate and are sometimes lacking. Supports that need to be addressed at a systemic level include developing survivorship care plans for early stage patients, patient navigation, communication tools to support general practitioners during the diagnosis process, access to psychosocial professionals and increased Employment Insurance Sickness Benefits.

5. Increased Awareness and Understanding of Metastatic Breast Cancer: A lack of accurate statistics and overall awareness of metastatic breast cancer makes it challenging to truly understand the impact of this disease and also leaves people living with an incurable form of breast cancer feeling isolated and disconnected. Accurate statistics and increased awareness would help further the understanding of the impact of this stage of breast cancer and better support those with it.
Impact of public health insurance “Seguro Popular” on breast cancer recurrence at Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán (INCMNSZ), Mexico City

Lorelí Mejía-Fernández¹, Heriberto Medina-Franco¹ and Alejandra Armengol-Alonso¹. ¹Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.

Introduction. Public health insurance called Seguro Popular (SP) for breast cancer treatment (BCT) was instituted in Mexico in 2007. Our third level center was enrolled until 2011. SP covers systemic BCT (WHO 20th model list essential medicines). The aims were: 1) Describe frequency and type of breast cancer recurrence (BCR), 2) compare which factors were contributing to recurrence of breast cancer patients (pts) before and after the implementation of SP. Methods. Pts with diagnosis of breast cancer (BC) from 2004 to 2018 were analyzed and pts with BCR whom primary tumor (PBC) was treated and followed at INCMNSZ were recruited. They were divided into two groups according to access to SP: pts without Seguro Popular (non-SP) and pts with SP. Xi-square, non-parametric tests and Kaplan-Meier curves (log-rank test) were used. Logistic regression was done for multivariate analysis. A p-value <0.05 was considered significant. Results. Between 2004 and 2018, 929 pts with BC were diagnosed; 438 non-SP and 473 SP. Ninety-one (9.7%) had a BCR (loco-regional or distant) during this period. Median follow-up was 125 months. The BCR proportion was higher within non-SP than in SP (74 (16.8%) vs 17 (3.5%) pts) (p=<0.05). Median age at diagnosis was higher in non-SP (p=0.028). Distant relapses were higher in non-SP than in SP (44 (59.4%) vs 8 (47%) pts). St Gallen 2017 Luminal A/B subtypes were most common in non-SP compared to SP where Basal-like subtype was higher (p=0.048). Luminal-A subtype had the best survival among non-SP compared to SP in which HER2 non-luminal had the higher survival (p<0.001). Conclusions. Experience with SP at our center shows promising results in the improvement of BCR. Access to adequate systemic management (hormone-blocking and HER2 targeted therapy) has a positive impact on recurrence, disease-free survival, and cancer-specific global survival. A longer follow-up time is required in the SP group (prospective cohort) to confirm these findings, especially in luminal tumors with late recurrence risk. Efforts should be made in the Mexican public health system to secure basic and continuous access to BCT.
Breast cancer in Colombia: A growing challenge for the health care system

Carlos Duarte¹, Alejandro Salazar¹, Kathrin Strasser-Weippl², Esther de Vries³, Carolina Wiesner¹, Lindsay Krush⁴,⁵ and Paul E Goss⁴,⁵. ¹Instituto Nacional de Cancerología, Bogota, Colombia; ²Wilhelminen Hospital, Vienna, Austria; ³Pontificia Universidad Javeriana, Bogota, Colombia; ⁴Global Cancer Institute, Boston, MA and ⁵Massachusetts General Hospital, Boston, MA.

INTRODUCTION
Colombia has a population of roughly 49 million people of predominantly Mestizo ethnicity. Cancer has become a growing public health problem in Colombia with nearly 71,000 newly diagnosed malignant tumors per year. It is expected that by 2035, 150,000 new cases of cancer will be diagnosed, making Colombia an intermediate country with regards to global cancer incidence according to IARC.

METHODS
Epidemiological data on breast cancer is scarce and varied due to multiple sources of information. These numbers are obtained thru population-based cancer registries that represent 4 distinct regions of the country. Other data originate from non-governmental institutions and healthcare providers within Colombia. The Colombian National Cancer Institute publishes a Cancer Mortality Atlas annually.

RESULTS
Local cancer registries have shown increases in breast cancer incidence in Colombia. In 2007, age-standardized incidence rate was 27.8 per 100,000 persons increasing to 49.7 cases per 100,000 persons in 2012. Approximately, 2200 women die every year in Colombia due to breast cancer with rates increasing historically, but now are stabilizing. Advanced breast cancers are most frequently found among women without health insurance, while early breast cancers are usually found among working women and those covered by private health insurance. Early breast cancer screening was made mandatory as public policy in the year 2000. However, only 30% of health care coverage was reported, translating to very low coverage by opportunistic screening programs with only 33% of women having had a mammography. In 2012, a National Cancer Control Plan was planned and implemented. It aims to increase early stage cancer diagnosis, increase biannual screening coverage, and guarantee timely access to diagnosis and treatment. A national health survey in 2015 showed only 48% of women had an annual mammographic screening. Multiple disparities have been found with regards to screening and early diagnosis such as economic strata, health insurance coverage, origin, and accessibility. Specifically, data shows that 23% needed to travel in order to obtain access to mammography. Often it is necessary for some patients to sue healthcare insurance systems to obtain specific health care, causing an increase in time to diagnosis and treatment. In 2016, on average a 90-day period was reported from time of onset of symptoms to suspected diagnosis of breast cancer, while the time to the initiation of treatment was 100 days for chemotherapy and close to 120 days for surgery.

DISCUSSION
These data serve to impact the landscape of breast cancer and improve patient outcomes in Colombia. While the National Cancer Plan has led to major changes, a big challenge remains related to the delays between suspicion of breast cancer and diagnosis and treatment. Quality of care provided by private and public insurance administrators is also of concern. General practitioners should receive more detailed training in breast cancer detection and management. The healthcare system should provide quality cancer care with urgent improvement in mammography, especially in more rural areas. Widely, more timely and appropriate follow-up is needed.
Non-clinical drivers of variation in preoperative MRI utilization for breast cancer

Linda M Pak1,2, Amanda Banaag3,4, Tracey P Koehlmoos4, Adil H Haider1,2 and Peter A Learn4. 1Center for Surgery and Public Health, Harvard Medical School and Harvard School of Public Health, Brigham and Women's Hospital, Boston; 2Brigham and Women's Hospital, Boston; 3Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda and 4Uniformed Services University of the Health Sciences, Bethesda.

Background: Preoperative MRI utilization in breast cancer treatment has increased significantly over the past two decades but its use continues to have inter-provider variability and disputed clinical indications. The objective of this study was to evaluate non-clinical factors associated with preoperative breast MRI utilization.

Methods: This study utilized claims from the Military Health System Data Repository (MDR) on TRICARE Prime beneficiaries, from fiscal years 2006-2015. TRICARE provides health benefits for Active Duty service members, retirees, and their dependents at both military (direct care with salaried physicians) and civilian (purchased care with fee-for-service physicians) treatment facilities. We studied patients aged 25-64 years old with a breast cancer diagnosis who had undergone mammogram/breast ultrasound alone or with subsequent breast MRI prior to surgery. Patient demographics and treatment characteristics were abstracted from the data. The National Center for Health Statistics (NCHS) urban-rural classification was used to determine the urbanization level of the treatment facility. Adjusted multivariate logistic regression tests were used to identify independent factors associated with preoperative breast MRI utilization.

Results: Of the 25,656 identified patients, 64.4% of patients (n=16,511) received preoperative mammogram/breast ultrasound alone while 35.6% of patients (n=9,145) underwent additional MRI after mammographic and/or ultrasound imaging. On multivariable analysis, younger age, presence of two or more comorbidities, active duty or retired beneficiary category, officer rank (surrogate for socioeconomic status), Air Force service branch, metropolitan location, and purchased care were associated with increased likelihood of preoperative MRI utilization. Nonmetropolitan location and Navy service branch were associated with decreased MRI use.

Conclusions: After controlling for expected clinical risk factors, patients were more likely to receive additional MRI when treated at larger metropolitan facilities or through the purchased, fee-for-service system. Both associations may point toward non-clinical incentives to perform MRI in the treatment of breast cancer.
Marital status is associated with late stage presentation in patients with breast cancer

Cecil M Benitez, Katy E Balazy, Rie von Eyben and Kathleen C Horst. 1Stanford University, Stanford, CA.

Objective: To determine whether marital status is associated with late stage presentation for breast cancer patients.

Materials/Methods: Patients with breast cancer treated with radiation therapy at a single institution from 2012-2017 were identified (n=1060). There were 189 patients with stage 0/DCIS, 442 with stage I, 318 with stage II, 74 with stage III, and 38 with stage IV disease. Patients were categorized by marriage status as single, married, divorced, or widowed. A logistic regression model was run using stage as the outcome to analyze odds ratios for late stage presentation (stages III and IV) based on marital status. The model included age, ethnicity/race, insurance, marital status, and language. Additional interactions between age and ethnicity/race, and ethnicity/race and insurance improved the fit of the model and were also included. All odds ratios were interpreted against the reference subset defined as white, married, English-speaking patients with public insurance.

Results: There was a significant association between marital status and stage of presentation, most notably for widowed patients. Widowed patients have 2.04 odds of presenting with late stage disease compared to married patients (95% CI 1.20-3.47). Additionally, single patients present at an earlier stage than widowed patients, and have 0.50 odds of late stage disease compared to widowed patients (95% CI 0.28-0.91). There was a trend towards divorced patients having a higher odds of late stage presentation, however, it was not statistically significant. Divorced patients had 1.33 times the odds of having late stage disease compared to the married patients (95% CI 0.90-1.96), and 1.30 times the odds of having late stage disease compared to the single patients (95% CI 0.82-2.06). However, relative to widowed patients, the divorced patients have lower odds of presenting with late stage disease (OR=0.65, 95% CI 0.35-1.21). Interestingly, there is no statistically significant difference between single and married patients for stage of presentation (OR=1.03, CI 0.75-1.41).

Conclusion: Marital status is correlated with late stage presentation, especially for widowed patients. Interestingly single and married patients had almost identical probabilities of presenting with all stages of disease. They had the highest probability of having stage 0/DCIS or stage I disease, and the lowest probability of stage III or stage IV disease. Divorces had a trend towards late stage presentation, with a smaller probability of stage 0/DCIS and stage I disease, and greater probability for stage III and stage IV disease. The biggest difference was seen for widowed patients who had the smallest probability of stage 0/DCIS or stage I disease, and the greatest probability of having stage III or stage IV disease. Widowed patients had higher odds of presenting with late stage disease than both single patients and married patients. It remains to be explored why this population is more vulnerable to late stage breast cancer presentation than their single, married, and divorced counterparts.
The value of patient navigation in breast cancer being tested in Rio de Janeiro, Brazil

Sandra Gioia1, Cristiane Torres1, Juliana Cavalcanti1, Lucia Brigagao2, Tania Proencio2, Lindsay Krush3 and Paul Goss4. 1Brazilian National Cancer Institute, Rio de Janeiro, Brazil; 2Rio Imagem, Rio de Janeiro, Brazil and 3Global Cancer Institute, Boston, MA.

OBJECTIVES: The main objective of this Patient Navigation Program in Rio de Janeiro (PNP Rio), Brazil, is to promote adherence to the "60 Day Law", which states that all patients with cancer within the public system should start treatment within 60 days after diagnosis of cancer. Thus, the objectives are: 1.) to establish feasibility of PNP in this setting; 2.) to identify barriers to compliance the Law of 60 days and 3.) to ensure that at least 70% of recruited breast cancer patients begin treatment within the mandated 60-day period. One report by FEMAMA states that only 30% of breast cancer patients in Rio de Janeiro to initiate treatment within the 60-day mandate.

METHODS: From August 2017 to May 2018, one hundred patients aged 33-81 years (mean age 59 years) were recruited for navigation at Rio Image - an advanced breast cancer diagnosis center administered by the state health secretary and located in the capital city of Rio de Janeiro, attending patients from the public system from all 92 municipalities in the state. Patient Navigator (PN), a trained social worker, starts navigation from diagnosis, administering questionnaires to collect: patient population data, dates and information of historical milestones, and patient satisfaction. Patients were followed up by phone, e-mail or text message to identify barriers to initiation of treatment.

RESULTS: Patients presented staging 0-I (17%), II-III (78%) and IV (5%). There were two deaths related to breast cancer in this group. All patients reported at least one barrier, ranging from 2 to 12 barriers (M=5). The barriers to compliance with the "Law of 60 days" were: Fear and fatalistic thoughts (99%), Financial problems (79%), Uncoordinated health care (76%), Health professionals ignore the Law of the 60 days (75%), Need to do staging exams again (52%), Concern about communicating with medical staff (52%), Transport (42%), Difficult in obtain surgical risk consultation (12%), Line of surgeries in hospitals (12%), Difficult of insertion in the regulation system in Primary Care(11%), Patient cannot express herself (5%), Social support(4%), Absent of the immunohistochemistry panel (4%), Cognitive problems (3%), Comorbidities (2%). The PNP had 100% patient satisfaction and in 60% of the cases it helped the patients to start treatment within the period established by law.

CONCLUSIONS: In summary, PNP Rio generated a positive experience for patients in the public health system because it is an intentional and proactive process of assisting the individual through the cancer system, accessing services and actively overcoming barriers to quality care. The PNP Rio did not achieve the success rate of 70% of compliance with the Law as intended (achieved 60%). However, the barriers that the PN can not overcome such as lack of human resources and medical supplies, were informed to health authorities and hospital administrators. This is an opportunity for discussion of reallocation of funds, focusing on the use of scarce resources in prevention and early treatment rather than late-stage disease. In the Brazilian context, PNP may represent an opportunity to implement existing legislation adequately, and as such, would have great potential for integration at the federal, state, and local health systems.
Exploring the role of social support and adjuvant endocrine therapy use among breast cancer survivors

Gabriela Toledo4852, Carol Y Ochoa4852 and Albert J Farias4852. University of Southern California, Los Angeles, CA.

Background: The side-effects of adjuvant endocrine therapy treatment (AET) are one of the main reasons why women discontinue therapy. Helping women manage the side-effects may improve adherence since only half are adherent for 5-years. Generally, patients experience a decline in social support from family/friends and medical providers when beginning AET because the severity of the side effects are not as physically apparent as those associated with other cancer treatments. Therefore, the objective of this study is to explore the role of social support and identify how it is delivered during the on-going management of AET.

Methods: We conducted semi-structured in-depth interviews with breast cancer patients (n=19) who had filled a prescription for AET in the previous 12 months. Women were recruited from Los Angeles, California and Houston, Texas between 2014-2015. Interviews were audio recorded and professionally transcribed. Interview questions were designed to prompt discussion about experiences with AET and examine how sources of support affect the management of AET drugs. We used an integrated approach to develop a code structure, which was applied to interview transcripts using qualitative inductive reasoning to identify major themes and subthemes. The study team met regularly, in an iterative process, to redefine the codebook by adding, removing, and revising codes to capture emerging themes. We grouped social support into four major categories to identify the sources and delivery of support: emotional, informational, instrumental, and appraisal.

Results: Patients most commonly described informational support from their medical providers via consultations or phone, during which providers would explain the purpose, benefits, and side-effects of AET in a manner that they could understand. Many patients confided in their health providers when struggling with the side-effects of AET, and those who were well-received expressed trust and confidence in their physician's recommendations. Women also discussed other noteworthy sources of informational support through technology, survivorship groups, family/friends, and religious groups. Emotional support was an equally important type of social support as patients discussed the need for ongoing reassurance, communication, and empathy to help them deal with the stressors of managing their side effects, which they received from family, survivorship groups, and different forms of spirituality and religiosity but could also be delivered by medical providers. Instrumental and appraisal support played a more peripheral role as patients identified different types of organizations and exercise classes that provided them with physical and emotional benefits and that was provided by family/friends and medical providers.

Conclusion: We identified all four forms of social support delivered to a group of breast cancer survivors on active AET in formal and informal settings by family/friends, medical providers, and support groups. The social support provided women with educational, physical, and emotional benefits that may play an important role in their continuation of AET.
Comparing characteristics of patients who fill out online surveys before visits with patients who fill out surveys in-clinic with staff assistance at the UCSF breast screening clinic

W Patrick Shibley¹, Nickolas Dreher¹, Laura van 't Veer¹, Irene Acerbi¹, Allison Stover Fiscalini¹, Holly Keane¹, Laura J Esserman¹ and Athena Breast Health Network Investigators and Advocate Partners¹. ¹University of California, San Francisco, San Francisco, CA.

Background: At the UCSF breast screening clinic, intake surveys are sent to women with upcoming mammogram appointments to obtain their demographic data, comorbidities, and assess breast cancer risk (family history, biopsy history). Many patients complete surveys online before their visit. For those who do not, a staff member is present to assist with survey completion on a tablet in-clinic.

Methods: Data was collected from 10,755 patients from December 2012–May 2018. To assess if different survey modalities capture different demographic groups, we analyzed these submissions, comparing responses completed by patients online before visits and in-clinic with assistance.

Results: On average, 48% of invited patients complete a survey. Of respondents 76% completed surveys before visits and 24% completed surveys in-clinic. Both methods captured electronic data that was summarized and presented to clinicians for clinical decision support. Compared to the in-clinic group, a before group patient was more likely to be white, married, and have at least a college education. The before group included a smaller proportion of patients who were Black/African American, Hispanic/Latina, and 65 years or older. Furthermore, a greater proportion of the before group reported 2 or more comorbidities. The before population reported more often having fair or poor health over the preceding 30 days. While these differences were statistically significant, it is important to put some of these results into perspective: while only 24% of survey responses were collected in-clinic, 59.1% of all Black/African American responses and 33.5% of all Hispanic/Latina responses were represented in this group.

</tbody>
</table>

Conclusions/Future Directions: 1) Online surveys are completed more often by traditionally well-represented groups. Offering staff supported electronic surveys in-clinic improves the total yield and diversity of patients who complete surveys. More research is required to see the impact of income levels. 2) We did not anticipate a greater incidence of fair or poor health over the last 30 days or the higher number of patients reporting 2 or more comorbidities in the before group. This could result from the before group having better access to health care, and more familiarity with health surveys, but more detailed study is needed. 3) We will investigate further issues of health care trust, familiarity, and access to adjust our clinic practices. As more studies move surveys entirely online, we need to identify and address factors that prevent patients from completing surveys before appointments. Alternative survey modalities must be made available in accessible ways and integrated into routine clinical
practice.
Barriers to adjuvant radiotherapy treatment for breast cancer in a teaching hospital in Brazil

Carolina M Vieira¹, Angélica Nogueira-Rodrigues¹, Cecília FPM Sousa¹, Lindsay Krush²,³ and Paul E Goss²,³. ¹Federal University of Minas Gerais, Belo Horizonte, Brazil; ²Global Cancer Institute, Boston, MA and ³Massachusetts General Hospital, Boston, MA.

BACKGROUND: Adjuvant treatment of non-metastatic breast cancer (BC) represents an important paradigm of multimodality approach in oncology practice, with an established role for radiotherapy (RT). A delay of adjuvant radiotherapy can lead to poorer results. When chemotherapy (CT) is not indicated, RT should be initiated within 8 weeks after surgery. If CT is administered first, RT should be started within 7 months from surgery, since there is a continuous relation between time to radiotherapy and local recurrence. Brazil's public healthcare system, SUS, faces many challenges caring for cancer patients: inadequate funding, inequitable distribution of resources and services, among others. According to research done by Lins et al, around 458 linear accelerators would be necessary to supply the Brazilian public health demand and end the waiting line for radiation therapy. Currently, our healthcare system has 283 machines, which are responsible for more than 70% of our population. Furthermore, patients lack understanding of treatment windows, which is an additional hurdle.

METHODS: We randomly selected 122 charts of female BC patients submitted to treatment with curative intent from 2003-2017 in Hospital das Clínicas da UFMG, the biggest teaching hospital of the 3rd largest city in Brazil. Primary endpoint was to determine median time from surgery to adjuvant radiotherapy, and second point was to determine median radiotherapy time.

RESULTS: Twenty eight patients were not included in the analysis, 26 due to lack of information in the charts and two for not having received the proposed radiotherapy. Ninety four patients were included: median age was 49 years old (21-90), 21.5% were stage I, 41.9% stage II and 34.4% stage III at diagnosis. Patients received chemotherapy (neo or adjuvant), hormonotherapy, or both, according to oncologists discretion. All patients were submitted to surgery and radiotherapy. Long median times from referral to RT initiation and to radiotherapy completion were identified: 54 days and 97 days, respectively, as well as 7 months from surgery to beginning of RT (1-16) and 9 months from diagnosis to its completion (2-29). Biopsies were performed in 27 different sites and RT in 12.

CONCLUSIONS: This study shows that intervals for completion of adjuvant radiotherapy are well above recommended, mostly due to long delays in initiating radiotherapy. Although in our study all patients were conducted by the same oncology team, the
system is fragmented, making it even more difficult for patients to receive multidisciplinary care and improve prognosis. There is undeniable need for more radiotherapy machines, but since their acquisition depends on costly governmental actions, we need to think about strategies that may allow us to better use the resources already available. We believe that Patient Navigation plays an important role here and we are establishing this program in our institution with Global Cancer Institute support.
Addressing non-adherence for breast cancer screening across ethnicity in southern Arizona

Background In Arizona, female breast cancer has the highest incidence rate and the second highest death rate compared to all other cancers. This ongoing single arm intervention study investigates non-adherence with recommended annual mammography or follow-up breast imaging. Data collected for this study is both retrospective, using the university Electronic Health Record (EHR) system (January 1, 2014 to September 30, 2017), and prospective, implementing a questionnaire during the intervention phase. Potential study participants were identified using EHR and categorized by BI-RADS (Breast Imaging-Reporting and Data System) 0 to 5. With IRB approval from University of Arizona, we designed a questionnaire to measure barriers to adherence and we navigate participants to schedule and attend follow-up appointments. This study's overall specific aims are to increase first time mammography screening by 25% among women in Southern Arizona; increase adherence or repeat screening rate by 20% among women lost to follow-up; establish the framework for a community academic partnership in ethnically diverse areas. Women, age 40 and older who are not compliant with recommended annual mammograms or recommended follow-up screenings after a suspicious finding are eligible to participate in this study. Men and children, as well as women for whom breast imaging is not recommended are excluded from participating in this study. Results Patient's age was summarized by mean ± standard deviation for continuous variables and frequency and the associated percentage for categorical variables. BI-RADS scores were classified into Negative, Benign, Possible Malignancy and Proven Malignancy and compared between ethnic and racial groups using Fisher's exact test. Of 8823 non-compliant woman over nearly 4 years of data, 0.2% are BI-RADS 4 and 5, 2.2% are BI-RADS 3, 96% are BI-RADS 1 and 2, and 0.3% are BI-RADS 0. The mean age is 61.59 years, with 25% reporting as Hispanic, 66% reporting as non-Hispanic women (NHW), and 10% preferring to receive care in Spanish. Initial data shows only .24% with proven malignancies. Further, the data reveals that Hispanics have a slightly higher rate of possible malignancy (.36%) than NHW (.18%); however, NHW show a slightly higher rate of proven malignancy (.27% compared to .18%, respectively). Discussion These data provide valuable information for the direction of this study; in particular, understanding the disparity between Hispanic and NHW malignancies and developing culturally competent interventions and education materials to increase compliance with breast cancer screening recommendations. Further, these data indicate our focus should be on screening compliance for BI-RADS 1 and 2. These data also point to a possible high non-compliance issue. Comparing non-compliance data from other regional clinics will continue to shape this study's direction. The target sample size for this study is 300 participants. We accept a 95% confidence level and a 5% margin of error. Out of 420 recruitment letters mailed, the navigators have reached 152 potential participants by phone and have a 26% study recruitment rate (n=40).
Overall survival of women with breast cancer treated with newly approved targeted drugs in Manitoba: A population based study

Sandeep Devgan¹, Oliver Bucher¹, Marc Geirnaert¹ and Saroj Niraula¹. ¹University of Manitoba and CancerCare Manitoba, Winnipeg, MB, Canada.

Background: Cancer drugs are approved based on the results of clinical trials in selected, rigorously monitored groups of participants. The ultimate goal of new cancer drug approvals is to improve outcomes, preferably overall survival, at population level compared to existing standard of care.

Methods: We conducted a population based study using data from the provincial Manitoba cancer registry, Manitoba Health, and electronic patient records. We collected data on patient demographics, toxicity outcomes, and efficacy outcomes including recurrence and Overall Survival (OS) of patients who were treated with the 10 most frequently used new targeted cancer drugs between January 2005 and December 2017 in Manitoba. Patient demographics were reported using descriptive statistics. Toxicity events were reported in frequency, and Kaplan-Meier curves were used for time-to-event outcomes.

Results: Four breast cancer drugs – Trastuzumab Emtansine (T-DM1), pertuzumab, fulvestrant, and palbociclib qualified for inclusion. During the timeframe, 71 women were treated with T-DM1, 100 with pertuzumab, 102 with Fulvestrant, and 21 with palbociclib. Patient demographics, disease stage, and line of therapy were comparable to those reported in pivotal trials leading to approval of these drugs. Median OS was 15.82 months for T-DM1, 25.34 months for pertuzumab, 14.65 months for fulvestrant, and not assessable for palbociclib – of note, these were consistently about half the median OS duration reported in pivotal trials leading to approval of the respective drugs. [For example, median OS in pivotal trials was 55.6 months for pertuzumab, 29.9 months for fulvestrant, and up to 26.4 months for palbociclib]. Serious toxicities were observed more frequently than reported in the literature – detailed results will be presented.

Conclusion: Despite impressive improvements in outcomes reported in clinical trials leading to approval of new targeted therapies for breast cancer, such agents only yield modest OS at population level which was often worse than even the control groups used in pivotal clinical trials. Given the main aim of new interventions are to improve outcomes at population level, future research should explore causes, and identify solutions to minimize such efficacy-effectiveness gaps. Cautious patient selection, early identification and management of toxicities, and increasing resources available to individual patients may minimize such gaps.
The European initiative in breast cancer (ECIBC) - A program to reduce disparities in cancer care by accreditation of all breast centers in Europe

Robert E Mansel1. JRC Ispra (A Division of DG Sante European Commission), Monmouth, Wales, United Kingdom.

In order to reduce disparities in breast cancer services in Europe, the European Parliament passed resolutions in 2003 and 2006 calling for all women with breast cancer in Europe to be treated by a multidisciplinary team and called on Member States to establish a network of Certified multidisciplinary breast centres.

In the light of these resolutions the European Commission has tasked the Joint Research Centre (JRC) based in Ispra in Italy to set a programme of work from 2014-2020 to update the European Screening Guidelines and produce standards for an accreditation programme for all European Member States.

The methodology is evidence based and the Ibero American Cochrane group has been recruited to examine the evidence for the key questions concerning quality indicators. The whole pathway for breast cancer treatment is being explored from screening to follow up/survivorship, and only indicators supported by evidence are accepted. Indicators have to be relevant, measurable and feasible and currently 50 indicators have been approved using the Delphi system. Many currently used indicators have failed the test of usability due to lack of precision in measurement (eg cosmetic outcomes, margin assessment), or lack of clear definitions (eg counselling,breast care nurse roles, waiting times, MDT working).

A further problem is the different resources applied to breast services across the wide range of economies in European countries (Western v Eastern Europe), which affects the availability of expensive therapies.

The Indicators will form the basis of the accreditation program which will be published in 2019. The detailed evidence for each indicator will be presented in the poster together with the feedback from the 30+ European countries involved.

A pilot of the accreditation program will take place in 2019 to test the feasibility of the audit process in a variety of breast clinic settings.

This project is the most comprehensive attempt to date to produce a robust measurement of breast centers performance based on evidence, and might have global applicability.
Advance directives in Korean cancer patients: Preliminary analysis

Ju Won Kim1 and Kyong Hwa Park1. 1Korea University Anam Hospital, Internal Medicine, Seoul, Korea.

“End-of-life” is a difficult conversational topic in East-Asian culture, even among patients and doctors. In 2016, the “Law on Advance Medical Decisions for End-Stage Patients,” with the so-called “Advance directive (AD),” was enacted in South Korea. Unlike other solid cancers, breast cancer patients have a longer period of survival due to many novel treatments. This study aimed to investigate the acceptance rate of issuing AD and potential barriers to its completion in patients with cancer, including breast cancer (BC).

We conducted a cross-sectional descriptive survey of metastatic or recurrent cancer patients visiting Korea University Anam Hospital oncologic department. The primary end point was the rate of completing AD on doctors’ suggestion. Written interview was conducted to understand the perceptions and factors influencing patients’ decision.

The total sample of 77 patients was analyzed in August, 2018 (29 BC and 48 non-BC patients). The median age was 66.0 years, and duration since diagnosis to suggestion of AD was 56.4 months. The mean follow-up time of physicians who suggested AD was 27.1 months. Of 77 patients, 52 (67.5%) agreed to write AD. Of 29 BC patients, 23 (79.3%) agreed to complete AD, while only 29 of 48 (60.4%) non-BC patients did so.

BC patients who agreed to write AD had older median age, shorter duration since cancer diagnosis, and shorter duration of follow up than those who refused [age 61 vs. 59 yrs p 0.34, diagnosis duration 61.30 vs. 70.63 p 0.40, follow-up period 22.67 vs. 24.13 p 0.64]. Non-BC patients who completed AD had younger age, longer duration since diagnosis, and longer follow-up period [age 68 vs. 71 p 0.67, diagnosis duration 33.1 vs. 33.2 p 0.20, follow-up period 18.0 vs. 16.9 p 0.25]. However, all the differences were statistically insignificant due to small sample size.

The survey showed that patients who agreed to issue AD had relatively high education and were more religious [college graduates 34.6% vs. 16%, respondents with a religion 63.4% vs. 56%]. Of the respondents who completed AD, 42 (80.8%) reported a fare understanding of the concept of hospice palliative care. 21 (40.4%) patients reported understanding AD system “well” or “very well”. Most patients got information about the system from conventional social media like TV and newspaper, followed by their physician [33 (42.9%) and 27 (35.1%)]. Decision on the preparation of advanced life care was mainly by the patients themselves, followed by the spouse and children [38(49.3%), 16(20.1%) and 11(14.3%), respectively].

Reason for writing AD was diverse, including “to leave my own will, not guardian’s” (40.4%), “because my doctors recommended it” (36.5%), “to avoid suffering from meaningless treatment” (26.9%), and “to ease the economic burden on the family” (11.5%). The two major reasons for refusal were “needing more discussion with family” (40.0%) and “lack of understanding of the system” (36%).

In this study, we identified that BC patients are more likely to accept AD than other types of cancer patients. Highly educated and religious patients tended to accept AD without hesitation. Better education and information shared through media and conversation with doctors might improve understanding of the AD system in Korean cancer patients.

Time to treatment discontinuation as a pragmatic endpoint: A U.S. Food and Drug Administration pooled analysis of CDK 4/6 inhibitors

Jennifer J Gao1, Yutao Gong2, Joyce Cheng3, Robert J Schroeder3, Laleh Amiri-Kordestani1, Sean Khoozin1, Paul Kluetz2, Rajeshwari Sridhara3, Richard Pazdur2, Gideon Blumenthal1, Julia A Beaver1 and Tatiana M Prowell1. 1Office of Hematology and Oncology Products, Office of New Drugs, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD; 2Oncology Center of Excellence, Office of Medical Products and Tobacco, U.S. Food and Drug Administration, Silver Spring, MD and 3Office of Biostatistics, Office of Translational Sciences, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD.

**BACKGROUND:** The primary endpoint in many registration trials is progression-free survival (PFS), defined as the time from randomization until objective tumor progression or death. In the clinical setting, however, PFS can be difficult to measure and explain, especially in patient-friendly language. For real-world evidence (RWE) based studies, time to treatment discontinuation (TTD), defined as time from randomization to discontinuation of the investigational study drug, may be a more practical endpoint. We hypothesize TTD will correlate with PFS and analyzed registration trials from recently FDA approved cyclin dependent kinase 4/6 inhibitors (CDKIs) to test this hypothesis. TTD was defined as time from randomization to discontinuation of the CDKI.

**METHODS:** We pooled data from five phase III randomized, controlled, registration trials of CDKIs with an aromatase inhibitor (AI) in the first-line or fulvestrant in the second-line setting. The CDKI discontinuation dates used to calculate TTD were derived from the patient-level datasets. We calculated patient-level correlation between TTD and PFS. We also summarized median TTD and PFS as well as the number of TTD and PFS events.

**RESULTS:** A total of 3017 patients were included in the pooled analysis (n=1899 treated with CDKI, n=1118 with placebo). The median PFS and TTD and the number of events are shown in Table 1. The patient-level Spearman correlation coefficient of TTD and PFS ranged from 0.87-0.95. The trial-level association was approximately $R^2=0.23$.

</tr>
</tbody>
</table>

**CONCLUSION:** Patient-level pooled cross-trial analysis show a relationship between TTD and PFS in registration trials of CDKIs. In all trials, the difference in time between median TTD and median PFS appeared greater in the CDKI arm than the placebo arm. This analysis is limited by the relatively small number of studies included. Further research is needed to determine both whether: 1) TTD can serve as a pragmatic endpoint for analyses of RWE, and 2) is a more meaningful endpoint to patients.
Patient perspectives on HER2+ breast cancer recurrence: Results from an online patient survey

Melissa Jenkins1. 1Breastcancer.org, Ardmore, PA.

Background: The objective of this study was to gather insights from patients with early-stage HER2+ breast cancer regarding fears and knowledge of breast cancer recurrence and approaches to reducing risk of recurrence.

Methods: From Nov. 7-30, 2017, patients with stage I-IIIC HER2+ breast cancer were recruited via postings to Breastcancer.org discussion boards to participate in an online survey comprising 17 questions designed to quantify fears and emotions related to recurrence, identify and characterize knowledge gaps, and understand what patients are willing to tolerate to reduce recurrence risk.

Results: Of 307 respondents, 87% were aged ≥40 years and over half were ≥50 (58%). The majority had completed (48%) or were undergoing (39%) postsurgical treatment. Recurrence was a concern for 93% of patients and was the highest rated concern for 78%; however, most patients (76%) perceived their personal risk of recurrence to be moderate or low. 59% of patients felt they were at least somewhat informed about risk of recurrence; 55% had discussed risk of recurrence with their health care team, with discussions most frequently initiated by the patient (56%) vs the health care team (40%). Oncologists were the primary source of information about risk of recurrence (58%), but patients also frequently sourced information from online content (29%), published research (18%), and Breastcancer.org (15%). Almost all (96%) patients were at least somewhat involved in treatment planning. While 55% of patients would inquire about a new drug if it conferred a 10%-20% reduction in risk of recurrence, 26% required a benefit of ≥50%. For treatments reducing the risk of recurrence, patients were willing to tolerate (in order from most to least willing) hot flashes, fatigue, diarrhea, joint pain, and nausea/vomiting.

Conclusions: While patients with HER2+ breast cancer are highly concerned about recurrence, most feel that their personal risk is moderate. Patients are highly engaged in treatment planning, often initiate discussions about risk of recurrence, and supplement their knowledge with their own research. The threshold to motivate inquiry into a new drug to reduce recurrence risk was <20% for over half of patients. Patients were also frequently willing to tolerate common adverse events.
Patient acceptance of multidisciplinary clinic and an app to communicate with their care team in breast cancer treatment

Maen J Farha
d Medstar Good Samaritan Hospital, Baltimore, MD.

**Background:** Interdisciplinary management improves the care of breast and other cancer treatments. Challenges to such coordinated care have been identified by The National Academy of Medicine (NAM): 1- Poor collaboration among siloed physician 2- Poor patient education and involvement in a shared decision making environment. Multi D cancer conferences are a step in the right direction but true multi D clinics (MDC) with patients contemporaneously engaging their care team are rare. We initiated such clinic at our center and collected feedback information from our patients. We then helped design a HIPAA compliant mobile app, The Accord App™, to allow continued discussion centered around that patient's care and potentially including the patient in the discussion. We are reporting feedback from MDC and any available data on the Accord App™ feedback.

**Methods:** All new breast cancer patients attending our MDC were offered a survey seeking feedback regarding the whole clinic experience, their interaction with team members, clinic environment and the duration of this long consultation. Team members included breast surgery, medical and radiation oncology in addition to other services. Surveys were anonymous and non-obligatory. Surveys asked patients to grade different item on a 3 level scale: 1- Needs improvement 2- Met expectations 3- Exceeded expectations. The length of the consultation (LOC) was rated as: 1- Too short 2- Just right 3- Too long. The Accord App™ was then developed as a HIPAA compliant tool that is being offered to patients and their care teams allowing ongoing discussion of patient care, sharing results and responding to patients’ queries. Initial feedback from provider and patient users is being collected and will be reported.

**Results:** 67 consecutive surveys were prospectively collected and analyzed. The LOC mean score was 2.01. The other scores ranged from 2.49/3 for the physical environment to 2.87/3 for clarity of surgeon provided information. The overall experience was rated as 2.80/3. Feedback from Accord App™ users is being collected.

**Conclusions:** Current collaboration tools including EMRs and Patient Portals have not resolved many of these teamwork and patient engagement issues reported by NAM. The MDC which frequently took over 2 hours was felt to be “just right“ to the vast majority of patients. Our patient mix is quite varied in age groups, levels of literacy, socioeconomic status and ethnicity and we experienced very little variability in that response. Patients rated their experience highly suggesting MDC to be a potentially valuable model for case discussions, cancer care team collaboration and patient engagement in a “shared decision“ environment. Initial feedback from the Accord App™ seems promising and will be reported. More rigorous research into MDCs and mHealth tools such as the Accord App™ is warranted to define and potentially expand their role in breast and other cancer care.
Use of complementary and alternative medicine in cancer patients receiving chemotherapy in Ireland

Soheilali Karmali1,2, Geraldine Markey1, Michael Killian1, Gul Ahmed1, Brian R Bird1,2 and Conleth G Murphy1,2. 1Bon Secours Hospital, Cork, Ireland and 2University College Cork, Cork, Ireland.

Introduction:
The use of complementary and alternative medicine (CAM) in cancer patients has been documented in major cities across USA, Canada, Europe, Nigeria, and Saudi Arabia. These studies suggest that cancer patients on chemotherapy simultaneously use CAMs. In Ireland, there have been two studies in pediatric cancer centers that have documented the use of CAM. To our knowledge, no study has examined the use of CAM in the adult population in Ireland.

Method:
A cross-sectional survey was conducted at a single adult cancer center over a three-week period. The survey was offered to all oncology and hematology patients attending the medical day unit.

Results:
The survey was completed by 81 patients, 51 of them were females (63%). The majority (93.8%) of the patients in our sample were in the age range of 41-80.

47 (58%) of the patients reported using CAM concurrently with conventional chemotherapy. The average cost of CAM was under €20 per month, but five patients (6.2%) spent over €100 per month. The major reasons for taking CAM were to enhance quality of life (23.5%), improve psychological/emotional wellbeing (17.3%), improve immunity (16%), relieve side effects of cancer (9.9%), relieve side effects of treatment (8.6%), and to directly treat/cure cancer (2.5%). Patients using CAM reported their source of information as healthcare professionals (30.9%), family/friends (19.8%), media (13.6%), and CAM practitioners (2.5%). Out of 81 patients, only 27 (33.3%) discussed the use of CAM with a healthcare professional involved in their care, of which 18.2% asked regarding interactions with the conventional therapy, 18.2% asked regarding CAM effectiveness and the type to use, 16.7% asked advice whether to pursue it, and 15.2% asked regarding safety of CAM. From the 26 patients using CAM who did not discuss with HCP the reasons cited were that they were never asked by the HCP (25.9%), did not think it was important to discuss with the HCP (25.9%), and 61.1% did not specify their reason.

Of the 81 patients, 18 consumed herbal products (13.6% green tea, 8.6% flax seed, 3.7% evening primrose, 2.5% soy supplements), 34 used dietary supplements (28.4% vitamins, 12.3% minerals, 3.7% fish oils), and 21 used other CAMs (8.6% massage, 7.4% meditation/mind-body technique, 7.4% acupuncture, 6.2% reflexology, 2.5% reiki).

Conclusion:
The use of CAM in adult cancer patients has not been well documented in Ireland. As demonstrated from the pilot study, adult cancer patients in Ireland do seek out CAMs when simultaneously receiving chemotherapy, highlighting the importance for physicians to explicitly ask all patients regarding their intentions of CAM in order to provide safe and evidence-based options. This cancer center appeared to not have patients pursuing ayurvedic or Chinese medicine. However, similar conclusions cannot be made for other urban centers with more diverse population mixes with differing cultural experiences and attitudes to CAM.
Prioritization of patient reported outcomes by women with metastatic breast cancer

Sarah S Mougalian¹, Jenerius A Aminawung¹, Carolyn Presley², Maureen E Canavan¹, Margaret L Holland², Xin Hu⁴ and Cary P Gross¹. ¹Yale School of Medicine, New Haven, CT; ²Ohio State University School of Medicine, Columbus, OH; ³Yale School of Nursing, New Haven, CT and ⁴Yale School of Public Health, New Haven, CT.

Introduction: An emphasis on patient-centered care has led to a growing interest in collecting patient-reported outcomes (PROs) in the setting of cancer care. Routine collection of actionable PROs has been shown to improve patient satisfaction with care and even prolong survival. However, completion rates of PROs outside of the research setting are low, which may be due to an incomplete understanding of the outcomes patients value most. Prior work has focused primarily on symptom burden, but patients are also affected by disease and treatment across multiple domains (e.g. physical, psychological, social, and financial). To address this knowledge gap, we conducted a qualitative study among women with metastatic breast cancer (MBC) to identify the optimal patient-centered approach to collecting PRO data.

Methods: We conducted 1-on-1 interviews with patients who had started a treatment regimen for MBC within the past 6 weeks at the Breast Center at Smilow Cancer Hospital of Yale New Haven Hospital to determine which PROs were most personally relevant. We assessed heterogeneity across patients in their prioritization. Patients were asked which of a list of six PRO domains they would like their provider to have information about and then ranked the domains by order of importance (from most to least important). The following domains were created from the NCCN Distress Thermometer: physical well-being, emotional well-being, treatment burden, functional status, financial concerns, and social well-being. For each ranked domain, patients were asked to rank items within the domain using a card sorting exercise where the number of items ranged from 5 to 15. Patients were then asked where and how often they preferred to report PROs.

Results: Ten women with MBC completed the card sorting exercise: mean age was 58 years (+/- 12), 7 were white, 2 African American and 1 Asian; 1 identified as Hispanic. After 10 interviews, it was apparent that no single set of domain rankings was common across patients. Patient prioritization of PRO domains was unique and varied. Selection and prioritization of PRO domains and items within each domain were unique and varied. Five women reported “physical well-being” as the most important domain; treatment burden and emotional well-being were also selected as most important or ranked as highly important. Participants preferred reporting MBC PROs while in the waiting room for all domains except emotional well-being (from home was the preference). However, participants were willing to complete PRO assessment in the waiting room for about ten minutes and at home for twenty minutes.

Conclusion: Substantial variation exists in how women with MBC rate the importance of specific PRO domains and items within each domain. Importantly, “physical symptoms” was not the top concern for half of the interviewed patients. This is an important finding, given that previous published studies of patient-reported outcomes have focused on one domain, such as symptoms and side effects or the financial burden of treatment. Our findings support the development of multi-dimensional tools for the collection of PROs. Although toxicity and physical symptoms are of utmost concern, clinicians should not neglect other dimensions of quality of life in women with MBC.
Accuracy of psychosocial assessments in an online surgical decision aid developed for early breast cancer patients with resource and educational constraints

Shalaka Joshi¹, Lakshmi Ramarajan², Naresh Ramarajan³, Gitika Srivastava³, Farzana Begum³, Ojas Deshpande¹, Ashutosh Tondare¹, Nita Nair¹, Vani Parmar¹, Sudeep Gupta¹ and Rajendra A Badwe¹. ¹Breast Disease Management Group, Tata Memorial Centre, Mumbai, Maharashtra, India; ²Harvard Business School, Boston, MA and ³Navya Network, Cambridge, MA.

Background: Women with early breast cancer routinely face a choice between breast conservation therapy and mastectomy, and assume agency through shared decision making. However, for women with lower socioeconomic power or education, barriers such as access to understandable information, involvement of family in decision making, and a decreased sense of autonomy inhibits this agency. To better empower this population, a simple to understand, online, self-administered, conjoint analysis based decision aid called “Navya Patient Preference Tool” (PPT) is developed to be used outside the physician encounter. PPT is unique in its incorporation of several psychological scales that assess potential confounders of participation in shared decision making.

Methodology: This is a pre-planned analysis of the reliability and validity of the psychological scales used in all three arms of an IRB approved randomized controlled trial to assess PPT. Women with operable node negative breast cancer eligible for BCT or MRM at one of Asia's largest academic tertiary cancer centers were eligible. PPT trial consists of an initial conjoint analysis questionnaire analyzing implicit preferences for breast conservation given to the intervention arms. The following psychological scales were given to all patients regardless of randomization: Autonomy Preference Index (API), Traditional-Egalitarian Gender Roles (TEGR), Caregiving Role, Brief Resiliency Scale (BRS), Appearances Scale, and Decisional Conflict Scale (DCS). Cronbach's alpha as a measure of internal reliability for all scales were high, with Cronbach's alpha above 0.7: API 0.74, TEGR 0.78, Caregiving 0.7, BRS 0.7, Appearance 0.84. DCS was highly reliable at 0.91, and is the primary outcome measure for the RCT. Correlations in the dataset met those expected in real world data, suggesting external validity. For e.g., education was inversely correlated with traditional gender roles on TEGR (R -0.4, p <0.01), and positively correlated with resilience on BRS (R 0.228, p <0.05). Individual scale items that are unrealistic were not chosen by any of the 102 respondents (e.g., My doctor should not participate in my medical decisions), substantiating nuanced reading. 85% of patients “Strongly Agreed” on a 1-5 Likert scale that “The survey questions were easy to understand” (mean score 1.18/5. SD 0.4).

Conclusions: Women with limited education and low socioeconomic status complete the online, self administered PPT outside of a physician encounter, with high internal reliability and external validity. Decision Aids such as Navya PPT, which account for psychosocial confounders of agency, have the potential to benefit women otherwise marginalized from shared decision making.
Psychosocial needs identified by the healthcare team in Latino breast cancer patients

Oscar Galindo-Vázquez\(^1\), Enrique Baragalló-Rocha\(^1\), Paula Cabrera-Galeana\(^2\), Rosario Costas-Muñiz\(^1\), Abel Lerma\(^1\) and Nereida Esparza-Arias\(^1\). \(^1\)National Cancer Institute of Mexico, Mexico, Mexico and \(^2\)Memorial Sloan Kettering Cancer Center, New York, NY.

Psychological consequences in patients with BC. According to the literature, it is pertinent to classify the consequences in: a) physical, (which will be divided according to the type of treatment); b) sexual; c) psychological (that contemplate cognitive and emotional aspects); and d) social (including work or professional conditions, family and couple life).

Methodology. A cross-sectional design was used. A questionnaire was sent in electronic format to a group of 3,000 health professionals from different disciplines throughout Mexico who care for breast cancer patients in public and private health services. 256 health professionals responded (46 ± 11.4) years, (55% female). The highest academic level achieved was subspecialty (46%), specialty (22%), master’s degree (14%), undergraduate (11%) and doctorate (7%).

Instrument: The survey consists of 34 items in sections that assess psychosocial aspects, physical symptoms, disability, intensity of symptoms, psychosocial needs of patients, effects on the medical treatment and available mental health services.

Results. Health professionals dedicate (31.6 ± 11.4) hours per week to see patients and attend (46.4 ± 42.2) patients per week. They consider that the presence of emotional problems in patients (69.3% average) can affect the quality of life (66%), adherence to treatment (42%), severity of side effects (40%), mortality (33%), and cause communication problems with family and healthcare team (33 to 39%). Additionally, 64% of patients with cancer have depression and 71% anxiety. Mental health professionals see, in average 61% of patients with cancer problems.

Only 8% of health professionals use a validated instrument to detect emotional distress and 72% do so through questions. Up to 20% of them wait for patients to tell them directly at outpatient clinics or in hospitalization. The main physical symptoms reported that professionals identify in cancer patients are: fatigue (31%), appetite problems (23%), pain (20%), sleep (19%) and nausea (18%).

The main needs to be met in patients with cancer are: information about their diagnosis (66%), emotional support (30%), information about treatment (34%), or prognosis (27%). When they identify mental health problems, health professionals refer their patients to psycho-oncology (55%), psychiatry (37%) or social work (21%). The most frequent disciplines of health professionals were: surgical oncology (24%), oncological gynecology (9%) and only 3% were psychologists. 32% of healthcare professionals had 20 or more years since graduation, or were between 10 and 19 years of graduation (31%), while 38% had 9 or less years since graduation. The main setting was general hospital (33%) or oncological hospital or clinic (32%).

Conclusions. Healthcare professionals who treat patients with BC have a high level of preparedness; However, a third of them had more than 20 years since graduation, which suggests specific needs for updating, especially in the identification of psychosocial issues and timely referral for emotional management. On the other hand, there is a very low prevalence of psychologists specializing in psycho-oncology, who receive the greatest burden of internal referrals from health professionals.
Integration of primary care practitioners in a breast multidisciplinary team meeting- A pilot study

Meron E Pitcher¹, Ilana Hornung¹ and Priya Rangarajan¹. ¹Western Health, Melbourne, Australia.

Primary care practitioners are key to integrated patient care, as they often have an established relationship with patient and family, with knowledge of comorbidities and psychosocial factors. They can encourage compliance with cancer treatments and manage transition from acute care through survivorship.

Communication with primary care however has often been unsatisfactory, with information not helpful to that practitioner or not provided in a timely manner.

We recruited a general practitioner (GP) to attend the weekly breast cancer multidisciplinary meeting, with a responsibility to make contact with the primary care practitioner of patients presented prior to the meeting, so that relevant information from a primary care perspective could be taken into consideration for team deliberations. This also meant that the primary doctor was aware the patient was being discussed. Recommendations were fed back to that doctor after the meeting so that information was timely, and, being given by a peer, more useful.

The GP attended 12 consecutive MDTs where 105 patients were discussed. In 55% contact was able to be made with the patient's GP prior to the meeting. This was perceived as not usually changing management plans, but reinforced known medical and social concerns. Feedback to the patients GP was regarded favourably, with reported greater confidence in managing the patient, particularly those with complex needs, as well as improving hospital to community communication in general.

This pilot has shown that it is feasible to include primary care practitioners in a multidisciplinary meeting and improve interdisciplinary communication.
The use of 18F-FDG PET/CT as an initial staging procedure for stage II-III breast cancer reduces false positives, costs, and time to treatment: A multicenter value analysis in the I-SPY2 trial

Colby J Hyland¹, Flora Varghese¹, Christina Yau¹, Heather Beckwith², Katia Khoury³, William Varnado⁴, Gillian Hirst¹, Jo Chien¹, Douglas Yee⁵, Claudine Isaacs³, Andres Forero-Torres⁴, Laura Esserman¹, Michelle Melisko¹ and I-SPY2 Consortium⁵. ¹University of California, San Francisco, San Francisco, CA; ²University of Minnesota, Minneapolis, MN; ³Georgetown University, Washington, DC; ⁴University of Alabama at Birmingham, Birmingham, AL and ⁵Quantum Leap Healthcare Collaborative, San Francisco, CA.

Introduction: Diagnostic metastatic staging imaging (SI) for asymptomatic stage I-II patients (pts) is not routinely recommended, but is warranted in stage II-III pts with high risk biological subtypes, where previous trials have shown up to a 15% rate of de novo metastatic disease. NCCN guidelines endorse CT CAP and bone scan (STD) for stage III pts, but not PET/CT, and PET/CT is not covered in most parts of the country. We present data on the performance and value of PET/CT.

Methods: Data were available for 799 high risk clinical stage II-III pts screened for I-SPY2 at UCSF, Uminn, UAB, and Georgetown. Of these, 564 pts ranging in age from 25-81 (median = 48) had complete records that were retrospectively reviewed for SI and potential false positives (FP), defined as incidental findings on SI proven benign by subsequent workup. Economic evaluation was conducted from the payer perspective using the mean national 2018 Medicare Physician Fee Schedule and representative costs from the UCSF billing department. The incremental cost effectiveness ratio (ICER) measured the cost of using PET/CT per percent patient (pt) who avoided a FP.

Results: The rate of de novo metastatic disease was 4.8% (38/799), range 3.6-6.4%. Of the 564 pts with complete records, diagnostic SI varied significantly among the four sites (p < 0.0001). STD was used for most pts at UAB (92.8%, 141/152) and Georgetown (85.7%, 54/63), while PET/CT was used for most pts at UCSF (86.6%, 226/261) and Uminn (63.6%, 56/88). Chest X-ray was used for 29.5% (26/88) at Uminn. There were significantly more pts with FP in the group that received STD (22.1%, 51/231) vs. PET/CT (11.1%, 33/298) (p < 0.05). Mean time between incidental finding on SI to determination of FP was 10.8 days. When controlling for institution, mean time from cancer diagnosis to initiation of neoadjuvant chemotherapy was significantly different between STD (44.3 days) and PET/CT (37.5 days) groups (p < 0.05). When aggregating the four sites using mean costs from the 2018 Medicare Physician Fee Schedule, the mean cost/pt was $1132 for STD vs. $1477 for PET/CT. The mean increase in price from baseline SI costs due to FP workup was $216 (23.6%) for STD vs. $65 (4.6%) for PET/CT. The ICER was $31 per percent pt who avoided a FP. When analyzing UCSF pts alone using representative reimbursements from Medicare, the mean cost/pt was $1236 for STD vs. $1081 for PET/CT; using representative reimbursements from Anthem Blue Cross, the mean cost/pt was $3080 for STD vs. $1662 for PET/CT. The ICERs were -$10 and -$95 per percent pt who avoided a FP, respectively.

Conclusion: As compared to STD metastatic staging workup, PET/CT added value by decreasing FP two-fold. This reduced direct costs of FP workup procedures that took a mean time of 10.8 days to resolve. PET/CT also accelerated treatment start. Reducing the chance of FP workup for metastatic disease is of enormous value to pts. Our data establish the value of PET/CT for staging in our high risk clinical stage II-III trial population and highlight the need for alignment between hospital pricing strategies and payer coverage policies in order to deliver high value care to pts.
Evaluating the cost of endocrine therapy vs. radiation therapy alone for low risk hormone positive early stage breast cancer in elderly patients

Matthew C Ward¹, Frank Vicini², Manjeet Chadha³, Lori Pierce⁴, Abram Recht⁵, James Hayman⁴, Nikhil Thaker⁶, Atif Khan⁷, Martin Keisch⁸ and Chirag Shah⁹. ¹Levine Cancer Institute, Charlotte, NC; ²21st Century Oncology, Farmington Hills, MI; ³Mt Sinai Hospital, New York, NY; ⁴University of Michigan, Ann Arbor, MI; ⁵Beth Israel Deaconess Medical Center, Boston, MA; ⁶Arizona Oncology, Tucson, AZ; ⁷Memorial Sloan Kettering Cancer Center, New York, NY; ⁸Cancer HealthCare Associates, Miami, FL and ⁹Cleveland Clinic, Cleveland, OH.

**Objective:** Elderly patients with low-risk hormone-positive breast cancer are at risk of over treatment. Avoidance of radiation therapy (RT) in favor of endocrine therapy alone was first heralded as the optimal conservative strategy due to logistical simplicity, low acute sequelae and a reduction of contralateral cancers not seen with RT. However, long-term use of aromatase inhibitors (AI) is not without costs and morbidity, often leading to low compliance and notable late effects. We therefore performed a cost-effectiveness analysis to compare the outcomes and costs between AI for five years without RT versus hypofractionated RT alone without endocrine therapy.

**Materials and Methods:** Using data from available phase III trials and meta-analyses, we constructed a patient-level microsimulation Markov decision model to replicate the comparative outcomes between the strategies above from the societal perspective among 200,000 simulated patients. Five years of anastrozole was compared to a 15-fraction hypofractionated whole breast RT course without boost in a cohort of patients with low-risk disease as defined by CALGB 9343 entry criteria. Noncompliance with AI was modeled from recent population-based data. Relative effectiveness on ipsilateral breast tumor recurrence and contralateral breast cancers were based off the NSABP B-21 trial, adjusted to match the modern outcomes demonstrated in CALGB 9343 and PRIME II with further adjustment for AI over tamoxifen (ATAC, EBCTCG meta-analysis). Indirect costs of travel were accounted for, as were the costs of common and serious side-effects from RT (dermatitis, fibrosis, second malignancy, heart disease) and AI (arthralgia, hot flashes, osteopenia, fracture, thrombosis). A 1-year cycle time and lifetime horizon were used, with all costs adjusted to 2018 US dollars and extracted primarily from Medicare reimbursement data. The primary measure of efficacy was the quality-adjusted life-year (QALY) with age-adjusted utilities extracted from the literature. Half-cycle correction and a 3% discount rate were applied. Probabilistic sensitivity analysis was used to vary all parameters simultaneously.

**Results:** On average, RT was approximately $3,981 more expensive than endocrine therapy over the lifetime horizon. Under a number of assumptions, RT appeared similar in long-term effectiveness to AI therapy, with a difference of less than 0.03 quality-adjusted life years. Given the low value of the denominator in the incremental cost-effectiveness ratio (ICER), RT did not meet the formally defined $100,000/QALY threshold. On one-way sensitivity analysis, the ICER was particularly sensitive to the incidence and impact of salvage strategies for recurrence, treatment of contralateral breast cancers, cardiac events and fracture rates.

**Conclusions:** Modeling with the available evidence suggests it is likely that quality-of-life after RT-alone is nearly identical to an AI-alone strategy but associated with a small increase in cost. These results suggest select patients at risk of noncompliance can safely be treated with RT-alone rather than AI alone. Given the relative pros and cons of each strategy, RT-alone should be considered for select elderly low-risk breast patients.
Imaging is not indicated in staging of asymptomatic patients with early breast cancer – Are we following current recommendations?

Ana I Velazquez¹, Nina T Nguyen¹, Carlos Rodriguez-Bonilla¹ and Theresa Shao¹. ¹Icahn School of Medicine at Mount Sinai Beth Israel, New York, NY.

Breast cancer is the most common malignancy in women with estimated care costs of $20.50 billion/year by 2020. In 2012, ASCO released the Choosing Wisely Initiative which recommended against the use of routine staging imaging in patients with newly diagnosed early stage breast cancer. We examined physician's adherence rate and factors associated with non-adherence to current guidelines in patients with early stage breast cancer treated within a large urban health care system.

We identified all women with stage I-II breast cancer diagnosed between January 1, 2014 and December 31, 2015 from the Cancer Registry of the Mount Sinai Health System. Patients with history of prior malignancy or symptom-triggered imaging were excluded. Demographic, clinical and treatment related factors were collected. Medical records were reviewed to identify patients who had routine staging scans. Data of initial and follow-up imaging over 1-year period were collected. Odds ratios (ORs) and 95% confidence intervals (CIs) were estimated from logistic regression models.

Among 917 breast cancer patients, the median age at diagnosis was 59 years (range 26-98). One hundred seventy one patients (18.6%) had routine staging imaging with a mean number of initial scans of 1.48. Eighty-two patients (48%) had at least 1 subsequent scan in the 1-year follow up (range 1-4 scans/year). PET/CT was the most frequent modality (49%), followed by CT scan (33%). The medical oncologist was the ordering provider in 50.3% of the cases and surgical oncologist in 43.2%. Routine staging scans identified no cases of metastatic disease. False-positive findings were identified in 49.7% and incidental findings in 9.3% of cases. Total cost of imaging in this group was $3990/patient. Young age (<50 years old), tumor size >2cm, positive lymph nodes, and triple negative disease were associated with presence of routine staging scans on univariate and multivariate analysis (Table 1).

Our study highlights the prevalence of unnecessary staging scans in up to 18.6% of patients with early stage I-II breast cancer. Routine imaging resulted in increased radiation exposure, multiple subsequent imaging, and increased economical burden particularly for those of young age, T2 tumors, positive lymph nodes, and triple negative disease. Further educational efforts are needed to avoid unnecessary scans in patients with early stage breast cancer and improve high-value practices among medical and surgical oncologists.

Oncotype DX cost effectiveness to a Brazilian public hospital

Cesar Cabello¹, Rodrigo Natal de Andrade¹, Thiago F Cabello¹, Sandra Teixeira¹, Larissa Saito da Costa¹ and Susana Ramalho¹.
¹State University of Campinas (UNICAMP), Campinas, Sao Paulo, Brazil.

Introduction: The Oncotype DX was associated to 14% of adjuvant chemotherapy administration to Hormonal Receptor positive (HR+) and HER2 negative, T1N0 or T2N0 breast cancer patients at Tailor X trial recently published (RS>25)

Objective: To describe the adjuvant chemotherapy administration to a Brazilian public hospital for HR+ HER2 negative, T1N0 or T2N0 breast cancer patients. And the estimate the cost effectivity of Oncotype DX in our low income scenery.

Materials and Methods: This retrospective cross-sectional study was conducted at the Oncology Division of the Women's Hospital - CAISM of the State University of Campinas (UNICAMP), Brazil. All patient data were found from the hospital records from 2007 to 2009. It was included T1N0 and T2N0 HR+/HER2 negative breast cancer patients. Patients submitted to neoadjuvant treatment were excluded.

We calculate the final cost of different types of chemotherapy used and the potential impact to oncotype DX introduction in this scenery.

Results: It was found 109 patients records. 66% (72/109) had received adjuvant chemotherapy. 35% (38/109) had AC (X6), 29% (32/109) had CMF (X6) and 2% (2/109) had AC-T (X4). The total cost for chemotherapy scheme were; AC (X6) US$ 346,9; CMF (X6), US$300,6; ACT (X4), US$395,9. The total cost of chemotherapy was US$ 23.596,83 to 72 patients. If we consider 14% (15/109) of adjuvant chemotherapy associate to a Oncotype DX use (Tailor X RS>25), It would reduce adjuvant chemotherapy administration to 15 patients. The chemotherapy cost would be US$ 4588,27. In our scenery, It could save US$ 19.008,56.

Nevertheless, the Oncotype Dx cost to Brasil is US$ 3.200,00 for each test. To 109 patients the total cost would be (109 X US$ 3.200,00) US$ 348.800,00. Therefore, the total cost for Oncotype DX program plus adjuvant chemotherapy for our patients would be US$ 348.800,00 + US$ 4.588,27 = US$ 353.388,27. While in the real situation we had spent US$ 23.596,83. The total estimate cost would be 15 times more.

Conclusion: At the moment, because of the assay high cost and the low cost of the adjuvant chemotherapy to HR+, HER2 negative T1N0 and T2N0, It would be difficult to consider Oncotype DX cost-effective to Brazilian public heath system. Even considering many advantages to spare chemotherapy to this population.
Long-term quality of life after four common surgical treatment pathways for breast cancer and the effect of complications

Casimir AE Kouwenberg¹,⁵, Kelly M Ligt²,³, Hinne A Rakhorst⁴, Danielle Leeuw⁴, Sabine Siesling²,³, Jan J Buschbach⁴, Leonieke W Kranenburg⁵ and Marc AM Mureau¹. ¹Erasmus MC Cancer Institute, University Medical Centre Rotterdam, Rotterdam, Netherlands; ²Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands; ³Faculty of Behavioural, Management and Social Sciences, Technical Medical Centre, University of Twente, Enschede, Netherlands; ⁴Hospital Group Twente (ZGT), Hengelo, Netherlands and ⁵Section Medical Psychology and Psychotherapy, Rotterdam, Netherlands.

Background: Comparing the quality of life (QoL) for all common breast cancer surgery options could support decision-making. However, current evidence generally consists of non-preference-based outcomes for sub-comparisons of options which are unsuitable for the calculation of Quality Adjusted Life Years (QALYs), the preferred outcome in health economics. The preference-based EQ-5D-5L is specifically designed to provide the Q in QALY and could facilitate a (health-care) wide comparison of breast cancer surgery options. This study gives an overview of both non-preference and preference-based QoL after four common surgical breast cancer treatment pathways.

Method: Breast cancer patients from a large multicenter observational cohort in the Netherlands were invited for participation in an online survey. QoL was obtained by the EQ-5D-5L, EORTC-QLQ-C30/-BR23 and Breast-Q questionnaires. Patient cohorts based on surgical procedure (breast-conserving surgery (BCS), mastectomy (MAS), autologous breast reconstruction (A-BR) and implant-based breast reconstruction (I-BR) were compared after propensity-weighted adjustment of pretreatment differences.

Results: Of all invited patients, 1871 responded, respectively patients treated with BCS (n=615), MAS (n=507), A-BR (n=330), and I-BR (n=419). Table 1 shows QoL outcomes without overlapping 95% CI. Patients reported complications in 47% of the A-BR, 32% of the I-BR, 18% BCS and 22% of the MAS groups. QoL outcomes differed statistically significantly between patients with and without complications for all groups, except the I-BR group.

</table>

Mean values of the respective outcome scale after propensity score weighting and are derived from an estimator of the average treatment effect on the population. Values in the same row not sharing the same subscript do not show overlapping 95% Confidence Intervals in a pairwise comparison.

**Discussion:** Preference-based QoL outcomes are an essential input for cost-effectiveness analyses, used to justify the use of care in a society progressively confronted with increasing health care expenses. The results from this large multicenter cohort study contribute substantially to the current knowledge in the field of breast cancer reconstructive surgery.
Potential Medicare beneficiary out-of-pocket cost reductions through use of biosimilar filgrastim-sndz over reference filgrastim among breast cancer patients: A simulation model analysis

Gary Puckrein¹, Liou Xu¹, Alan Ryan², Kim Campbell² and Sanjeev Balu². ¹National Minority Quality Forum, Washington, DC and ²Sandoz Inc., Princeton.

Rationale & Objective: Granulocyte colony-stimulating factors (G-CSFs) are utilized to decrease the incidence of febrile neutropenia (FN) in patients with cancers undergoing chemotherapy treatments. In 2015 biosimilar filgrastim-sndz was the first biosimilar to be approved and launched in the US market. Limited data exists in ascertaining the impact of biosimilars on patient out-of-pocket (OOP) expenditures. The objective of this simulation model was to estimate potential OOP cost savings through use of filgrastim-sndz over reference filgrastim from a Medicare breast cancer patient perspective.

Methods: An Excel simulation analysis was conducted among breast cancer patients treated with biosimilar filgrastim-sndz or the branded reference filgrastim (identified through HCPCS codes). Data from the 2016 Medicare Limited Data Set (5% sample of the carrier file) was used to populate the model. The payment calculation worksheet within the Medicare carrier file was used to calculate the average Medicare payment to the provider and the average beneficiary OOP responsibility per claim of either filgrastim-sndz or reference filgrastim. The average OOP reduction per claim for a filgrastim-sndz beneficiary relative to a reference filgrastim beneficiary was multiplied to a hypothetical FN prevalent population of 100,000 beneficiaries (average of 10 claims per beneficiary) to estimate the potential OOP savings.

Results: Data for 616 filgrastim-sndz and 1,064 reference filgrastim claims were used to populate the model. The average Medicare allowed charge amount per claim for a filgrastim-sndz beneficiary was $362.8 versus $406.9 for a reference filgrastim beneficiary, while corresponding average Medicare payments to the provider were $284.1 and $316.9, respectively. On an average, OOP responsibility for a filgrastim-sndz beneficiary was lower compared to a reference filgrastim beneficiary ($72.9 versus $82.5) leading to a cost saving per claim of $9.60. When extrapolated to 100,000 beneficiaries (1,000,000 claims), the overall cost saving was projected to be around $9.6 million.

Conclusions: Our simulation model estimated a potential OOP Medicare breast cancer beneficiary saving of around $9.6 million, based on a hypothetical population of 100,000 FN beneficiaries, with the use of biosimilar filgrastim-sndz over reference filgrastim. Further real-world analyses are required to evaluate the true cost saving potential from a breast cancer patient perspective with the use of biosimilars over reference biologics.
Breast surgery – Is routine ‘group & save’ required? A quality improvement project

Rajaram Burrah¹, Wayne Chicken¹ and Sharlini Sathananthan¹. ¹Basildon and Thurrock University Hospitals, Basildon, Essex, United Kingdom.

Introduction
Breast surgery, especially for malignant disease, is not associated with significant blood loss and therefore rarely requires blood transfusions. Pre-operative protocols in our hospital and in most other centers routinely require a blood group screening process (group and save) for elective breast cancer surgery. The process of group and save (G&S) in our hospital requires two blood samples to be drawn with at least 30 minute interval in-between. It takes at least 40 minutes for the samples to get processed and the cost for each test is £2.12. The test is valid for a period of 5 days after which time it needs to be repeated. This process in busy hospitals is clearly time consuming, results in delays and is inconvenient for patients and medical staff.

The aim of this study was to ascertain the number G&S performed and rate of post-operative blood transfusion for patients undergoing surgery for malignant breast disease. This was to establish if mandatory pre-operative G&S is necessary in all cases, and if the number of tests performed can be reduced. The second part of the study was to analyze the outcome after implementation of changes to reduce the number of G&S tests.

Method
Retrospective review of patient records who had surgeries for malignant breast disease from December 2015 to November 2016. Exclusion criteria included benign disease, flap reconstruction and breast surgery combined with another major procedure.

Following the initial analysis, it was proposed that only the operating surgeon will request the test and that it will not be routinely requested by the pre-op assessment team. A re-audit was done prospectively to study the outcome of change in practice and close the audit loop.

Results
151 cases were eligible for review. 97.35% (147 patients) had G&S, and the post-operative transfusion rate was 1.32% (2 patients). Following a change in protocol a significant fall in the testing (97.35% to 35.5%) was seen and there were no post-operative blood transfusions in this period.

Conclusion
This simple yet important audit showed that routine G&S did not contribute to the patient management, increased cost of treatment, caused patient inconvenience and consumed hospital personal time. The changes we implemented significantly reduced the frequency of this test and was cost effective to the trust. This study has now been converted into a Quality Improvement Project and through this we will continue to improve the results further. This project has also stimulated an interest in the General Surgery department, and other units are now considering changing their practice based on our results.
Economic Impact of MammaPrint (70-gene signature) in a clinical high risk population: A 10yr Markov model, 6,000-patient retrospective analysis of US claim data

Lisa E Blumencranz¹, Anan Høst-Ragab¹, Valesca P Retèl², Henry Garlich³, Colin Hwang⁴, Sari Neijenhuis¹, Mehran Habibi⁵ and William Audeh¹. ¹Agendia Inc, Irvine, CA; ²Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; ³BlueCross Blue Shield California, Rancho Cordova, CA; ⁴Blue Cross Blue Shield, San Francisco, CA and ⁵Johns Hopkins Breast Center at Bayview, Baltimore, MD.

Background: MINDACT provided evidence that MammaPrint (MP) can identify patients (pts) with early-stage breast cancer (ESBC) who can safely forego adjuvant chemotherapy (CT). As a result, 46% of clinicopathologically high-risk pts were spared from unnecessary CT toxicities. This study investigates direct and indirect costs for pts and payers during ESBC treatment regimens. The study objective was to quantify average cost of care and savings in a clinical high-risk group where the value of CT is unclear, and MP demonstrates economic and clinical impact. Methods: Risk assessment was based on 6,000 MP tests performed on BCBS members (2016-17). CT claims were retrospectively analyzed utilizing a Blue Cross Blue Shield (BCBS) member database (January-December 2016). Case data was restricted to HR+HER2- ESBC and filtered by authorization for the MP test. All CT claims were including, but not limited to standard of care (SOC) systemic drugs such as cyclophosphamide, docetaxel, paclitaxel and doxorubicin. HCPCS codes were utilized to filter member CT claims. Exclusion criteria: <3 SOC CT claims and previous history of BC. A hybrid decision tree-Markov model was used to estimate cost effectiveness of MP compared to modified Adjuvant Online (mAOL) from a US healthcare payer perspective over a 10yr timeframe. Overall, distant metastasis free survival, and test-utility scores were collected from MINDACT for HR+HER2- pts, and costs derived from the BCBS registry and literature (2016 US dollars). Two scenarios were modelled (1) all women classified as high-risk received CT plus endocrine therapy (ET) while low-risk pts received ET; (2) MP guided treatment was modelled based on the IMPACT study (91% MP Low Risk pts received ET and 83% MP High Risk pts received CT). Outcome measures were quality-adjusted life years (QALYs), and incremental cost-effectiveness ratios (ICERs).

Results: The majority, 3,540 (59.0%) pts were Low Risk or could safely forgo CT; 2,460 (41.0%) were High Risk. The primary driver for cost differences was whether all services were performed in a physician office ($4.6M) or an outpatient setting ($2M). Including provider settings (inpatient, outpatient, emergency), SOC CT regimens and related services the final average amount authorized was $39,675 per patient. In the first scenario, MP guided treatment was associated with a 0.06 QALY gain (0.05 in scenario 2) compared to mAOL. For cost savings and QALY gain MP was dominant over mAOL in both scenarios. Budget impact analysis estimated cost savings of 88.2- 96.6 million dollars based on BCBS registry data. Given the new cases of BC that are expected to be diagnosed in women in the U.S. annually, pts covered in this population by BCBS (~30%) and MP eligible cohort (~36K pts), projected cost savings are estimated at 529.2-644.3 million dollars per annum for the health insurer.

Conclusions: CT was associated with significant annual costs from both patient and payer perspectives. As demonstrated in MINDACT, less treatment for some pts is optimal without risk to safety or survival. These findings suggest that MP is cost effective and provides substantial value by sparing pts from toxicities, both therapeutic and financial.
Impact of oncotype dx genetic signature used in early breast cancer. Clinical and economic analysis of a 110 patient cohort treated in the Catalan Oncologic Institute (ICO), Spain

Marta Ferrer¹, Joan Dorcas², Vanesa Quiroga³, Mireia Margelí³, Sonia del Barco², Agostina Stradella¹, Anna Petit⁴, Catalina Falo¹, Gemma Viñas¹, Margarita Romeo³, Rafael Villanueva¹, Beatriz Cirauqui³, Silvia Vázquez¹, Adela Fernández¹, Sabela Recalde¹, Andrea Vethencourt¹, Teresa Soler⁴, Xavier Pérez-Martín⁵ and Miguel Gil-Gil¹. ¹Hospital Duran I Reynals. ICO Hospitalet, L'Hospitalet de Llobregat, Barcelona, Spain; ²Hospital Josep Trueta. ICO Girona, Girona, Spain; ³Hospital Germans Trias I Pujol. ICO Badalona, Badalona, Barcelona, Spain; ⁴Hospital de Bellvitge. Hospitalet de Llobregat, L'Hospitalet de Llobregat, Barcelona, Spain and ⁵Statistical. Clinical Research Unit. Hospital Duran i Reynals. ICO Hospitalet, L'Hospitalet de Llobregat, Barcelona, Spain.

Introduction
Benefit from adjuvant chemotherapy (CT) is doubtful in a high percentage of patients with early breast cancer. The 21-gene recurrence-score (RS) assay (Oncotype DX, Genomic Health) is one gene-expression assay that provides prognostic and predictive information in hormone-receptor (RH) positive breast cancer. The results of the TAILORx study have confirmed that the majority of patients with tumors RH + and HER2 negative can avoid CT without increasing their risk of relapse. From 2012 to 2015 we used Mammaprint (MMP), in our institution and 60% of cases could avoid CT (communicated in SABCS 2015). Since 2017 we use RS for this purpose.

Primary Objective
To analyze the impact of using RS to change the indication of adjuvant CT.

Secondary Objectives
To analyze the association between different clinical pathological factors and the RS value, and calculate the difference between the cost of all RS test and the cost in direct expense of the treatment with CT of all patients who could avoid it thanks to the RS

Material and methods
We analyzed all RS test performed in the three ICO centers during 2017. We sent 112 tumor samples; in 2 samples adequate RNA for RS was not obtained. We compared the adjuvant treatment initially planned according to institutional treatment protocol with the treatment given after RS. We compared the direct economic costs of CT with the costs of the diagnostic test, and performed a logistic regression analysis of some pathological factors and RS value.

Results
The RS could be determined in 110 of 112 cases, in which there was indication of adjuvant CT. Only 14 patients received CT (12.72%) with the RS value, so CT was avoided in 96 patients (87.28%).

The clinical-pathological characteristics of the series are summarized in the table 1. Of the risk factors analyzed, only grade 3 (p = 0.001) and PR <20% (p < 0.002) showed a statistically significant relationship with a higher probability of RS > 25. No association was found between age, nodal status, tumor diameter, Ki67, Infiltrating Ductal Carcinoma vs neither Infiltrating Lobular Carcinoma nor Lympho-Vascular invasion.

The cost of the genetic studies was 180000€ (1636€ each). The cost of each CT schedule (EC x 4 followed by paclitaxel x 12) was 7214€ and the total cost of 96 cases 692590€. Direct costs savings estimated from the reduction in CT treatment were 512590€

Conclusion: Our series shows that RS avoided unnecessary CT in 87% of cases and was more cost-effective than a previous series with MMP. G3 and RP <20 were the only pathological factors associated with an increased risk of RS > 25.

Is breast reconstruction safe in women over 70? An analysis of the national surgical quality improvement program (NSQIP) database

Fernando A Angarita¹, David R McCready¹ and Tulin Cil¹. ¹University of Toronto, Toronto, ON, Canada.

Background: Less than 14% of older women undergo post-mastectomy breast reconstruction. A major reason for the low rate is the concern about post-operative complications. A thorough analysis of surgical complications by age group is limited in previous studies. The aim of this study is to determine the surgical complication rates of older women (≥70 years old) with breast cancer who underwent breast reconstruction and compare them to younger women (18–69 years old).

Methods: Data from the National Surgical Quality Improvement Program (NSQIP) database were used to identify women with carcinoma in situ and invasive breast cancer who underwent delayed or immediate breast reconstruction (2005-2016). The primary outcome was 30-day post-operative surgical complications; the secondary outcome was 30-day mortality. Patient demographics, comorbidities, and 30-day postoperative complications and mortality rates were compared across age groups and each type of reconstruction.

Results: Of 42,929 women who underwent breast reconstruction, 2,615 (6.1%) were older women. Although compared to young women, older women were more likely to have medical comorbidities their American Society of Anesthesiologists’ (ASA) classification was lower. Tumor histology distribution was similar in both groups. Lymph node surgery and neoadjuvant chemotherapy was significantly less frequent among older women. Compared to young women, older women more frequently underwent immediate breast reconstruction (IBR) [n=2,405 (92%) versus n=33,580 (88.3%), p<0.0001] but less frequently underwent delayed breast reconstruction [n=209 (8%) versus n=4,734 (11.7%), p<0.0001]. Prosthesis-based reconstruction was the most common technique in both age groups. Autologous reconstruction was significantly less common amongst older women than young women [n=517 (19.8%) versus n=10,011 (24.8%), p<0.0001]. Older women experienced higher rates of superficial surgical site infection (SSI) [n=69 (2.6%) versus n=716, (1.8%), p=0.002] and urinary tract infection [n=15 (0.6%) versus n=101 (0.3%) p =0.005]. However, the rates of deep SSI, dehiscence, pneumonia, thromboembolism, renal complications, cardiac events, and sepsis were similar between both groups. Older women had significantly lower rates of events of bleeding requiring transfusion [n=27 (1%) versus n=736 (1.8%), p=0.002] and flap failure [n=2 (0.4%) versus n=210 (2.1%), p=0.006]. Return to the operating room within 30-days was similar between older and young women [n=171 (6.5%) versus n=2,821 (7.0%,) p=0.4]. Thirty-day deaths were rare events [older n=3 (0.1%) and young n=10 (0.02%), p=0.05].

Conclusions: Overall, 30-day postoperative complications in older women who undergo breast reconstruction are extremely low. Infection rates were slightly higher in the older group however; severe complications such as flap failure, bleeding, reoperation, and death were more common in young women. Age alone did not confer an increased risk of complications after breast reconstruction. Breast reconstruction can be safely offered to older women undergoing breast cancer treatment.
Enhance post-lumpectomy breast contour using oncoplastic surgery (OPS) plus a bioabsorbable 3-D tissue implant

Introduction: The appearance after breast surgery has become an important aspect of survivorship. The post lumpectomy/post radiation hollow surgical defect negatively impacts cosmesis and patient satisfaction. Oncoplastic procedures will mobilize surrounding tissues into the lumpectomy cavity but adds no volume to the breast. Use of a bioabsorbable 3-dimensional tissue implant (used for targeting radiation) has the additional benefit of adding volume to the breast and enhances the overall cosmetic appearance. Our experience over 3 years provides serial mammograms from which we may objectively categorize cosmetic contour. We report on our 2 and 3 year serial images of our treated patients compared with baseline.

Methods: Between May 2014 and June 2018, during lumpectomy for breast cancer we implanted a 3-D tissue implant marker in 170 patients, often combined with oncoplastic reconstruction and followed by radiation treatment. For long term follow-up we had 37 patients with serial mammograms at 2 or 3 years to assess cosmesis. All patients had interviews, physical exams, and serial mammograms to evaluate their cosmetic appearance. Both physician and patient graded their appearance. We also objectively measured and compared the pre-treatment mammogram and the 2-year and 3-year, post-treatment mammogram for symmetry and size using each breast as its own control. Using the post-treatment mammograms, we compared the relative anterior-posterior (depth) measurement of the quadrant bearing the implant as well as the non-cancer quadrant to the similar locations of the pre-treatment mammogram. Both mammogram positioning and radiation effects would balance. We compared the relative change from baseline in the non-cancer portion of the breast to the change from baseline in the cancer portion of the breast as a percent difference from baseline.

Results: Patients were treated with lumpectomy, oncoplastic reconstruction, and placement of a 3-D tissue implant. Three implants were removed due to positive margins. No implants were removed for any other reason. There have been no local recurrences. Overall, radiation oncologists felt the 3-D implant was useful for treatment planning in 85% of patients. Of the 37 consecutive patients who have completed an average of 27.8 months of follow-up, cosmesis was rated as excellent/good by clinicians (96%) and patients (94%). Mammograms taken at 2-3 years were compared with initial images. Whole-breast radiation effect varied among patients. Some had significant shrinkage while others had none. These changes were equal in the non-cancer post-radiation quadrants (86.2% vs 87%) demonstrating maintenance of normal breast contour. Our use of the 3-D implant and oncoplastic tissue advancement maintained the pre-operative contour of the breast after lumpectomy with radiation.

Conclusions: Breast cancer surgery and radiation is often complicated by poor cosmesis with retraction and volume loss. Using a combination of oncoplastic surgery combined with a 3-D tissue implant, we found the forward projection and contour of the breast at the lumpectomy site was preserved and patient satisfaction was good to excellent. Further investigation of the long-term cosmetic effects of breast cancer surgery should be encouraged.
The long-term outcomes of the BROWSE multicentre cohort study comparing Strattice™-assisted implant based reconstruction and submuscular reconstruction

Rebecca L Wilson1, Cliona C Kirwan1,2, Joseph M O'Donoghue3, Richard A Linforth4, Richard K Johnson1 and James R Harvey1,2. 1Manchester University NHS Foundation Trust, Manchester, United Kingdom; 2University of Manchester, Manchester, United Kingdom; 3Newcastle Hospitals NHS Foundation Trust, Newcastle, United Kingdom and 4Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom.

Introduction
Implant based reconstruction accounts for approximately 85% of reconstructions in the UK and 80% in the US with an increase in use of acellular dermal matrices (ADM) e.g. Strattice™. There is little long-term data on the outcomes of ADM reconstructions and its efficacy. Our aim was to establish the most comprehensive long-term surgical, cost-effectiveness, quality of life and cosmetic outcomes in three large UK reconstructive centres.

Methods
All women who had undergone immediate implant based breast reconstruction with Strattice™ or a submuscular technique between 2009 and 2015 across three tertiary centres in the UK were invited for prospective clinical (examination and tonometry), cosmetic and quality of life assessment. An eight year retrospective review of case notes, theatre database and implant log was performed.

Results
601 patients underwent 837 reconstructions. 589 Strattice™-assisted (331 therapeutic, 258 risk reduction) and 248 submuscular (152 therapeutic, 96 risk reduction). Revision surgery was performed in 43% of Strattice™-assisted reconstructions and 35% of submuscular within the follow-up period (p=0.034). Strattice™-assisted reconstructions were revised significantly sooner than submuscular, median time to first revision of 12 months vs. 21 months (p<0.0001). There was a significant reduction in the need for revision surgery for capsular contracture in the Strattice™-assisted group (Strattice™ n=19, submuscular n=16, p=0.04). Revision rates for capsular contracture in those having prior or adjuvant radiotherapy were 33% (n=9) in the Strattice™-assisted group and 66% (n=2) in the submuscular.

At a median time of 58 months from initial procedure, 10% in the Strattice™-assisted group and 14% in the submuscular had significant capsular contracture (Baker 3/4). At the time of assessment 7% of the Strattice™-assisted group and 17% of the submuscular had already undergone revision surgery for capsular contracture. Therefore, overall there was significantly more capsular contracture in the submuscular group (17% vs. 31%, p=0.047). There was no difference between the mean (of the four quadrant readings) breast tonometry reading between the two groups (0 hard – 10 soft). The median reading was 5.3 in the Strattice™-assisted group, 5.4 in the submuscular and 6.6 in native breasts. Those with Baker 1/2 had a median reading of 5.4 compared to 4.8 in those with a Baker 3/4 capsule.

Quality of life was equivalent between the two groups at a median time of 58 months. There was no difference in median Breast Q score for satisfaction with breasts, Strattice™-assisted 62 vs. submuscular 58 or satisfaction with outcome 67 vs. 75.

The mean cost of the index reconstructive procedure was less in the Strattice™-assisted group (£3634 vs. £4230) but there were no significant differences in long-term cost.

Conclusion
Long-term clinical outcomes support the use of Strattice™ in breast reconstruction. It reduces capsular contracture and enables patients to have their surgery in one rather than two procedures. The increased revision rate in the Strattice-assisted group was multi-faceted e.g. patient request to upsize and correction of contouring defects. Strattice™ reduces healthcare cost.
Evaluation of autologous fat grafting local morbidity (fat necrosis and biopsy rates) in breast reconstruction after breast cancer: A retrospective study on 257 patients in Oscar Lambret Center

Karine Hannebicque¹, Céline Renaudeau¹, Sylvia Giard¹, Claudia Regis¹, Loic Boulanger¹, Emilie Bogart¹, Marie-Cécile Le Deley¹, Luc Ceugnart¹ and Marie-Pierre Chauvet¹. ¹Oscar Lambret Center, Lille, Nord, France.

Background. Autologous fat grafting (AFG) is a widely used procedure in breast reconstruction after breast cancer. Indications are in constant increase but there is a lack of data about global morbidity, especially fat necrosis and management of local complications. The purpose of this study was to evaluate the complications rate in term of abnormal clinical examination or imaging and the proportion of additional explorations.

Methods. We retrospectively reviewed the computerized files of consecutive patients who underwent AFG for breast reconstruction after breast cancer or for preventive surgery and aesthetic sequelae after lumpectomy in the Oscar Lambret center between January 2013 and December 2016. Fat grafts were harvested with a fat trap then processed and injected according the Coleman technique. We collected demographics, operative details, local complications, incidence of palpable masses and/or suspicious breast imaging findings leading to additional explorations (breast imaging or biopsy), and locoregional cancer recurrence. Descriptive statistics were generated.

Results. Over a 4-year period, 257 women underwent autologous fat grafting for breast reconstruction and aesthetic sequelae after lumpectomy. Their mean age was 50 years [range 28-75], the mean BMI was 25 [range 18-44], 26% (n=66) were smoking and 74% (n=190) underwent radiotherapy. A total of 303 breasts were operated by 270 mastectomies (89%) or 33 lumpectomies (11%). The reconstruction was delayed in 63% (n=171) and the main techniques used were breast implant (44%, n=119) and autologous latissimus dorsi (31%, n=84). The mean number of fat grafting procedures was 1.9 per patient [range 1-7] with a mean volume of 181 mL [range 30-535]. The mean time interval between cancer diagnosis and first fat graft session was 56 months [range 3-285], and the follow-up ranged from 0 to 51 months (mean=16). The prevalence of donor site complications was 6% (n=16) and infections was 2% (n=5). Sixty six (25.6%) patients had a clinically palpable lesion and 54 (21%) underwent additional imagings, mostly by ultrasounds (53 patients, 98%) except the usual follow-up. Twenty one biopsies (8%) were performed and showed 16 benign results (76.2%) and 5 malignant results (23.8%) leading to 6.2% of fat necrosis and 1.9% of locoregional recurrence after AFG in our study. Tobacco (p=0.45), BMI (p=0.95), radiotherapy (p=0.56) and amount of fat grafted (p=0.09) didn’t appear to be risk factors for fat necrosis.

Conclusions. A good knowledge of local complications by surgeons and radiologists enables to avoid systematic and repeated further imaging explorations. Multicentric, prospective studies with long term follow up and evaluation of patients reported outcomes are needed to evaluate anxiety generated by biopsies and costs generated by repeated imagings.

Key words: autologous fat grafting, breast cancer, local morbidity, fat necrosis.
Prepectoral immediate implant-based reconstruction using Braxon® acellular dermal matrix – National audit from the United Kingdom

Mihir Chandarana¹ and Simon Harries². ¹University Hospitals of North Midlands, Stoke-on-Trent, Staffordshire, United Kingdom and ²Warwick Hospital, Warwick, United Kingdom.

Background
Implant based reconstruction is the most common method of reconstruction in the United Kingdom (UK) for women having a mastectomy for breast cancer or as a risk reducing procedure. Prepectoral reconstruction with full implant coverage using an acellular dermal matrix (ADM) – BRAXON - is a relatively new technique. Prepectoral reconstruction has the advantages of a better aesthetic outcome, less postoperative pain, quicker return to normal activities and no postoperative problems with animation. We report on the outcomes of prepectoral immediate breast reconstruction (IBR) using Braxon®ADM from a National audit.

Methods
A retrospective multi-centre audit of all direct-to-implant reconstructions using Braxon® in the United Kingdom was carried out. The demographic details, treatment details, short-term and long-term outcomes were evaluated. Factors affecting complication rates were analysed.

Results
Data from 406 Braxon reconstructions in 324 patients across 20 centres in the UK were collated. Mean age of the cohort was 50.48 (SD – 11.11, range – 20-82) years with a mean BMI of 26.05 (SD – 4.87, range – 18-42) kg/m². Demographic and treatment characteristics are given in Table 1.

</tbody>
</table>

The mean follow-up period was 10.94 months (0.3 to 34.8 months). The overall complication rate was 32% with a readmission rate of 16% and an implant loss rate of 9%. Of the factors evaluated for their effect on complication rates, patient age ($p = 0.005$), therapeutic mastectomy ($p = 0.001$), specimen weight ($p < 0.005$) and axillary nodal clearance ($p = 0.006$) were significantly associated with higher complication rate on univariate analysis.

**Conclusion**

Implant-based prepectoral breast reconstruction with Braxon® has satisfactory short-term and long-term operative outcomes, comparable to the National Mastectomy Audit data from the United Kingdom. Patient-reported outcomes, aesthetic outcomes and post-operative pain need to be evaluated. Further studies with larger numbers of patients and longer follow-up have been planned.
Prepectoral versus retropectoral implant-based breast reconstruction - The surgical and radiotherapeutical perspective

Christine Deutschmann¹, Daphne Gschwantler-Kaulich¹, Georg Dorffner², Christian Singer¹, Carmen Leser¹ and Daniela Kauer-Dorner¹. ¹Medical University of Vienna, Vienna, Austria and ²Medical University of Vienna, Center for Medical Statistics, Informatics and Intelligent Systems, Section for Artificial Intelligence and Decision Support, Vienna, Austria.

Background: Subpectoral implant positioning has been the standard of care in breast reconstruction despite involving disadvantages owing to the detachment of the pectoralis major muscle such as disruption of the muscle function, animation deformities and prolonged postoperative pain. Refined ablative techniques as well as dermal matrices and synthetic mesh products have led to the reintroduction of subcutaneous implant-based breast reconstruction possibly avoiding the negative sequelae of pectoralis disinsertion.

Objective: The primary objective of this study was to compare procedure-related complication rates following prepectoral versus retropectoral implant-based breast reconstruction. Furthermore the effect of the implant position on the quality of post-mastectomy radiation therapy (PMRT) was analysed.

Methods: All patients who underwent an implant-based breast reconstruction after mastectomy at the Department of Obstetrics and Gynecology of the University Clinic of Vienna within the years 1.1.2013 to 31.12.2017 were included in the study. A retrospective chart review of the patients was conducted assessing parameters regarding the mastectomy, the reconstruction, complications following the reconstructive procedure, patient-associated risk factors and radiation treatment plans. Complication rates were analysed one week, one month and one year after the implant-based reconstructive operation.

Results: In total 57 patients (94 breasts) were reconstructed following a prepectoral implant-placement approach, 95 patients (149 breasts) were reconstructed with implants in a retropectoral position. The two patient cohorts did not differ significantly in the occurrence of complications including the following dehiscence, infection, seroma, secondary bleeding, necrosis, fistula, capsular contracture and rippling. No significant differences regarding reinterventions and reoperations including seroma drainage, secondary suture and reoperation following secondary hemorrhage and necrosis could be detected between the two study populations. The two surgical procedures were not associated with a different rate of implant loss. 12 (2 in the cohort of patients with prepectorally placed implants and 10 in the subgroup of patients with subpectorally positioned implants) out of 152 patients needed PMRT for oncological safety. Prepectoral versus retropectoral implant positioning did not affect breast D_{mean} or D_{90}, heart D_{max} or V_5 or lung V_{20} across treatment plans.

Conclusion: The study demonstrated no inferior outcome regarding the occurrence of complications, reinterventions, reoperations and implant loss of prepectoral implant-based breast reconstruction compared to retropectoral implant positioning. Therefore, subcutaneous implant placement permits reconstruction of the breast with comparable procedure-related complication rates while avoiding disadvantages associated with the detachment of the pectoral muscle.

Regarding the radiation perspective both prepectoral and retropectoral implant positioning allow for optimal coverage of the chest wall with acceptable doses to the heart and lung.
Short-term outcomes and QoL following autologous fat transfer in oncoplastic and reconstructive breast surgery

Vesna Bjelic-Radisic¹,², Karin Oberfichtner¹, Paul Wurzer¹, Elisabeth Trapp¹, Thomas Rapp¹, Julia Reisniger¹, Lars-Peter Kamolz¹ and Karl Tamussino¹. ¹Medical University Graz, Graz, Austria and ²Helios University Clinic, Wuppertal, Germany.

Background: Breast cancer (BC) is with 30% among all cancers the most common cancer among women in Austria. Regarding therapy and management of BC, surgical treatments with resection and reconstruction play a crucial role. Breast-conserving therapy (BCT) represents a common procedure. However, mastectomy is still needed in about 30% of the patients with the diagnosis BC and as prophylactic surgery in indicated cases. Recently, autologous fat transfer (AFT, lipofilling) has been used to improve cosmesis in oncoplastic and reconstructive breast surgery. There is a gap of evidence for the oncological safety as well as the benefit for quality of life (QoL) in patients who had an AFT after the BC or prophylactic surgery.

Material and methods: We assessed peri-and postoperative results, oncological outcomes and QoL in 55 patients undergoing AFT after BCT or mastectomy at our department between 2013 and 2018. QoL was assessed with the EORTC QLQ C30 and QLQ-BRECON23 questionnaires.

Results: Overall, 55 patients (73 breasts) underwent AFT after BCT or mastectomy. 39 patients had a diagnosis of invasive BC (four bilateral) and six patients a diagnosis of DCIS. 24 mastectomies were done as prophylactic surgery. AFT was done in 22 cases with nipple sparing mastectomy (NSM), in 30 cases with skin sparing mastectomy (SSM), in 9 cases with simple mastectomy ± reconstruction and in 12 cases with BCT. The number of AFT sessions was 1-8 (mean 1.8). The injected fat volume per session was 30-390 ml. There were 10 (14%) complications: 3 hematomas (none needed reintervention), local inflammation requiring antibiotic therapy (n=3), formation of an oil cyst (n=1), and fat necrosis (n=3). In two cases of fat necrosis biopsy was performed to confirm the diagnosis. After a median follow-up of 34 months there was one recurrence (Paget’s disease after BC). QoL data will be presented at the meeting.

Conclusion: Lipofilling after mastectomy for cancer appears to be oncologically safe. Our complication rate is relatively high, although additional surgical intervention (biopsy) was only necessary in two cases. Patients considering AFT should be informed about additional risk for biopsy, as well as other common complications.
Applications of rib sparing technique in internal mammary vessels exposure of abdominal free flap breast reconstructions

Qi Zhang¹², Qin Xiao¹, Rong Guo¹², Jiong Wu¹²³, Yajia Gu¹ and Bingqiu Xiu¹². ¹Fudan University Shanghai Cancer Center, Shanghai, China; ²Fudan University, Shanghai Medical College, Shanghai, China and ³Collaborative Innovation Center for Cancer Medicine, Shanghai, China.

Background:
Internal mammary vessels (IMVs) are widely used recipient vessels in abdominal free flaps breast reconstructions. Exposure of IMVs usually needs to resect a segment of costal cartilage or rib during the operations. The rib sparing technique is an alternative method with less damage. This study aims to analysis the applicability and advantages of rib sparing technique of IMVs exposure in breast reconstruction.

Methods:
Medical records of 215 patients who underwent abdominal free flap reconstruction from November 2006 to December 2017 were analyzed. The factors influencing the choice of vessels and rib sparing were analyzed. The outcomes of rib sparing were assessed. Intercostal space (ICS) width and other related data were measured by the preoperative thin slice chest computed tomography (CT) scan images.

Results:
Among all 215 patients with 218 flaps, 172 flaps used IMVs as the recipient vessels while 13 used thoracodorsal vessels and 33 used subscapular vessels. The proportion of IMVs as recipient vessels showed a rising trend in general and remained over 90% for the last three years in our center. Patients with immediate reconstruction (p=0.005) and axillary lymph nodes dissection (ALND) (p<0.001) were less likely to use IMVs, both in univariate and multivariate logistic regression analysis. Patients' BMI and radiotherapy history showed no statistically significant differences between the IMVs group and the other vessels group (p=0.338 and 0.811). The rib sparing rate in IMVs exposure increased yearly and exceeded 40% in 2013, now it maintained more than 60% during the recent 3 years. Additionally, among the patients who received rib sparing IMVs exposure in 2017, the mean ICS width was relatively smaller than that in 2013 (2.54 cm VS 2.93 cm, p=0.124). Compared with rib resection group, patients with rib sparing were higher (163.57 ± 4.44 cm vs. 161.83 ± 4.30 cm, p=0.047) and with a wider ICS (2.65 ± 0.54 cm vs. 2.25± 0.38 cm, p<0.01), while the depth from the surface of the pectoralis major muscle to the IMVs and distance between the parasternal line and IMVs had no difference between the two groups. Rib sparing group has a shorter surgery and hospitalization time, as well as a lower severe complication rate, but the differences were not statistically significant (p= 0.120, 0.450 and 0.296).

Conclusion:
IMVs were used more frequently as the recipient vessels in abdominal free flap breast reconstructions, especially when axillary operation was not carried out at the same time. Rib sparing technique had the potential to decrease surgery time and hospitalization days, as well as the severe complications rate. It could be used in most of patients received free flap reconstruction when IMVs were used, particularly in higher patients and patients with a wider ICS. Preoperative slice chest CT scan can be used to measure the ICS width to provide suggestions for dealing with the ribs.
Same-day surgery impact on breast reconstruction program in a public healthcare system: An affordable booster

Juan E Bargalló-Rocha¹, Luz M Gutiérrez-Zacarías¹, Alejandro Maciel-Miranda¹, Johnatan Figueroa-Padilla¹, Monica Drucker-Zertuche¹, Nereida Esparza-Arias¹, Angel Elizalde-Méndez¹ and Paula A Cabrera-Galeana¹. "Instituto Nacional de Cancerología, Mexico City, Tlalpan, Mexico.

Background
Breast cancer represents the most common malignancy in Latin America, and since 2006 it is the cancer type with the highest incidence among Mexican women. Providing multidisciplinary high-quality care for the growing population of patients with breast cancer represents a challenge to low and middle-income countries, which have limited economic resources and limited health staff and facilities.

Since 2007, Seguro Popular insurance program has provided coverage for the treatment of women with breast cancer, including surgery, radiotherapy, chemotherapy, endocrine therapy and Her2-targeted treatments; before this program up to 50% of the Mexican population did not have healthcare coverage, and had to pay out of pocket for cancer care. Unfortunately, due to financial constraints, this does not include other interventions which may be relevant, such as supportive care and reconstructive surgery.

National Cancer Institute of Mexico (INCan) is a part of the Mexican federal government and as such provides care to uninsured individuals with all types of malignancies, including breast cancer. Since the start of Seguro Popular insurance program (2007), INCan has provided oncological care to over 5,000 women with breast cancer.

In 2012, INCan received a grant from the federal government (P017 Reproductive Health and Gender Equality in Health Grant) in order to establish the “Post-Mastectomy Program” (PMP), which aimed providing free patient navigation, supportive care and breast reconstruction for women after mastectomy. Starting on July 2016, derived from PMP, it was possible the setting of a Same-Day Surgery Facility (SDSF) at INCan: two small, fully equipped operation rooms with a small recovery area; and the hiring of 4 nurses and 2 anesthesiologists, adding all this to the one main operation room already set for breast cancer surgery. This allowed an increase in all kind of breast cancer surgery: conservative surgery, mastectomy with sentinel lymph node and breast reconstruction procedures. One of this rooms was assigned to breast reconstructive surgeries.

Material and Methods
Data were retrospectively collected from a 5 year period, 30 months before SDSF and 30 months after SDSF. Before SDSF an average 66.4 (54-73) of breast reconstruction surgeries were done by six month period, total of 332 breast reconstruction surgeries. After implementation of SDSF an average of 124 (107-138) by six month period, with a total 621 surgeries, which represents an 87% increase in breast reconstruction procedures for the same time period.

Conclusion
Same day surgery has been proven before to be safe in breast cancer surgery and in breast reconstructive surgery when co-morbidities are accounted for.

This work shows that implementation of Same-Day Surgery could be a tool to increase the offer of breast reconstruction in economically restrained systems, in early or experienced breast reconstruction programs in developing economies, and even in developed ones.

In our experience, this approach achieved an 87% increase in breast reconstruction procedures, in a 30 month period, which allowed us to benefit more women and offer them a better quality of life.
Post-mastectomy radiotherapy following immediate implant based reconstruction: A possible solution to a reconstructive challenge

Phakanant Chaichanavichkij¹, Kirpakaran S Arun¹, John Conibear¹ and Mohammed Z Ullah¹. ¹Bart's Health NHS Trust, London, United Kingdom.

**Aims:** The National Mastectomy and Breast Reconstruction Audit report (NMBRA, 2011)¹ revealed that immediate implant-based breast reconstruction (IIBR) was the most common type of primary reconstruction performed in the UK (37%). The main reason given by clinicians for not offering immediate breast reconstruction was the need for adjuvant radiotherapy. Post-mastectomy radiotherapy (PMRT) decreases the rate of local recurrence as well as increase the long-term survival in patients who demonstrate intermediate to high-risk features²,³ but has been shown to increase the risk of implant complications in IIBR by up to 24% (Berry et al, 2010)⁴. Cordeiro et al (2004)⁵ showed the incidence of capsular contracture was 28% higher in the PMRT group compared with non-irradiated patients. Most patients in the UK receive hypofractionated PMRT of 40.05Gy in 15 fractions over 3 weeks based on the UK Standardisation of Breast Radiotherapy (START) trial⁶, which demonstrated that hypofractionated PMRT is as safe and effective as the conventional PMRT of 50Gy in 25 fractions over 5 weeks. The aim of this study was to determine whether the conventional PMRT of 50Gy in 25 fractions over 5 weeks (2Gy per fraction) was associated with a reduced risk of implant complications in patients undergoing mastectomy with IIBR compared with hypofractionated PMRT regiment of 40.05Gy in 15 fractions over 3 weeks (2.67Gy per fraction).

**Methods:** A single centre retrospective review of data on patients who underwent IIBR followed by PMRT between September 2012 and May 2017 was conducted. Radiotherapy-related complications (surgical site infection, contracture, implant rupture or leakage, wound breakdown) were compared between the two groups of patients receiving conventional and hypofractionated PMRT.

**Results:** Fifty-nine patients underwent IIBR followed by PMRT. Twenty-six patients received hypofractionated PMRT and thirty-three patients received conventional PMRT. Radiotherapy-related complications occurred in 62% of patients in the hypofractionated PMRT group compared with 45% in the conventional PMRT group (p = 0.30). The incidence of capsular contracture (31% in vs. 21%, p = 0.55) and wound breakdown (23% vs. 15%, p = 0.51) was higher in the hypofractionated PMRT group, but surgical site infection (SSI) was more common in the conventional group (4% vs. 6%, p = 1.00).

**Discussion:** Possible confounding factors (BMI, smoking status, and adjuvant chemotherapy) were not analysed due to the small sample size and limitations of the retrospective nature of this study. However, our overall rate of SSI is low in comparison with national data from the NMBRA (2011), which states the SSI rate of 25% in patients who underwent breast reconstruction surgery. 

**Conclusions:** This study suggests that the rate of radiotherapy-related complications is lower in patients treated with conventional PMRT compared with hypofractionated PMRT, however the sample size is too small to demonstrate statistical significance. Further research is required to evaluate the effectiveness of conventional PMRT as an option to facilitate immediate implant-based reconstruction following mastectomy.
Intraoperative central nipple biopsy in subcutaneous mastectomies - A retrospective analysis of 200 patients

Christian Eichler¹,², Sophia Stephan¹, Fabinshy Thangarajah², Julian Puppe² and Warm Mathias¹,². ¹Breast Cancer Center, Municipal Hospital Holweide, Cologne, Germany and ²University of Cologne, Cologne, Germany.

Background: Subcutaneous nipple sparing mastectomies (NSM) are an important tool in modern oncoplastic surgery. Especially when an immediate implant-based reconstruction (IBR) is desired, clean margins are of the utmost importance. Central nipple biopsies during surgery serve two main purposes. Most importantly, it is hypothesized that a general recurrence risk reduction occurs due to elimination of glandular and ductal components within the nipple. In addition, intraoperative pathological evaluation of this biopsy may increase clean margin resection rates. This trial aimed to evaluate complication rates, local recurrence and clean margin resection rates in a head-to-head retrospective manner.

Methods: Starting in 2015, intraoperative central nipple biopsy in NSM with IBR was introduced at the Municipal Breast Cancer Centre Cologne, Holweide, Germany. This trial evaluates global complication rates (necrosis, implant loss, seroma and hematoma), long term local recurrence and clean margin status for cohort 1 (n=100) SSM with nipple biopsy vs. cohort 2 (control, n = 100) without nipple biopsy. In case of an involved central nipple biopsy, the nipple areola complex was removed. This analysis is a single center, multi-surgeon, retrospective, head to head analysis. Median follow-up is three years. All IBR procedures used an epipectoral implant pocket.

Results: Global complication rates did not differ significantly between both cohorts. There was no increased rate of implant loss and or revision surgery. Within the medium three-year follow-up there was no case of local recurrence within nipple areola complex for both cohorts. An Involved central nipple biopsy was however found in 2% (n=2 /100) of the performed SSM procedures leading to the immediate removal of the nipple areola complex. Surgical time did not increase with central biopsy. A significantly higher rate of re-surgery due to involved margins was shown in the control cohort.

Conclusions: This analysis showed that intraoperative evaluation of the ductal components of the nipple is a safe procedure. At least 2% of the patients showed an immediate advantage of this procedure since clean margins were obtained by removing the nipple areola complex during the same surgery. The medium follow-up showed no significant difference in local recurrence. We therefore strongly, recommend a central nipple biopsy for all NSM procedures.
Implementation and outcomes of a microsurgical breast reconstruction program at a public cancer center in Mexico

Daniela Vargas-Salas¹, Johnatan Figueroa-Padilla¹, Enrique Soto-Perez-de-Celis¹, Alejandro Maciel-Miranda¹, Eric Santamaria¹, Luz M Zacarías-Gutierrez¹, Paula Cabrera-Galeana¹ and Enrique Bargallo-Rocha¹, ¹Instituto Nacional de Cancerologia, Ciudad de Mexico, CDMX, Mexico and ²Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, CDMX, Mexico.

Background: Breast cancer (BC) is the most common malignancy in Mexico, and although many Mexican women need breast reconstruction, this is not covered by most public insurance schemes. The National Cancer Institute of Mexico (INCan), located in southern Mexico City provides care to uninsured individuals with all types of malignancies, including BC. In 2012, INCan received a grant from the Mexican federal government in order to establish the “Post-Mastectomy Program” (PMP), aimed at providing free breast reconstruction to women after mastectomy. Here, we describe the implementation and outcomes of our microsurgical breast reconstruction program.

Methods: We retrospectively reviewed medical records of all patients undergoing microsurgical breast reconstruction after mastectomy at INCan between the establishment of the PMP in 01/2013 and until 12/2017. Sociodemographic, clinical and surgical characteristics were collected. We also recorded for the presence of complications directly related to the reconstructive procedures, including local complications (infections, necrosis, thrombosis etc.), flap loss, need for reoperation and hospitalization time. Data were analyzed using descriptive statistics such as means, medians and proportions.

Results: 161 microsurgical breast reconstructions were conducted at INCan between 01/2013 and 01/2017, ranging from 23 in 2013 to 41 in 2016. Median patient age was 45 years (y) (21-66), and 57% had < high school education. 2.5% had diabetes, 9.9% hypertension, and 2.5% rheumatologic diseases. Median body mass index was 26.8 (18.2-39), 82.6% were non-smokers and 46.5% (n = 108) had previous abdominal scars. Regarding reasons for mastectomy, 67.7% were due to invasive BC, 11.8% to ductal carcinoma in situ, and 5.6% to BRCA mutations. Of the 109 invasive carcinomas, 21.8% were stage I, 57.3% stage II, and 20% stage III; 21.7% received neoadjuvant chemotherapy. 125 patients underwent immediate reconstruction, of which 89 used unilateral deep inferior epigastric perforator flaps (DIEP), 35 bilateral DIEPs, and 1 other technique. Mean preoperatory albumin was 4.2g/dL (SD 0.35), while mean preoperative hemoglobin was 14.2g/dL (SD 1.2). 41.6% of the patients (n = 67) had at least one surgical complication, with the most common being delayed wound healing in 17% and fat necrosis in 14%. 26% of patients had to be reoperated, and flap loss occurred in 13% (n = 21). No differences were noted in the clinical or surgical characteristics of patients with or without flap loss. Median length of stay was 6 days (range 2-17).

Conclusions: This is the first detailed description of the outcomes of a microsurgical reconstruction program in a country with limited resources. Developing and implementing such a program is feasible, and may provide access to breast reconstruction to women who would normally be unable to obtain it.
Acellular dermal matrices (ADM) were used to cover the implant to reduce implant rotations and to improve esthetic results. Current retrospective data on complication rates are heterogeneous. Prospective data are rare. Primary objective was to evaluate the explantation rate.

11 German sites, with experience in breast reconstruction using ADM, have been selected for participation in this study. Patients were enrolled according to predefined in- and exclusion criteria into two cohorts: group A - primary reconstruction and group B - secondary reconstruction after capsular contracture.

After documentation of baseline characteristics and surgical parameters, endpoints such as rate of seroma, red breast syndrome, infection and explantation were assed at 1 day, 7 days, 1 month, 3, 6 and 12 months after surgery. In addition, patient- and surgeon-satisfaction were recorded.

Data of 83 patients were analyzed (A: 50, B: 33). In 29 patients Epiflex was used bilaterally, so that it was used 112-times in total.

The average age of the patient was 45.1 years (A: 41.5; B: 50.3), the average BMI was 22.2 (A: 22.3; B: 22.1).

In total, 17.0 % seromas (A: 19.4 %; B: 12.5 %), 10.7 % red breast syndrome (A: 9.7 %; B: 12.5 %), 4.5 % infections (A: 6.9 %; B: 0 %) and 5.4 % explantations (A: 6.9 %; B: 2.5 %) were observed.

During the average observation period of 8 month, the satisfaction of the patients and surgeons was high at all measured time points. On a scale from (1 - very satisfied to 6 - not satisfied) the satisfaction of patients and surgeons was 2.3 (A: 2.3; B:1.9) and 2.0 (A: 2.2; B: 1.8) respectively.

Our data show, that both patients and surgeons are generally satisfied with the outcome of breast reconstruction using ADM. Complication rates were adequate and commonly lower in secondary reconstructions.
Outcome of lipofilling in patients with a history of breast cancer: A retrospective cohort study

Filip Thiessen¹, Lennert De Schrijver¹, Marjolijn De Decker¹, Thierry Tondu¹, Mireille Van Goethem¹ and Wiebren AA Tjalma¹.
¹Antwerp University Hospital - University of Antwerp, Edegem, Antwerpen, Belgium.

Background: Autologous fat grafting [AFG] is a surgical technique used to correct breast deformities or to reconstruct partial breast deformities after breast conservative treatment [BCT] or mastectomy for breast cancer. However, a strong debate remains upon the topic of safety and the oncological risk after lipofilling. There is a need for more studies assigned with a higher level of evidence.

Objective: This retrospective cohort study aimed to provide a strong evidence-based argument concerning the safety of fat grafting in patients who underwent breast cancer surgery in comparison to a group with similar characteristics who did not receive lipofilling.

Methods: Two cohorts consisting of women with a history of breast cancer were retrospectively assembled. All patients underwent BCT and/or a mastectomy as breast cancer treatment. An intervention population of patients that had received primary or secondary lipofilling was statistically compared to a control population of patients that had received a breast reconstruction without lipofilling.

Results: Fifty patients with a mean age of 53.6 ± 9.3 years at the time of lipofilling were included in the intervention cohort. The control group included 67 patients with a mean age of 52.8 ± 8.5 years at the time of breast reconstruction. Both cohorts showed no significant differences for demographic or oncological data. Mean follow-up time was 15.0 ± 15.6 months in the intervention group and 45.4 ± 35.1 months in the control group. The prevalence of the complications are shown in the table.

No complications were seen in 35 patients [70%] after lipofilling. Fat necrosis was mostly observed [n=15] but no infections or local oncological recurrences were reported. In the control group a complication-free follow-up occurred in 38 patients [56.7%] after breast reconstruction. One control patient demonstrated a local oncological recurrence. A higher prevalence of infections was observed in the control population [p = 0.048] and the prevalence of fat necrosis was higher after lipofilling [p = 0.028].

Conclusion: Lipofilling is a safe technique for breast reconstruction in patients with a history of breast cancer. There is no increase in local oncological recurrence. A side effect is an increase in fat necrosis which can potentially lead to more investigations.
INTRODUCTION
Achieving breast symmetry and mitigating ptosis are important aims of cosmetic and reconstructive breast surgery. Breast asymmetry typically occurs when the left and right breasts differ in size, shape, or position. A few studies have associated breast asymmetry to hormonal changes and breast cancer risk. Similarly, changes in breast ptosis have been attributed to age, BMI, breast volume, smoking history, pregnancy, and weight loss. The purpose of this study is to provide normative data and understand factors that may attribute to breast asymmetry and ptosis.

MATERIAL AND METHODS
The dataset consisted of 87 surface images of women scheduled to undergo mastectomy for the prevention or treatment of breast cancer. Patients were enrolled in an IRB approved research study from 2011 to 2014 at MD Anderson Cancer Center (Houston, TX). Images were obtained using 3dMDTorso (3dMD LLC, Atlanta, GA). Patient demographics were recorded and tumor size was obtained from MD Anderson Breast Cancer Management System, and tumor location data were obtained through a search of the MD Anderson Tumor Registry Database. Patients with a BMI > 41, rare congenital breast abnormalities, radiation therapy, or major breast surgeries were excluded. Breast symmetry was assessed by computing the ratio of the sternal notch (SN) to nipple (N) distance and breast volume ratio of the left and right breasts. Perfect symmetry occurs when the ratio is one. The smaller breast was evaluated over the larger breast so that ratios were less than one. A plastic surgeon rated each breast for ptosis. The correlation between age, BMI, and symmetry parameters were assessed using Pearson's r, Spearman's rho, and Kendall's tau coefficients. A multivariable linear model was used to evaluate the association between the ratios and demographic factors. A multiple ordinal logistic regression analysis was performed for age, BMI, and breast volume against ptosis.

RESULTS
The average sternal notch to nipple (SN-N) distance was 24.1 ± 3.30 cm and the SN-N ratio was 0.975 ± 0.020. The average breast volume was 794 ± 323 cc and the breast volume ratio was 0.914 ± 0.065. When comparing the right and left breasts, for SN-N distances, we found that 58.6% of the patients had a difference of less than 5 mm, 17.3% of the patients had a difference between 5 and 10 mm, and 24.1% of the patients had a difference greater than 10 mm. For volume, 49.4% of the patients had less than 50 cc of difference, 21.5% of the patients had a difference between 50 and 100 cc, and 29.1% of the patients differed by more than 100 cc. Tumor size did not significantly affect breast volume based on the t-test (p = 0.181). Symmetry ratios did not show significant correlation with age or BMI. Age and BMI were also not significantly associated with ptosis (p>0.05), but larger breast volumes were associated with increasing degree of ptosis (OR: 1.14; 95% CI: 1.06-1.22; p<0.001).

CONCLUSION
Our findings indicate that larger breast volumes are associated with increased ptosis grade. Age and BMI did not appear to significantly impact asymmetry or ptosis.
Reconstructive breast surgery with partially absorbable bi-component Seragyn® BR soft mesh: An outcome analysis

Anna Machleidt¹, Nora Schmidt-Feuerheerd², Jens-Uwe Blohmer¹, Ralf Ohlinger³, Janina Küper¹, Gabriel von Waldenfels¹, Sissi Dittmer⁴, Stefan Paepke⁴ and Evelyn Klein⁴. ¹Charité-Universitätsmedizin, Breast Center, Berlin, Germany; ²Martin-Luther-Krankenhaus, Berlin, Germany; ³Universitätsmedizin Greifswald, Greifswald, Germany and ⁴Klinikum rechts der Isar, Munich, Germany.

Objective: Synthetic meshes and acellular dermal matrices are increasingly used in implant based breast reconstruction. The objective of this study was to determine the incidence and severity of complications following the implantation of the partially absorbable bi-component soft mesh SERAGYN® BR and assess risk factors for adverse operative outcomes.

Methods: A retrospective clinical study was performed: The SERAGYN® BR soft mesh was utilized in 148 operations (skin-sparing mastectomy, nipple-sparing mastectomy, breast conserving surgery, secondary reconstruction after mastectomy) in four different institutions in Germany from June 2012 to February 2014. We analyzed whether the results were affected by tumor morphology (e.g. grading), patient characteristics and co-morbidities, previous surgery or therapies and use of alloplastic materials.

Results: The SERAGYN® BR soft mesh was successfully implanted in 131 of 148 operations. The rate of reconstructive failure was 11.5%. The most common complication was seroma (25.7%), followed by hematoma and skin infection (each 14.2%). Wound healing issues were detected in 13.5% cases, secondary wound infections in 10.8%. 83.8% of operations had no severe complications. Independent predictors for reconstructive failure were wound healing issues, nipple- or skin necrosis, wound- or skin infections, a high volume of excised tissue, hematomas, seromas and sentinel lymph node excisions. A higher body mass index was correlated with a higher rate of infection.

Conclusion: SERAGYN® BR mesh can be used successfully in breast reconstructive surgery. Rates of major complications or reconstructive failure are comparable to the use of other synthetic or biological meshes.
Titanium-coated polypropylene mesh for immediate implant-based breast reconstruction – Our initial experience

Asma Munir¹, Simon Holt¹, Anita Huws¹, Sohail Khan¹, Yousef Shariaha¹ and Saira Khawaja¹. ¹Prince Philip Hospital, Llanelli, Wales, United Kingdom.

**Background:** The use of titanium-coated polypropylene mesh (TCPM) is an alternative to a-cellular dermal matrix for the implant based breast reconstruction by providing extra implant coverage especially in the lower half. The aim of our study was to analyze short-term outcomes of TCPM based implant breast reconstruction and compare the patient- and procedure-related factors to implant loss and surgical complications.

**Methods:** Between 2013 and 2016, implant breast reconstructions after conservative mastectomies using TCPM was performed in 50 patients (with 58 reconstructions). Complications were divided into major (need for additional surgery), minor (conservative treatment), and implant loss. Univariate analyses were performed to determine the influence of the patient- and procedure-related factors on postoperative complications and implant loss.

**Results:** Fifty patients had therapeutic mastectomies with 8 of them also had contra lateral risk reducing mastectomies. With median follow-up of 17.5 months, four of 50 patients had implant loss. Reasons for implant loss were skin necrosis in 2 cases, infection in 1 case and necrosis with infection in another case. One of these patients had a revised reconstruction one year later. One additional patient required implant replacement because of capsule contracture. No risk factors were observed for patient-associated complications. Univariate analysis revealed an increased risk for implant loss in patients with skin necrosis ($p < 0.01$).

**Conclusions:** This titanium-coated polypropylene mesh shows acceptable complication rates and its use in immediate implant breast reconstruction is safe and effective.
Oncologic outcomes and reconstruction quality of immediate autologous breast reconstruction in intermediate and locally advanced breast cancer

Won Sup Yoon¹, Dae Sik Yang², Gil Soo Son¹, Sang Uk Woo², Deok-Woo Kim¹, Eun-Sang Dhong² and Young Woo Chang¹.
¹Ansan Hospital, Korea University Medical Center, Ansan, Republic of Korea and ²Guro Hospital, Korea University Medical Center, Seoul, Republic, Republic of Korea.

Purpose: We analyzed oncologic outcomes and reconstruction quality in locally advanced stage breast cancer after performing immediate autologous breast reconstruction (IABR).

Methods: From 2007 to 2014, data of patients with stage II-III breast cancer of ≤ 70-years-old who received total mastectomy (TM) from two institutions were extracted. Exclusion criteria were: previous contralateral breast cancer, follow-up loss before adjuvant therapy completion, and artificial reconstruction. Patients were divided into two groups; 1) TM alone and 2) TM+IABR. Overall survival (OS) and loco-regional recurrence free survival (LRRFS) were calculated and minor revision, abnormal volume on CT, and breast height change were observed.

Results: Sixty-one of 188 patients received IABR after TM. Neoadjuvant chemotherapy and postoperative radiotherapy was done in 27 and 80 patients, respectively. Fifty-nine percent, 19.2%, and 21.8% of patients were in stage II, IIIA, and IIIB-C, respectively. Stage IIIB-C was the most important prognostic factor for OS and LRRFS. In a median of 56.8 follow-up months, 5-year TM and TM+IABR OS rate were 96.8% and 100% for stage II (P=0.324) and 57.6%, 95.5% and 91.7% for stage IIIA (P=0.698), and 62.5% for stage IIIB-C (P=0.544), respectively. Five-year TM and TM+IABR LRRFS were 98.1% and 95.7% for stage II (P=0.998), 91.1% and 100% for stage IIIA (P=0.277), and 70.8% and 62.5% for stage IIIB-C (P=0.378), respectively. However, two locoregional failures after 5-years were developed in stage IIIB-C of TM+IABR at 71 and 94 months. Minor revisions 3 months of IABR, including two major complications, were done in 49.2%. The reduction of breast height was 21.2% (11/52) and 31.9% (15/47) in about 18 months and about 42 months observations after IABR, respectively. The volume of abnormal imaging was over 10 cc in 27.3% (15/55) on CT of 6 months after IABR. Although minor revisions, abnormal volume on CT, and breast height change were common, they were not related to therapeutic methods, including radiotherapy and tumor stage.

Conclusions: In about 5-years follow-up, IABR did not aggravate oncologic outcomes, and adjuvant radiotherapy was not closely related with quality of reconstruction. It must be considered, however, that absolute oncologic outcomes of advanced stage were not sufficient, and minor problems post-IABR were commonly developed.
Patient-derived organoid models of inflammatory breast cancer

Jennifer M Rosenbluth¹, Ioannis Zervantonakis², Mackenzie Boedicker², Nikhil Wagle¹, Deborah Dillon³, Faina Nakhlis³, Joan S Brugge² and Beth Overmoyer¹. ¹Dana-Farber Cancer Institute, Boston; ²Harvard Medical School, Boston and ³Brigham and Women's Hospital, Boston.

Background: Inflammatory Breast Cancer (IBC) is an aggressive subtype of breast cancer that is associated with an increased likelihood of early metastasis and a poor prognosis, accounting for approximately 10% of all breast cancer mortality. Currently, there is limited availability of cell line and patient-derived xenograft (PDX) models of IBC. As a result, there is an urgent need for additional model systems to facilitate our understanding of this disease. Organoids have been used to grow breast cancer cells with high efficiency, resulting in long-term cultures with genetic and phenotypic stability; however, the extent to which IBC can be modeled using this system is unknown. We undertook an evaluation of organoid culture technology for growing IBC patient samples, with the goal of generating a model of IBC that more faithfully recapitulates the key features of the disease.

Methods: Tumor samples (taken from lumpectomy, mastectomy, PDX, or core biopsy samples), were digested to the organoid level using collagenase, and were grown in three dimensional cultures using a basement membrane extract and a fully-defined organoid medium, as described (Sachs et al. Cell 2018). First, we surveyed non-IBC metastatic breast cancer samples to determine the efficiency of growth of multiple breast cancer subtypes under these conditions. Then, we assessed the efficiency of growth of IBC samples taken after treatment, at the time of mastectomy. Co-culture experiments in which IBC organoids were grown in the presence of human endothelial cells were performed in three dimensional culture using a mixture of type I collagen and basement membrane extract.

Results: Our success rate for establishing organoid cultures from breast cancer samples in general was 75% (33 out of 44 samples), and for triple-negative breast cancers, the success rate for establishment of organoid cultures was 100% (14 out of 14 samples). Expansion of ER+ tumor organoids (16 of 26 samples) was primarily restricted by a slow growth rate in culture, as compared to triple-negative tumor organoids. We were able to establish 12 breast cancer organoids from core biopsies of multiple metastatic sites, including brain, liver, bone, breast, and skin. We subsequently were able to establish organoid cultures from five out of five IBC tumor samples. Our IBC organoids preserved histopathologic features of the original tumor, and expressed key markers, such as E-cadherin, that are known to be associated with IBC. In addition, our IBC organoids interacted with human endothelial cells under co-culture conditions designed to model lymphovascular invasion, an essential feature of IBC.

Conclusion: We have shown that organoid cultures can be established to propagate IBC tumors with high efficiency, preserve key pathologic features of IBC in vitro, and model interactions between tumor cells and the microenvironment. Thus, organoids are useful complements to existing IBC models, and can be used to identify potential therapeutic vulnerabilities associated with this particularly aggressive breast cancer subtype.
Dissecting the biology of inflammatory breast cancer (BC) through cell free DNA and a circulating tumor cells (CTC)-derived signature

Lorenzo Gerratana1,2, Qiang Zhang1, Chun Wang3, Ami Shah1, Andrew A Davis1, Zhong Ye3, Youbin Zhang1, Maysa Abu-Khalaf3, Lisa Flaum1, Kimberly Strickland1, Giovanna Rossi3,4, Amir Behdad1, William Gradishar1, Leonidas Platanias1, Hushan Yang3 and Massimo Cristofanilli1. 1Robert H. Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL; 2University of Udine, Udine, UD, Italy; 3Thomas Jefferson University, Philadelphia, PA and 4Ospedale dell’Angelo – Ospedale SS. Giovanni e Paolo, Venezia, VE, Italy.

Background: The biological characteristics conferring Inflammatory BC’s (IBC) distinctive and aggressive clinical features are currently not fully clarified. The aim of this study is to dissect IBC’s biology through the integration of DNA and CTC-based circulating biomarkers.

Methods: This study retrospectively analyzed 251 Advanced BC (ABC) patients (pts) treated and longitudinally characterized for CTCs and circulating tumor DNA (ctDNA) at Thomas Jefferson University (Philadelphia, PA) and Northwestern University (Chicago, IL). CTCs were enumerated through CellSearch (Menarini Silicon Biosystems), and characterized for HER2 expression using the CellSearch CXC Kit, while ctDNA was analyzed using the Guardant360 NGS assay (Guardant Health) and its percentage (%ctDNA) was classified based on the previously reported cut-off of 5.7% (Gerratana et al 2018). A subset of 117 pts was further characterized for circulating cell-free DNA (ccfDNA) through Qubit® dsDNA HS quantitation Assay (Thermo Fisher Scientific) and quantitative real-time PCR assay for ALU DNA repeats on chromosome 1. Associations between clinical characteristics, CTCs-derived biomarkers and IBC were explored through Fisher’s exact test; survival was tested though Cox regression and log-rank test.

Results: Of the total 251 pts, 115 were diagnosed with IBC. Among the 117 patients characterized for ccfDNA, 70 had IBC. Median ccfDNA was 1.59 for IBC (IQR 1.02-3.19) and 2.37 for non-IBC (nIBC) (IQR 1.13-3.52), P=0.27. Consistent results were observed for %ctDNA levels (median value: 2 vs 1.6). The impact on OS of ccfDNA after log transformation was significant for the total population (HR 1.73 95%CI: 1.11-2.69) but not in IBC pts (HR 1.40 95%CI: 0.84-2.34). On the other hand, ctDNA high pts had a significantly worse OS (nIBC: HR 5.34 95%CI: 1.70-18.81 P=0.004; IBC: HR 4.05 95%CI: 1.91-8.58 P< 0.001). In the ctDNA high subgroup no differences in total number of CTCs were observed between IBC and nIBC, while significantly lower CTCs were observed in ctDNA low IBC pts (P=0.0097). The ctDNA low IBC subgroup had a higher incidence of HER2 positive BC (P=0.003) and a significantly lower incidence of CTCs clusters (P=0.006), HER2 positive CTCs (P=0.041). Notably, no associations were observed with stage at baseline, number of metastatic sites, liver, lung and visceral involvement. On the other hand, the ctDNA_high IBC subgroup was characterized by a lower incidence in liver, bone and visceral involvement (P=0.017, P=0.014 and P=0.03 respectively) and a marginally high incidence in soft tissue involvement (0.084). Moreover, IBC diagnosis conferred a significantly worse prognosis only in the ctDNA low subgroup (OS at 12 months nIBC: 100% vs IBC: 70%; P=0.049), while no differences were observed in the ctDNA_high subgroup (OS at 12 months nIBC: 29% vs IBC: 26%; P=0.767).

Conclusion: ctDNA is able to stratify BC according to aggressiveness independently from the sites and type of metastases, both in the IBC and nIBC subgroups. IBC has a distinctive CTCs/ctDNA-based signature, in particular ctDNA-low pts have a lower incidence of HER2 positive CTCs and CTC clusters. This signature is probably due to predominant lymphatic metastatic spread and aggressive phenotype.
How is inflammatory breast cancer (IBC) different? Integration of clinico-pathological features and circulating tumor cells (CTCs)-based biomarkers for disease and prognostic assessment

Lorenzo Gerratana¹, Qiang Zhang¹, Chun Wang², Ami Shah¹, Andrew A Davis¹, Zhong Ye³, Youbin Zhang¹, Maysa Abu-Khalaf³, Lisa Flaum¹, Kimberly Strickland³, Giovanna Rossi³, Amir Behdad¹, William Gradishar¹, Leonidas Platanias¹, Hushan Yang³ and Massimo Cristofanilli¹. ¹Robert H. Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL; ²University of Udine, Udine, Italy; ³Thomas Jefferson University, Philadelphia, PA and ⁴Ospedale dell'Angelo – Ospedale SS. Giovanni e Paolo, Venezia, Italy.

Background: Since IBC is rare and burdened by a particularly unfavorable prognosis, biomarkers able to enhance diagnosis and risk assessment are of pivotal importance and a current unmet need. The aim of this study is to integrate standard clinico-pathological features with CTCs-based biomarkers for a more objective and detailed characterization of IBC.

Methods: This study analyzed retrospectively 251 Advanced Breast Cancer (BC) patients (pts) longitudinally characterized for CTCs and CTCs-based biomarkers at Thomas Jefferson University (Philadelphia, PA) and Northwestern University (Chicago, IL). CTCs were enumerated through the CellSearch system (Menarini Silicon Biosystems), and characterized for HER2 expression using the CellSearch CXC Kit. Pts were defined as stage IV aggressive based on the previously reported ≥5 CTCs cut-off (Davis et al. 2018). Associations between clinical features, CTC-derived biomarkers and IBC were tested through uni and multivariate logistic regression. Survival was tested though log-rank test.

Results: Within the analyzed cases, 46% were diagnosed with IBC and among them, 38% was stage IV aggressive. CTC clusters (CTC_CL) were detectable in 12.5% of pts and HER2 positive CTCs (HER2_CTC) in 29.5%. Notably, IBC patients (pts) had a significantly lower CTC count with respect to non-IBC (median 2.5 vs 0 respectively for non-IBC and IBC; P=0.019). BC subtype (HER2 positive BC: OR 2.97; Triple negative BC: OR 2.13), liver and bone involvement (liver: OR 0.46; bone involvement: OR 0.31) were the only significant clinico-pathological features associated with IBC at univariate logistic regression. Interestingly, a marginal significance was observed for soft tissue involvement (OR 1.65, 95%CI 0.95 - 2.87, P=0.07). Stage IV aggressive and presence of HER2_CTC at baseline were moreover inversely associated with IBC. The multivariate model confirmed the significant association between IBC and HER2 positive BC subtype (OR 2.64, 95%CI 1.08 - 6.48, P=0.034), absence of bone involvement (OR 0.31, 95%CI 0.14 - 0.68, P=0.003) and absence of HER2_CTC (OR 0.38, 95%CI 0.15 - 0.98, P=0.045). The baseline detection of CTC_CL was a strong predictor of prognosis for OS in IBC pts (median OS (mOS) 7.6 months (mts) vs not reached (NR) respectively for detectable vs non-detectable CTC_CL; P<0.0001), while a trend was observed for HER2_CTC (mOS 9.9 mts vs NR respectively for detectable vs non-detectable HER2_CTC; P<0.082). Pts negative for CTC_CL at baseline had higher odds of developing CTC_CL in later time-points if stage IV aggressive (OR 12.27, 95%CI 2.10 - 71.57, P=0.005). Despite no baseline factors were significantly associated with the onset of HER2_CTC in later time-points, a trend (P=0.05) was observed for patients without lymph node involvement (OR: 5) and with bone involvement (OR: 4.3).

Conclusion: HER2_CTC and in particular CTC_CL are promising prognostic predictors in IBC. Stage IV aggressive IBC pts could benefit from a longitudinal CTCs assessment, being more prone to develop CTC_CL and therefore at higher risk of rapid disease progression. Probably due to the tropism for soft tissue, IBC is characterized by a lower number of HER2_CTC.
Metastatic inflammatory breast cancer: Clinical features and outcomes in the national, multicentric, real-life ESME cohort

Background: Primary inflammatory breast cancer (IBC) is a rare and aggressive form of breast cancer. Survival of IBC patients has been improved by multimodal therapy. However, 5-year overall survival (OS) still remains close to 50-60%, due to high risk of disseminated disease. Given the low incidence, prognosis of metastatic cases stages is poorly described.

Methods: This study aimed to describe OS of IBC (T4d AJCC TNM classification) with upfront or recurrent metastatic disease compared with non-IBC patients in the ESME database (N=16,702 patients). OS was calculated from the diagnosis of metastasis to the date of death (from any cause), or censored to date of latest news. Secondary objectives included progression-free survival (PFS).

Results: From 2008 to 2014, 7,465 patients with diagnosis of MBC and known clinical status of their primary tumor (T) were identified, including 582 IBC (T4d) and 6,883 non-IBC. As expected, metastatic IBC was associated with pejorative features compared to non-IBC, with less hormonal receptors-positive tumors (44% vs 65.6%), more HER2-positive (30% vs 18.6%) or triple-negative (25.9% vs 15.8%) cases (p<0.001), more frequent upfront M1 stage (53.3% vs 27.7%; p<0.001), and shorter median disease-free interval (2.02 years vs. 4.9 years; p<0.001). With a median follow-up of 50.2 months (0-104), median OS was 28.4 [95%CI 24-33.8] versus 37.2 months [95%CI 36.1-38.5] in metastatic IBC and non-IBC cases respectively (p<0.0001, log-rank test). By multivariate Cox model with adjustment for major prognostic factors [including age, disease-free interval, type of relapse, visceral metastases, molecular subtype, grade], OS was significantly shorter in the metastatic IBC group compared with non-IBC group (HR 1.15 [95%CI 1-1.3], p=0.0050). Of note, survival of metastatic IBC patients improved over the last years: median OS 24 months [95%CI 20-31.9], 29 months [95%CI 21.7-39.9] and 36 months [95%CI 27.9-NE] if diagnosed before 2011, between 2011 and 2012, or after 2012 respectively (p=0.003). Such improvement was not observed in non-IBC patients. IBC was associated with shorter median PFS under first line systemic treatment compared with non-IBC (7.2 months [95%CI 6.6-8.3] vs 9.5 months [95%CI 9.1-9.8] respectively, p=0.0136). This was maintained in a multivariate Cox model adjusting for same factors as for OS (HR 1.15 [95%CI 1-1.3], p=0.0050).

Compared with non-IBC, synchronous metastatic IBC showed worse median OS and PFS (39.9 months [95%CI 34.2-45.3] vs 48.4 months [95%CI 46.3-50.8], p=0.0035; 10 months [95%CI 8.8-12.7] vs 14.5 months [95%CI 13.6-15.7], p=0.0027, respectively. Similar results were obtained in metachronous metastatic cases (20.01 months [95%CI 17.1-21.2] vs 32.8 months [95%CI 31.5-34.3], p<0.0001; 5.1 months [95%CI 4.1-6] vs 7.9 months [95%CI 7.6-8.3], p<0.0001, respectively).

Conclusion: In this large national and multicentric study, IBC is a major and independent factor associated with adverse outcome in metastatic setting. Of note, the independent adverse impact on PFS identified in this study may suggest a lower sensitivity of metastatic IBC to available therapeutics. However, results seem to improve in the last years. Detailed analysis according to phenotype will be available.
Outcome of triple negative inflammatory breast cancer (TNIBC) treated with dose-dense dose intense neoadjuvant chemotherapy (NAC), prognostic impact of post NAC lymphovascular invasion and tumor infiltrating lymphocytes (TIL)

Luca Campedel¹, Asker Binasker¹, Paul Blanc-Durand¹, Stephanie Becourt¹, Florence Ledoux¹, Caroline Cuvier¹, Charlotte Gardnair¹, Luis Teixeira¹, Anne de Roquancourt¹, Marc Espie¹ and Sylvie Giacchetti¹. ¹APHP Hôpital Universitaire Saint-Louis, Paris, France.

Background
Inflammatory breast cancers (IBC) particularly triple negative (TN) subtype have poor prognosis. There are few series reporting IBC outcome according to their immunohistochemical profile. We have already shown the efficiency of dose dense dose intense chemotherapy in triple negative breast cancer (1). We report a series of TNIBC treated with dose dense anthracycline cyclophosphamide followed with taxane and analyzed the correlation between pathological complete response (pCR), pre and post NAC TIL, post NAC LVI and disease free survival (DFS).

Methods
Between January 2010 and December 2016, all patients with TNIBC seen at breast cancer disease center, St Louis hospital, Paris, France, were treated with neoadjuvant dose dense dose intense Cyclophophamide (1.2g/m² d1) - Epirubicin (75mg/m² d1) q2w (SIM regimen) followed with 12 injections of paclitaxel (80 mg/m2) qw or 4 injections of docetaxel (100 mg/m2) q3w. All patients have histologically proven TN tumors and no evidence of metastases assessed by initial FDG PET Scanner. Mastectomy and axillary clearance was performed after chemotherapy. pCR was defined as no residual invasive tumor in breast and lymph nodes. TIL and lymphovascular invasion were evaluated pre and post NAC by 2 independent anatomopathologists dedicated to breast cancer. Delta TILS was defined as the difference between post chemotherapy and pre chemotherapy TIL.

Results
Thirty TNIBC pts were treated, 28 underwent surgery and 2 progressed during chemotherapy. Median follow-up was 39 months (8 – 86). 9/30 patients (30%) achieved pCR. Median disease free survival (DFS) was 41 months (2 – 86). Median TIL infiltration at diagnosis was 11% (0-60) and dropped to 1% after chemotherapy (0 – 80). Median delta TIL was - 9% (-50% – +40%). TIL increase after chemotherapy was associated with a decrease of DFS (14 months vs not reached ; p = 0.0009). LVI was present on surgical specimens in 12 cases (12/30, 43%; 12/21 non pCR pts 57 %). Presence of LVI after chemotherapy was significantly associated with a decrease of DFS in the whole population (21 months vs not reached ; p = 0.008) and no significantly among the patients without pCR (23 months vs not reached; p = 0.07).

Conclusion
To the best of our knowledge, it is the best pCR rate reported in TNIBC (2). We showed in this retrospective series of 30 TNIBC that dose dense dose intense chemotherapy is efficient in this population. Presence of lymphovascular invasion and TIL after neoadjuvant chemotherapy in TNIBC are strong prognostic factors associated with DFS. Systematic determination of post NAC TIL and LIV could be a surrogate to propose adjuvant treatment after NAC in TNIBC.

Immune modulation with humanized anti-EGFR antibody panitumumab in an immunocompetent mouse model for inflammatory breast cancer

Xiaoping Wang, Shan Shao, Troy Pearson, Yating Cheng, James M Reuben, Debu Tripathy and Naoto T Ueno.

The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Inflammatory breast cancer (IBC) is the most lethal and aggressive form of breast cancer and there are no approved targeted therapies specifically for IBC. Targeting the epidermal growth factor receptor (EGFR) pathway is a promising therapeutic target for patients with triple-negative IBC (TN-IBC) with a reported pathological complete response rate of 42% (JAMA Oncology, 2018). The tumor microenvironment (TME) is a critical contributor to the aggressiveness of IBC. Delineating cross-talk between EGFR-targeted therapies and TME components, which define IBC, could inform more efficient combination regimens and novel clinical trial designs for IBC. However, such studies have not been conducted due to the lack of a syngeneic IBC mouse model. Here we report the establishment of an IBC immunocompetent mouse model and the effects of panitumumab (PmAb) on IBC tumor growth and the TME.

Methods: TN-IBC cell lines, SUM149 or FC-IBC-02, were mixed with 50% Matrigel and inoculated into mammary fat pads of hu-NSG-SGM3 mice engrafted with hematopoietic stem cells (The Jackson Laboratory). SUM149 tumor growth in hu-NSG-SGM3 mice treated with either IgG2 (isotype control, 4 mg/kg) or PmAb (1 mg/kg and 4 mg/kg) was measured. The percentages of TME components, including human CD4+ T, CD8+ T, regulatory T (Tregs), and natural killer (NK) cells, and M1 or M2 macrophages, in the peripheral blood and tumor tissues treated with IgG2 and PmAb for 7 weeks were measured by flow cytometry.

Results: Hu-NSG-SGM3 mice supported the growth of TN-IBC SUM149 and FC-IBC-02 xenografts. These humanized mouse models were named SUM149-huSGM3 and FC-IBC-02-huSGM3, respectively. Analysis of the blood cells showed that SUM149-huSGM3 mice display human CD4+ T, CD8+ T, Tregs, M1 and M2 macrophages. T cell infiltration and M1 and M2 macrophages were also detected in SUM149-huSGM3 tumors. NK cells were not detected in both peripheral blood and tumors. PmAb treated SUM149-huSGM3 mice had significantly reduced SUM149 tumor growth, compared with mice that received the IgG2 control. PmAb treatment increased the percentage of CD8+ T cells and reduced the percentage of Tregs in peripheral blood. A similar analysis of tumor infiltrating lymphocytes isolated from each group showed an increase in percent CD8+ T cells in mice treated with PmAb. There were no significant changes of M1 or M2 macrophages following PmAb treatment. These results suggest that the increase in percentage of CD8+ T cells in peripheral blood and IBC tumors, and the decrease in percentage of Tregs in peripheral blood may contribute to the therapeutic efficacy of PmAb.

Conclusion: We established the first immunocompetent mouse model to study the TME and immune response in IBC, which provides the premise for conducting a diversity of novel preclinical therapeutic studies. The mechanism of how immune responses of TN-IBC xenografts mediates the therapeutic efficacy of PmAb in IBC tumors needs to be further investigated. Our study also suggests that combination therapy with immune checkpoint inhibitors may potentiate the efficacy of anti-EGFR therapy in IBC. The therapeutic efficacy of PmAb and anti-PD-L1 combination in SUM149 humanized mice is in progress.
Risk of contralateral breast cancer (CBC) in women with ductal carcinoma in situ (DCIS) with and without synchronous lobular carcinoma in situ (LCIS)

Megan E Miller¹, Shirin Muhsen², Emily C Zabor², Jessica Flynn², Cristina Olcese², Dilip Giri², Kimberly J Van Zee² and Melissa Pilewskie². ¹Case Western Reserve University, University Hospitals, Cleveland, OH and ²Memorial Sloan Kettering Cancer Center, New York, NY.

Background: LCIS is considered a risk factor for bilateral breast cancer, but the effect of LCIS diagnosed concurrently with DCIS is not known. We sought to compare CBC and ipsilateral breast tumor recurrence (IBTR) rates in women with DCIS with and without synchronous LCIS treated with breast conserving surgery (BCS).

Methods: A prospectively maintained database of DCIS patients undergoing BCS from 2000-2011 was used to identify women with a contralateral breast at risk. Patients with synchronous ipsilateral LCIS found at core needle biopsy or surgical excision were included in the “DCIS + LCIS” group; those with contralateral or bilateral LCIS were excluded. Associations of patient, tumor, and treatment factors with CBC and IBTR were evaluated using logistic regression.

Results: Of the 1888 patients identified, 1475 (78%) had DCIS only and 413 (22%) had DCIS with synchronous LCIS. Median follow-up was 7.5 years (range 0-17 years). 305 patients had a subsequent breast event; 216 IBTR and 89 CBC.

The 5 and 10-year cumulative incidence of IBTR was similar in both groups: 6.3% and 14.4% for DCIS only, compared with 5.9% and 14.0% for DCIS + LCIS (p = 0.94), respectively. The 5 and 10-year cumulative incidence of CBC was significantly greater in the DCIS + LCIS group: 5.7% and 10.0%, compared with 2.4% and 5.0% for DCIS only (p < 0.001).

Table 1 summarizes uni-and multi-variable analyses of risk factors associated with CBC and IBTR among women with DCIS treated with BCS.

Table 1: Risk factors associated with CBC and IBTR in patients with DCIS treated with BCS

*p < 0.05
After adjustment for other factors, CBC risk was more than 2-fold higher in the DCIS + LCIS group compared with the DCIS only group (HR 2.37, 95% CI 1.54-3.65, p < 0.001). There was no difference in IBTR risk based on presence of synchronous LCIS. Younger age and receipt of endocrine therapy were significantly associated with decreased risk of CBC.

**Conclusions**: LCIS diagnosed concurrently with DCIS is not associated with IBTR, but increases the risk of CBC two-fold. Endocrine therapy should be considered both for the index DCIS and for prevention of subsequent CBC.
A quantitative centrosomal amplification score (CAS) predicts local recurrence in ductal carcinoma in situ

Karuna Mittal¹, Jaspreet Kaur¹, Guanhao Wei¹, Michael Shawky Toss², Remus M Osan³, Emiel AM Janssen³, Håvard Søiland³, Emad A Rakha², Padmeshree CG Rida¹,⁴ and Ritu Aneja¹. ¹Georgia State University, Atlanta, GA; ²University of Nottingham and Nottingham University Hospitals, Nottingham, United Kingdom; ³University of Stavanger and Stavanger University Hospitals, Stavanger, Norway and ⁴Novazoi Theranostics, Inc, Rolling Hills Estates, CA.

Background: About 60-80% of ductal carcinoma in situ (DCIS) cases are high-grade (HG) DCIS with an elevated risk of local recurrence (LR) even after a lumpectomy. Patients are often under or over treated due to the lack of accurate recurrence risk prediction models. Current prognostic models such as OncotypeDX and Van Nuys Prognostic Index (VNPI) lack consistency and are limited to a specific subset of patients. Here in this study, we show that the extent of centrosome amplification (CA) in a DCIS lesion can predict the risk of LR after lumpectomy. CA refers to presence of supernumerary or large centrosomes and is a characteristic of pre-invasive lesions, and breast tumors, and promotes erroneous mitoses and chromosomal instability.

Methods: We have pioneered a semi-automated pipeline that integrates immunofluorescence confocal microscopy with digital image analysis and yields a quantitative Centrosomal Amplification Score (CAS) for each patients' tumor sample by evaluating severity and frequency of centrosomal aberrations therein. To this end, we first immunofluorescently stained centrosomes in formalin fixed paraffin embedded resection samples from DCIS patients (discovery cohort n=133 and a validation cohort n=119) using an antibody against γ-tubulin, and co-stained nuclei with DAPI. Next, we imaged the slides and processed the raw 3D image data using IMARIS Biplane 8.2 3D volume rendering software. Finally, we calculated centrosome numbers and volume in ~250 cells from each patient sample. Using a mathematical algorithm, we generated a composite CAS score for each patient sample by integrating the numerical (CASi) and structural (CASm) aberrations.

Results: We found that DCIS patients with recurrence exhibited higher CAS. Intriguingly, higher CAS was also associated with greater risk of developing ipsilateral breast events [Hazard ratio (HR) =7.58 for discovery cohort and HR=5.8 for validation cohort, p<0.0001] which remained significant (HR=8.5 for discovery and HR=3.39, p<0.0001) after accounting for the confounding factors like age, tumor size, comedo necrosis and radiotherapy. Kaplan Meir survival analysis indicated that high CAS was associated with poor recurrence-free survival (RFS) (p<0.001). For the high and low CAS groups, the 5-year risk of recurrence was 87.5% and 12.5% respectively (p<0.001). In our discovery cohort, a head-to-head comparison of the ability of VNPI and CAS to predict recurrence illuminated that CAS was able to stratify the DCIS group in recurrence and recurrence-free group with much higher significance (p<0.0001) than the Van Nuys Prognostic Index (VNPI) (HRs for CAS- 8.8 vs. VNPI 0.959). Finally, the Harrell's concordance index using SAS PROC PHREG tests yielded that the probability of a patient with poorer/lower RFS to be in the high CAS group is 76.2%.

Conclusion: Our data compellingly show that CAS quantifies the risk of recurrence in DCIS patients with the highest concordance and provides a novel and innovative tool to tailor their treatment based on their risk profile.
A predictive model for local recurrence in patients treated for ductal carcinoma in situ of the breast (DCIS)

Carlos Martinez-Perez¹, Arran K Turnbull¹, Anu Fernando¹, Gregory E Ekatah², Laura M Arthur¹, Christopher WJ Cartlidge², Neil Johns², Andrew H Sims¹, Jeremy S Thomas¹ and J Michael Dixon². ¹Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom and ²Edinburgh Breast Unit, Western General Hospital, Edinburgh, United Kingdom.

Background: Ductal carcinoma in situ (DCIS) is a heterogeneous precursor, non-invasive breast lesion. There is a lack of specific DCIS molecular predictors of in breast tumour recurrence (IBTR) or progression to invasive breast cancer (IBC) after breast conserving surgery (BCS) +/- radiotherapy (RT). The aim of this was to identify novel biomarkers and combine these with clinical parameters to develop a new model to predict IBTR in patients treated by BCS for DCIS.

Methods: A single institution DCIS biomarker discovery study included a case-control matched series of 180 patients (median age 61, range 35-94) treated at the Edinburgh Breast Unit between 2000 and 2010:
· 88 patients with low/intermediate grade DCIS treated with BCS alone; 18 recurred within 10 years.
· 92 patients with high grade DCIS treated by BCS and RT; 22 recurred within 10 years.
Median follow-up was 7.4 years. RNA was extracted from DCIS lesions and whole-genome transcriptomics analysis was performed using Lexogen QuantSeq. Predictive models were generated based upon the most informative genes. Independent validation cohorts are also available and are currently being used for validation.

Results: The models developed predict risk of IBTR in patients with low or intermediate grade DCIS treated with BCS alone and high grade DCIS treated with DCIS plus RT. The models were found to be independent of grade and stratify patients into binary groups of high and low risk of recurrence.
A promising model was developed based on the expression of 5 genes combined with tumour diameter ≤15mm or >15mm.
• In low/intermediate grade DCIS expression levels of a solute carrier family gene, kinetochore associated gene and an immunomodulatory gene are predictive of recurrence.
• In high grade DCIS an additional solute carrier and a glutathione S-transferase related gene are predictive of recurrence.
• In the training sets the models have 96% (high-grade) and 92% (low/intermediate grade) accuracy of prediction of subsequent recurrence and estimates of IBTR-free survival were highly significant in both groups (<0.0001). Validation of the model by RT-PCR and immunohistochemistry is underway in both the training cohort and an independent validation cohort.

Conclusions:
· Promising models to predict risk of IBTR in patients treated for DCIS have been developed.
· Novel biomarkers that predict recurrence have been identified using new technologies that may have clinical potential.
· Independent validation is currently underway.
HER2 overexpression in ductal carcinoma in situ: A biomarker for risk stratification and therapeutic implication

Jun Yin¹, Philippe Gascard², Brittany Last¹, Maharaj Singh¹, Thea Tlsty² and Judy A Tjoe¹³. ¹Aurora Research Institute, Milwaukee, WI; ²University of California, San Francisco, San Francisco, CA and ³Aurora Health Care, Milwaukee, WI.

**Background:**
After initial treatment for ductal carcinoma in situ (DCIS), a subsequent clinically significant event (SCSE) such as another diagnosis of DCIS, atypia or invasive breast cancer (IBC), will likely lead to further surgical/medical therapy. Pathologically, DCIS is treated on the basis of estrogen (ER) and progesterone receptor (PR) status with hormonal therapy (HT), ie, tamoxifen (TMX) or aromatase inhibitor, regardless of human epidermal growth factor receptor (HER2) overexpression. Although HER2 is a well-established prognostic marker for IBC, the role of HER2 in DCIS is less appreciated. Recent studies have documented the prognostic value of p16, COX-2 and Ki67 as prognostic biomarkers for locoregional invasive recurrences due to abrogated response to cellular stress (ARCS). Notably, a high-risk population of DCIS patients lacking ER expression but over-expressing HER2, p16 and COX-2 has been recently identified. In the present study, we compared expression levels of HER2 and the 3 ARCS markers in a large cohort of DCIS patients treated with contemporary standard of care and with >5-year follow-up to assess their association with cancer progression and predictive value for developing a SCSE.

**Methods:**
Formalin-fixed paraffin-embedded tissue sections from 99 patients diagnosed with primary DCIS(1999-2013) were stained for ER, PR and HER2 expression by immunohistochemistry (IHC). If equivocal, HER2 amplification was assessed by Silver In Situ Hybridization. An additional slide was stained for p16, Ki67 and COX-2 using a novel multiplex IHC strategy. Quantification of the 3 ARCS markers' expression in both epithelial and stromal compartments was carried out using a software (Inform™)-guided approach. For expression level comparison of the three markers between HER2+ and HER2- DCIS, Wilcoxon-Mann-Whitney test was used. Fisher's exact or Chi-square test was used for other data analysis.

**Results:**
Simultaneous increase in epithelial p16, COX-2 and Ki67 expression in DCIS lesions was associated with subsequent IBC progression. HER2+ DCIS was significantly associated with high grade (p=0.0014), comedo-necrosis subtype (p=0.0022) compared to HER2- lesions. Upregulation of stromal COX-2 and p16 was significantly (p=0.008) associated with progression to SCSE in HER2- DCIS. The majority (5/6, 83%) of HER2+ DCIS patients treated with HT developed a SCSE, while only 22% (6/27) of HER2- DCIS patients treated with HT developed a SCSE. COX-2 upregulation was significantly associated with resistance to HT in HER2+ DCIS patients.

**Conclusion:**
High expression of p16, COX-2 and Ki67 in DCIS lesions can serve as powerful predictive biomarkers for DCIS progression to IBC. Our preliminary data suggest that overexpression of stromal p16 and COX-2 may help predict SCSEs in HER2- DCIS. Additionally, assessment of HER2 expression in DCIS may allow identification of patients who would not benefit from traditional HT as HER2 overexpression may predict TMX resistance. Since our data suggest that TMX resistance in HER2+ DCIS may be linked to upregulation of COX-2, one may propose that COX-2 inhibitors in conjunction with TMX may minimize TMX resistance in HER2+ DCIS. These preliminary data will need to be reproduced in a larger cohort to solidify their significance.
Clinicopathological characteristics and prognosis of young patients with ductal carcinoma in situ

Akina Seki¹, Naoko Matsuda¹, Yuka Kajiura¹, Daiki Kobayashi², Naoki Hayashi¹, Hiroko Tsunoda¹, Koyu Suzuki¹, Atsushi Yoshida¹, Junko Takei¹ and Hideko Yamauchi¹. ¹St.Luke's International Hospital, Tokyo, Japan and ²Center for Clinical Epidemiology, St. Luke's International University, Tokyo, Japan.

**Background:** The peak age at diagnosis of breast cancer differs between patients in Asian countries (40 - 50 years), and those in Western countries (60 - 70 years). With the increasing use of screening mammography, the incidence of ductal carcinoma in situ (DCIS) has increased significantly in younger Asian women. Nevertheless, our knowledge of the clinicopathological features and prognosis in young patients with DCIS is relatively limited. We aimed to compare the clinicopathological features of younger patients with that of older patients with DCIS and to evaluate their prognostic factors.

**Methods:** A total of 1445 women were diagnosed with DCIS between the years 2005 and 2015. Patients with the past history of breast cancer and managed without surgery were excluded. The young age group included patients <50 years of age, whereas the old age group included patients ≥50 years of age at diagnosis. We compared the clinicopathological characteristics [tumor size, surgery type, estrogen receptor (ER) and progesterone receptor (PgR) status, HER2 status, nuclear grade, margin status, radiotherapy, endocrine therapy, family history of breast cancer, and screening presentation or presentation with symptoms] and prognosis [disease-free survival (DFS), and overall survival (OS)] between the groups. DFS included the following events: contralateral breast cancer, loco-regional, and distant recurrences. DFS and OS were estimated using the Kaplan–Meier method. The risk factors associated with events were estimated using the log-rank test for univariate analysis. *P* values < 0.05 were considered statistically significant.

**Result:** Among the 1445 patients diagnosed with DCIS, 1281 were included in this study. The median age at diagnosis was 47 years (range, 22-87 years). The median follow-up time was 72 months (range, 1-162 months). ER and/or PgR status was positive in 1133 patients (88%). HER2 status was positive in 289 patients (23%). Premenopausal status was noted in 867 patients (68%). The median tumor size was 3.0 cm. Of 1281, 202 (18%) patients received endocrine therapy, 846 (66%) received breast conserving surgery, and 724 (86%) received radiation therapy. There were 765 patients (60%) in the young group. Significantly more patients in the young group had low nuclear grades, were ER and/or PgR positive, were HER2 receptor negative, underwent mastectomy, presented with symptoms, and had close/positive margins. Fifty-eight (4.5%) events occurred: 41 (3.2%) contralateral breast cancers, 19 (1.5%) loco-regional recurrences, and one (0.1%) distant metastasis. No death due to breast cancer was reported. On multivariate analysis, the young group (hazard ratio: 2.24, 95% CI: 1.01 - 4.95, *P* = 0.04), and presentation with clinical symptoms (hazard ratio: 2.09, 95% CI: 1.07-4.10, *P* = 0.03) significantly correlated with worse DFS. OS was not significantly different between the groups.

**Conclusion:** This was the largest study with young patients with DCIS in the Asian population. We found that age at diagnosis was a significant independent factor associated with DFS. While genetic background also requires consideration, women with DCIS at <50 year of age may require intensive surveillance. This result requires confirmation with longer follow-up.
Defining molecular signatures to personalise management of patients with early breast cancer

Natalie Allen¹, Michael Allen¹, Khariyia Ahmed¹, Jenny Gomm¹, Rachel Nelan¹, Ai Nagano¹, Claude Chelala¹, Emanuela Gadaleta¹, Mangesh Thorat², Jack Cuzick² and Louise J Jones¹. ¹Barts Cancer Institute, London, United Kingdom and ²Wolfson Institute of Preventative Medicine, London, United Kingdom.

Background

A review of breast screening highlighted the need to reduce overdiagnosis. Ductal Carcinoma In-Situ (DCIS) contributes significantly to this overdiagnosis. Epithelial cells in DCIS are as genetically advanced as those in invasive disease, focusing attention on the tumour microenvironment (ME). A key components of the ME in DCIS is the myoepithelial cell(MEC). These cells lie at the interface of the epithelial and stromal compartments, regulating cell function. We previously have identified changes in the MEC that contribute to tumour progression. Here we investigate the functional and clinical significance of a novel change in MEC phenotype: loss of Galectin-7 (Gal-7) expression. Gal-7 is proposed to play a role in apoptosis. We hypothesise that changes in MEC phenotype in DCIS alter the ME towards a pro-invasive phenotype, and hypothesise that loss of Gal-7 modifies the ME, destabilizes the MEC interface and ultimately may lead to loss of the MEC population through apoptosis.

Methods

Gal-7 expression and function was investigated in clinical samples and in-vitro model systems, respectively. Gal-7 expression was assessed in a series of pure DCIS samples (low risk model) and DCIS with co-existant invasion (high risk model). Tissue sections were stained for Gal-7 and MEC expression scored on a duct-by-duct basis as positive, heterogeneous or negative.

An in-vitro model of normal primary myoepithelial cells isolated from reduction mammoplasty was used to investigate the functional impact of loss of Gal-7. These cells have high endogenous levels of Gal-7. Gal-7 was knocked down using siRNA and apoptosis assessed using cleaved caspase-3. The effect of Gal-7 on MEC layer integrity was assessed using immunofluorescence and adhesion assays.

The global impact of loss of Gal-7 was investigated using RNA sequencing.

Results

In the tissue analysis 1926 DCIS ducts were scored for MEC expression of Gal-7. Significantly more ducts showed loss of Gal-7 in DCIS with co-existant invasion, with pure DCIS showing 388 ducts positive and DCIS with invasion 144 DCIS ducts positive (p=0.0014). Pure DCIS and DCIS with invasion had 99 and 646 negative DCIS ducts respectively (p=0.0002).

In model systems of primary MEC, knockdown of Gal-7 resulted in increased expression of cleaved caspase-3, suggesting lower levels of Gal-7 increases apoptosis. In functional assays silencing Gal-7 reduces adhesion to both fibronectin and laminin extracellular matrices (p-value 0.005 and 0.001 respectively)

RNA sequencing indicates silencing Gal-7 increases LOX expression - a key regulator of the collagen matrix of the microenvironment.

Conclusion

Normal MEC strongly express Gal-7. Expression is lost in DCIS, with significantly more frequent loss in DCIS with co-existant invasion, suggesting that loss is associated with a more advanced phenotype. Functional assays indicate that loss of MEC Gal-7 enhances MEC apoptosis, which may be one mechanism by which this interface is lost during progression. Gal-7 negative MEC also show impaired adhesion to matrix proteins and lead to up-regulation of LOX, an enzyme key in promoting tumourigenesis. The incorporation of Gal-7 expression into a risk stratification algorithm has functional evidence and is currently being investigated.
Performance of Oncotype DX DCIS score across diverse ethnic populations

Priyanka Mittar1, Sara Casella3, Alessandro Bombonati1, Oluwadunni Emiloju1, Lisa Jablon1, Delray Schultz2, John C Leighton1 and Lawrence J Solin1. 1Einstein Healthcare Network, Philadelphia, PA; 2Millersville University, Millersville, PA and 3Policlinico Tor Vergata, University of Rome, Rome, Italy.

There is a paucity of data on Oncotype DX DCIS Score and ethnic variation. It has been postulated that there are different molecular features /drivers among different ethnic populations. The Oncotype DX DCIS Score is a genomic test designed to analyze the expression of a group of 12 genes which can quantify 10-year local recurrence risk after surgery. The purpose of this study is to evaluate diverse ethnic patients with DCIS relative to traditional clinical pathologic factors and Oncotype DX DCIS Score.

We analyzed consecutive cases of DCIS from 2011-2017 who underwent Oncotype DX DCIS Score testing at a single institution. Eighty-four female patients were divided into 5 groups based on self-reported ethnicity: White (36%), African American (AA) (48%), Asian (8%), Hispanic (4%) and Other (4%). Clinical and traditional pathologic factors were collected including age, nuclear grade (NG), ER/PR status and Oncotype DX DCIS Score. The distribution of NG and Oncotype DX DCIS Score was analyzed across ethnic groups.

The mean age at diagnosis was 63. Overall 99% of cases were hormone positive. Comparison of White and AA patients revealed a correlation between ethnic group and DCIS Score, with a p value of 0.0087 (Table 1). Similarly, we looked at all five ethnic groups and Oncotype DX DCIS Score and found a p value of 0.022. We evaluated ethnicity with White and AA patients versus NG and obtained a p value of 0.084 (Table 2). In addition, we assessed all five ethnic groups and NG. We obtained a p value of 0.068. No AA patients with DCIS had a high DCIS Score. No patients with low NG DCIS had a high DCIS Score.

Analysis of the three factors (NG, ethnicity and DCIS Score) concurrently showed that they are not independent. In summary, our study provides valuable data on Oncotype DX DCIS Score and NG across a diverse patient population. These data highlight the importance of incorporating both traditional clinical pathologic factors and DCIS Score molecular testing for making treatment decision across different ethnic patient populations.

BHLHE40-AS1 is an enhancer associated long noncoding RNA critical to breast cancer progression

Rebecca S DeVaux¹, Hanna Schimjawicz², Cristian Coarfa³, Fariba Behbod⁴ and Jason I Herschkowitz¹. ¹Cancer Research Center, University at Albany State University of New York, Albany, NY; ²Queens University, Kingston, ON, Canada; ³Baylor College of Medicine, Houston, TX and ⁴University of Kansas Medical Center, Kansas City, KS.

Increased emphasis on breast cancer screening has led to a dramatic increase in diagnosis of ductal carcinoma in situ (DCIS). DCIS lesions are nonobligate precursors of invasive ductal carcinoma (IDC) and thus, the current standard-of-care is aggressive therapy to prevent invasive and metastatic disease. However, only ~40% of DCIS cases are predicted to progress leading to a current state of overtreatment and overdiagnosis. Thus, there is a critical need to identify functional determinants of progression of DCIS to IDC to allow discrimination between indolent and aggressive breast cancers and refine patient treatment strategies. We propose that long noncoding RNAs (lncRNAs) functionally drive breast cancer progression and their expression can discriminate between innocuous and potentially invasive DCIS.

Using biopsies from women with tandem DCIS and IDC lesions, we identified 35 lncRNAs whose expression can distinguish between pre-invasive and invasive disease. From this candidate list, the lncRNA BHLHE40-AS1 is found enriched in multiple breast cancer progression models, in HER2+ cell lines, and HER2+ patient tumors. Functionally, BHLHE40-AS1 is found to support tumor cell cycle and motility and may serve as a clinically relevant biomarker and therapeutic target in invasive breast cancer.

Further, BHLHE40-AS1 is expressed from a known super-enhancer that preliminary evidence suggests undergoes altered chromatin looping during breast cancer progression. Interestingly, over half of the candidate lncRNAs are associated with enhancer regions. Current studies are investigating super-enhancers, and associated lncRNAs that become acquired during breast cancer progression.
Prognostic impact and possible pathogenesis of lymph node metastasis in ductal carcinoma in situ of the breast

Rika Yonekura¹,², Tomo Osako¹,², Takuji Iwase¹, Akiko Ogiya¹, Takayuki Ueno¹, Shinji Ohno¹ and Futoshi Akiyama¹,². ¦ The Cancer Institute Hospital of the Japanese Foundation for Cancer Research, Tokyo, Japan and ¦ The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Japan.

Background: By definition, ductal carcinoma in situ (DCIS) does not metastasize to the lymph nodes. However, since the introduction of molecular whole-node analysis using the one-step nucleic acid amplification (OSNA) assay for sentinel node (SN) biopsies, the number of DCIS patients with SN metastasis has increased. The clinical management of node-positive DCIS remains controversial because these patients can be treated as different stages based on the pathogenesis: e.g. occult invasive cancer with true nodal metastasis (T1N1) or true DCIS with iatrogenic dissemination of benign or tumor cells into lymph node (TisN0). In this retrospective cohort study, we aimed to elucidate the pathogenesis of nodal metastasis in DCIS and the clinical management of node-positive DCIS.

Patients and Methods: Subjects comprised of 427 patients with a routine postoperative diagnosis of DCIS who underwent SN biopsy using the OSNA assay between 2009 and 2012. The cut-off values of the OSNA assay for negative/positive results and micro/macrometastasis were defined at 250 and 5,000 copies/µL of cytokeratin 19 mRNA, respectively. In the SN-positive patients, all paraffin blocks containing the primary tumor were step-sectioned with 0.5-mm intervals until the tissue was exhausted, and all microscopic slides were examined for detecting occult invasions. Afterwards, the patients were classified into three cohorts based on the SN status and occult invasion: (1) no SN metastasis (TisN0), (2) SN metastasis without occult invasion (TisN1), and (3) SN metastasis with occult invasion (T1N1). Tumor characteristics including risk factors of occult invasions (e.g. large size, comedo-type), prognosis, and SN and non-SN status were compared among the three cohorts. The median follow-up time was 73.6 months.

Results: Of the 427 patients, 408 (95.6%) were SN-negative and 19 (4.4%) were SN-positive. By examining a total of 1,421 step-sectioned slides, 9 of the 19 SN-positive patients had occult invasions in the primary tumors. Overall, 408 (95.6%), 10 (2.3%), and 9 (2.1%) were classified into the TisN0, TisN1, and T1N1 cohorts, respectively. Either of adjuvant endocrine therapy or chemotherapy was given much more in the TisN1 and T1N1 cohorts than in the TisN0 cohort (80.0% and 88.9% vs. 5.4%). Other tumor characteristics were similar among the three cohorts. Although one patients had distant recurrence in the TisN0 cohort, none had locoregional or distant recurrences in the TisN1 and T1N1 cohorts. Regarding the lymph node status in the TisN1 and T1N1 cohorts, median tumor burdens in the SN are 590 and 310 copies/µL, and 2 (20.0%) and 2 (22.2%) patients had additional non-SN metastasis in the axillary dissection materials, respectively.

Conclusions: Tumor characteristics and prognosis were similar among the three cohorts albeit the TisN1 and T1N1 cohorts tended to received adjuvant systemic therapy. Moreover, the SN and non-SN status were similar between the TisN1 and T1N1 cohorts. Therefore, pathogenesis of nodal metastasis in DCIS cannot uniformly be explained, and tumors with different stages may be mixed in the node-positive DCIS. Thus, considering the favorable prognosis of node-positive DCIS, the clinical management should be determined on a case-by-case basis.
Effectiveness of Oncotype DX DCIS scoring in a community setting

James A Wheeler¹, Houman Vaghefi¹, Fang Liu², Victoria Owens¹, Laura Morris¹, Fiona Denham¹ and Leon Coody¹. ¹Goshen Center for Cancer Care, Goshen, IN and ²University of Notre Dame, Notre Dame, IN.

The Oncotype DX DCIS Score was developed to assist in determining a low risk for recurrence subgroup of patients who can avoid radiation therapy following breast conserving surgery. We sought to evaluate our experience using the Oncotype DX DCIS Score and to see if a greater number of patients who did not receive radiation therapy were experiencing a local recurrence than the score predicted.

Between February 23, 2011 and November 29, 2017, 145 women were diagnosed with ductal carcinoma in situ (DCIS) without an invasive component. 126 (87%) underwent breast conserving surgery. Thirty-five underwent Oncotype DX DCIS Score, of whom 26 (74%) were low risk, four were intermediate risk (11%), and five were high risk (14%).

The scores ranged from 0 (7 patients) to 100 (1 patient). Of the 26 patients with low risk scores, one chose to undergo mastectomy, three received radiation therapy, 20 chose observation without radiation therapy, and two patients were unknown because they had no further treatment or follow-up at our facility. Two of the four intermediate risk patients underwent radiation therapy and two did not. Four of the five high risk patients underwent radiation therapy, but one did not.

Twenty-two of the 35 patients who underwent Oncotype DX Score met the criteria for size (based on grade) and margins (at least 3 mm). Ten patients had margins that were less than 3 mm but met the size criteria. Two patients did not meet the size criteria but had at least 3 mm margins. One patient did not meet either the size or margin criteria. None of our 20 patients with low risk Oncotype DX DCIS Score and who met both the size and margin criteria recurred.

With the median follow-up of approximately 2-1/2 years, three of the 21 patients (14%) with low or intermediate risk scores who underwent Oncotype DX DCIS Score and did not receive radiation therapy suffered a local recurrence. The predicted average recurrence risk for these patients based on their Oncotype DX DCIS Score was 12%. Two of these patients who recurred had margins less than 3 mm, and one patient met the size and margin criteria, but had an intermediate risk score.

By comparison, five of 61 (8%) of patients who underwent breast conserving surgery and adjuvant radiation therapy had a local recurrence.

Twenty of the 23 (87%) low risk Oncotype DX DCIS Score patients did not receive radiation therapy and overall 20/35 (57%) of the patients undergoing Oncotype DX DCIS Score did not receive radiation therapy.

Although the follow-up is still relatively short, Oncotype DX DCIS Score allows a considerable number of women to avoid adjuvant radiation therapy.
Immunohistochemical staining and in vitro analysis of HER2-positive breast cancer using trastuzumab and pertuzumab to develop an appropriate tracer in image-guided surgery

Ryota Otsubo¹², Peter JK Kuppen², Shadhvi Bhairosingh², Alexander L Vahrmeijer², Vincent THBM Smit², Takeshi Nagayasu¹, Cornelis JH van de Velde² and Cornelis FM Sier². ¹Nagasaki University Hospital, Nagasaki, Japan and ²Leiden University Medical Center, Leiden, Netherlands.

Background: Pre- and intraoperative visualization of cancer cells using monoclonal antibody-based multimodal tracers can demarcate tumor margins in breast-conserving surgery. We focused on trastuzumab (Tmab) to develop a tracer for HER2-positive breast cancer by conjugation with a fluorescent dye. However, whether Tmab can be used as an imaging tracer for patients who receive Tmab as neoadjuvant therapy (NAD) is unclear, because tumor-cell HER2 could be bound by NAD Tmab at the time of surgery. This study evaluated immunohistochemical (IHC) staining and in vitro experiments with Tmab and pertuzumab (Pmab) as primary antibodies to find a suitable tracer. Pmab has a different antigen epitope than Tmab.

Methods: We included 43 patients with HER2-positive breast cancer, who were treated between 2010 and 2016. The NAD cohort (n=10, with 26 lesions) received chemotherapy and Tmab before surgery. The Tmab-naïve cohort (n=33, with 95 lesions) did not receive chemotherapy or Tmab before surgery. We excluded NAD patients with pathological complete responses. We evaluated the lesions, using IHC with Tmab and Pmab. We also performed flow cytometry and fluorescent microscopic analysis (FMA) using Tmab and Pmab conjugated with a fluorescent agent for the HER2-negative MCF7 and HER2-positive HCC1954 cell lines, which were pre-treated with Tmab to model NAD conditions.

Results: IHC with anti-HER2 antibody showed positive staining in all patients. Tmab staining was less intense, but positive Tmab IHC reactions were detected on tumor cell membranes in 77.8% of lesions in the naïve cohort and 70.8% in the NAD cohort. Pmab staining was seen in 46.3% of naïve cohort lesions and 22.2% of NAD lesions. Notably, we observed cytoplasmic staining in 87.8% of Pmab-negative cases in the NAD cohort. Flow cytometry showed less Tmab binding than Pmab binding in HCC1954 cells. After 24 hours' pretreatment incubation with Tmab, FMA showed a clear decrease in Tmab binding from 73.3% (without pretreatment) to 5.7%(after pretreatment), and a smaller decrease in Pmab binding from 72.7% (without pretreatment) to 66.4% (after pretreatment) in HCC1954 cells.

Conclusions: Pmab might be a suitable tracer for image-guided surgery after NAD, but identifying a suitable tracer for HER2-positive breast cancer will require further study.
Machine learning-based structural analysis and oxygen saturation measurement of tumor-associated vessels in breast cancer using a photoacoustic tomography system

Yoshiaki Matsumoto¹, Lin Gu², Ryoma Bise³, Yasufumi Asao⁴, Hiroyuki Sekiguchi¹, Aya Yoshikawa¹, Tomoko Ishii¹, Masahiro Takada¹, Masako Kataoka¹, Takaki Sakurai¹, Takayuki Yagi⁵, Imari Sato⁶, Kaori Togashi⁷, Tsuyoshi Shiina¹ and Masakazu Toi¹. ¹Kyoto University, Kyoto, Japan; ²National Institute of Informatics, Tokyo, Japan; ³Kyushu University, Fukuoka, Japan and ⁴Japan Science and Technology Agency, Tokyo, Japan.

Introduction
Breast cancer induces angiogenesis, one of the primary factors responsible for tumor progression. Therefore, the ability to visualize angiogenesis at a higher resolution is crucial. Photoacoustic tomography is a noninvasive method of visualizing angiogenesis involving light absorption and ultrasonic wave emission. If the irradiation light wavelength is adjusted for hemoglobin, vascular imaging is possible. Furthermore, using two wavelengths for oxidized and reduced hemoglobin, “S-factor,” can be calculated, which nearly corresponds to oxygen saturation. Therefore, photoacoustic imaging allows the assessment of breast lesions from vascular structural and functional viewpoints.

Objectives
This study aimed to demonstrate the possible utility of photoacoustic tomography for clinical application focusing on the morphologic features and oxygen saturation status of breast tumor-related vessels.

Methods
For the morphological analysis, we applied a machine learning-based method for automatic vessel extraction, and for the functional analysis we evaluated hemoglobin oxygen saturation calculating signals obtained at two wavelengths. In our system, a 3D ultrasound image was simultaneously acquired as a volume image of a tumor, which helped analyze the positional relationship between the vessels and the tumor.

Results
On morphological analysis, the fine structure of tumor-related vessels was rendered in high resolution. In our system, the blood vessels branched toward the tumor 2-3 more times more frequently than observed on contrast-enhanced MRI, illustrating a finer level of blood vessels near the tumor on our system than on MRI. Next, we analyzed the six morphologic features of vessels (radius, volume, curvature, contraction, maximum angle and vessel branch number) that are associated with the pathologic condition in neuroscience. We determined that the feature distribution of vessels located close to the tumor differed from that located away from the tumor. For example, vessels near the tumor had higher curvature, which means they are more tortuous than healthy vessels. The difference in the distribution of all six features was statistically significant on the Kolmogorov-Smirnov test.

On functional analysis, S-factor measurement of the healthy human breast demonstrated clearly demarcated arteries and veins. The S-factor of any artery was nearly 100%, while that of the veins inside the breast cancer tended to be a little higher (approximately 5%) compared to that in the healthy part. This tendency of veins was not recognized in benign tumors. This could show arteriovenous shunt in cancer microenvironment. We found low saturation signals emerging in the tumor tissue following bevacizumab-containing chemotherapy, indicating the possibility that our system reveals microenvironment changes.

Discussion
If our system can identify the structure or oxygen saturation characteristics unique to tumor-associated vasculature, it could contribute to the improved accuracy of breast cancer diagnosis and allow the observation of tumor vessel normalization because of the drug treatment. An earlier grasp of the therapeutic effect could lead to the provision of individualized medicine.
Exploring the relationship between an *in vitro* model of breast cancer cell mineralisation and the cancer grade specific composition of ex vivo microcalcifications

Pascaline Bouzy\(^1\), Shane O'Grady\(^2\), Francesca Palombo\(^1\), Maria P Morgan\(^2\) and Nicholas Stone\(^1\). \(^1\)Biomedical Physics Group, Physics and Astronomy, University of Exeter, Exeter, Devon, United Kingdom and \(^2\)Royal College of Surgeons in Ireland, Dublin, Ireland.

**Background:** Microcalcifications resulting from calcium deposition in the mammary gland play a central role in the early detection of breast cancer [1]. However, the relationship between their occurrence in the breast and cancer progression remains poorly understood. Our approach is to use vibrational spectroscopy and imaging, which is non-invasive, non-destructive, label-free and chemically specific, to assess the composition and distribution of the deposits in an *in vitro* cancer cell model of mineralisation [2]. In parallel we will utilise the same methods to measure the biochemical composition of microcalcifications found in breast biopsies from different grades of cancer. The ultimate aim of the study is to link the changes identified during the *in vitro* mineralisation process with the different stages of breast cancer. Vibrational spectroscopic methods can provide incredibly detailed biomolecular fingerprints enabling us to elucidate both the compositional changes with advancing pathology and the spatial distribution of those changes within the calcification and the surrounding tissue.

**Methods:** The breast cancer cell line MDA-MB-231 has the ability to produce mineralisation. This mineralisation was assessed over a 14-day period in the presence of different osteogenic cocktails: one composed of ascorbic acid, β-glycerophosphate (βG) and dexamethasone (Dex), and another one composed of inorganic phosphate (Pi). Fixed cells were analysed using Raman spectroscopy and micro-FTIR imaging at different time points (3, 7, 11 and 14 days). Tissue sections from patients with microcalcifications identified in histopathology will be sectioned to 3 mm and imaged with infrared (Agilent 670 FTIRinterferometer and Focal Plane Array imaging microscope) and Raman (Renishaw inVia) microspectrometers.

**Results:** We observed distinct and specific phosphate peak (PO\(_{4}^{3-}\)) at 960 and 1020 cm\(^{-1}\) in Raman and FTIR spectra, respectively, corresponding to hydroxyapatite crystal and indicating the presence of microcalcification formation. Treatment with Pi induced a faster mineralisation (day 3) compared to cells treated with βG (day 11) and different spectral profiles during this development phase. In addition, there are changes in both the relative DNA and protein concentrations in the cells following 11 days exposure to the osteogenic agents.

It has been shown that the level of carbonate substitution in the calcium hydroxyapatite crystal correlates directly with the pathology of the tissue surrounding the microcalcification. Here we compare the mineral composition found ex vivo versus the *in vitro* model.

**Conclusion:** It could be possible to link the progressive biophysical changes associated with mineralisation to distinct stages of breast cancer pathology based on protein, lipid and carbonated apatite contents of the mineralised cells.

**Support:** This work was conducted as part of the Marie Curie Innovative Training Network Mid-TECH [H2020-MSCA-ITN-2014-642661]

Initial experience of dedicated breast PET imaging of ER+ breast cancers using [F-18]fluoroestradiol

Ella F Jones¹, Kimberly M Ray¹, Rita Mukhtar¹, Wen Li¹, Benjamin L Franc¹, Laura J Esserman¹, Bonnie N Joe¹, Miguel H Pampaloni¹ and Nola M Hylton¹. ¹University of California, San Francisco, San Francisco, CA.

Introduction: Breast cancer is a heterogeneous disease encompassing distinct subtypes with variable treatment response, relapse risk and overall prognosis. The majority of breast cancers are estrogen receptor-positive (ER+). While neoadjuvant endocrine therapy trials have been proposed to better identify therapeutic approaches for ER+ breast cancer, accurate quantification of the ER biomarker is necessary to assess the primary tumor and its likelihood of response to treatment. Dedicated breast positron emission tomography (dbPET) is an emerging technology with a high spatial resolution that enables detection of sub-centimeter lesions and depiction of intratumoral heterogeneity. In this study, we report our initial experience with [F-18]fluoroestradiol (FES) dbPET in assessing ER+ primary breast cancers.

Materials and Methods: In an IRB-approved protocol, patients with biopsy-confirmed ER+ breast cancers were imaged with dbPET (MAMMI, OncoVision, Valencia, Spain) as a companion diagnostic tool to standard breast MRI. A dose of 5 mCi of FES was administered and patients were imaged in the prone position at 45 min post-injection. As part of routine clinical care, MR images were reviewed by a certified breast radiologist experienced in breast MRI. DbPET was reviewed by a radiologist specialized in nuclear imaging.

Results: Five patients with ER+ breast cancers were imaged. Patient ages ranged from 33 to 64. Two patients with infiltrating lobular carcinomas measuring up to 6.7 cm and 5.3 cm at MRI demonstrated corresponding FES tumor-to-normal maximum standard uptake value (SUV_{max}) ratio at 4.81 and 2.49 respectively. A third patient demonstrated multifocal FES uptake corresponding to multifocal invasive ductal carcinoma and ductal carcinoma in situ with disease foci ranging from 9-13 mm. In this patient, the more posterior disease foci seen on MRI were excluded from the field of view of dbPET. One patient demonstrated an absence of FES uptake in her 3.4 cm infiltrating ductal carcinoma, which was due to estrogen receptor blockade from the recent administration of tamoxifen for a fertility preservation procedure. The final patient had metastatic cervical and axillary lymphadenopathy secondary to a breast primary that was occult on mammography and MRI. FES-dbPET also showed no corresponding uptake in the ipsilateral breast, possibly due to the small size of the primary lesion and/or low tumor to background uptake ratio.

Conclusions: FES-dbPET imaging has potential as a diagnostic tool that is complementary to MRI in characterizing ER+ primary breast cancers. Limitations include variations of FES uptake in different ER+ breast cancer diseases and exclusion of posterior breast tissue near the chest wall and the axillary regions. However, FES-dbPET has a high potential for clinical utility, especially in measuring response to neoadjuvant endocrine treatment. Further development to improve the dbPET field of view and studies with a larger cohort of ER+ breast cancer patients are therefore warranted.
Detection of HER2 positive tumor cells using functionalized iron oxide nanoparticles

Farideh Z Bischoff	extsuperscript{1}, Kelsey Mathieu	extsuperscript{2}, Jose Vargas	extsuperscript{1}, Lan Pang	extsuperscript{2}, Adam M Kulp	extsuperscript{2}, Antimone Dewing	extsuperscript{1}, Xiangyou Liu	extsuperscript{1}, Robert C Bast	extsuperscript{2}, John Hazle	extsuperscript{2} and Marie Zhang	extsuperscript{1}. \textsuperscript{1}Imagion Biosystems, San Diego, CA and \textsuperscript{2}MD Anderson Cancer Center, Houston, TX.

**Background:** Iron oxide nanoparticles (NPs) have been used for a variety of in-vivo and ex-vivo applications within the biomedical sciences. Moreover, when intended for clinical in-vivo applications, NPs need to meet rigorous requirements to ensure safety as well as bio-functionality including blood circulation time and specificity for cellular targets. PrecisionMRX® NPs are extensively characterized superparamagnetic NPs composed of a 25nm magnetite cores that are currently employed in a variety of in-vivo applications including non-invasive/in vivo diagnosis of cancer, Magnetic Particle Imaging, MRI, and magnetic hyperthermia.

**Objective:** Here we report on the extensive pre-clinical development and functionality of antibody (Herceptin)-conjugated NPs for in-vivo and ex-vivo detection of HER2+ tumor cells by Magnetic Relaxometry (MRX).

**Results:** We observed: 1) specific binding and detection of HER2 positive tumor cells in-vitro; 2) specific detection of HER2+ tumors in mice; 3) binding and amplitude of magnetic signal to be proportional to the level of HER2 expression in-vitro and in-vivo; 4) the nanoconstruct remains stable in circulation; 5) the particles do not induce a pro-inflammatory response nor activate complement; 6) the particles are biodegradable; and do not induce acute or delayed signs of morbidity in mice.

**Conclusion:** Precision MRX® nanoparticles offer great clinical promise including the in- vivo detection of tumor cells by magnetic relaxometry. Given the stability and safety of these NPs, our pre-clinical results support progressing to clinical testing. A first-in human ex-vivo clinical research study design and strategy will be discussed.
Predictive models for CEUS of the breast: Is it feasible in improved performance of BI-RADS evaluation of critical breast lesions?——Primary analysis from multi-center prospective study in China

Jun Luo¹, Qin Chen¹, Lina Tang², Lichun Yang³, Ehui Han⁴, Yingrong Chen⁵ and Lijun Yuan⁶. ¹Sichuan Provincial People's Hospital, Chengdu, Sichuan, China; ²Fujian Provincial Cancer Hospital, Fuzhou, Fujian, China; ³Yunnan Tumor Hospital Third Affiliated Hospital of Kunming Medical University, Kunming, Yunnan, China; ⁴Huangshi Central Hospital, Huangshi, Hubei, China; ⁵Chengdu First People's Hospital, Chengdu, Sichuan, China and ⁶Tangdu Hospital, Xian, Shanxi, China.

[Background]
Breast imaging reporting and data system (BI-RADS) is wildly used to assess malignant risk of breast lesions but causes high false-positive biopsy.

[Objective]
To determine whether predictive model for contrast-enhanced ultrasound (CEUS) of the breast can improve the precision of BI-RADS.

[Methods]
A total of 1034 patients with 1060 solid breast lesions (5.0-39.8mm, 17.89± 8.65mm) classified as BI-RADS 4 or 5 on conventional ultrasound and mammography were evaluated. CEUS was performed before core needle biopsy or surgical resection and a revised BI-RADS classification was assigned based on 6 predictive models for CEUS of malignant and benign breast lesions as follows: malignant predictive models: (1) hyper-enhancement with enlarged size, with or without irregular shape; (2) hyper-centripetal enhancement with perfusion defect, with or without enlarged size; (3) rapid or synchronous wash-in with hyper- or iso-enhancement, present penetrating vessels or crab claw-like pattern, with or without perfusion defect. Benign predictive models: (4) rapid wash-in with hyper-enhancement, clear margin after enhancement without enlarged size; (5) synchronous or slow wash-in with iso-enhancement, and cannot distinguish margin and shape after enhancement; and (6) synchronous or slow wash-in with hypo-enhancement, with equal or smaller size after enhancement. Receiver operating characteristic curve analysis was then conducted to evaluate the diagnostic performance of CEUS-based BI-RADS assignment with pathological examination as reference criteria.

[Results]
The CEUS-based BI-RADS evaluation classified 287/1060 (27.08%) lesions into category 3, 195 (18.40%), 124 (11.7%) and 144 (13.58%) lesions into categories 4A, 4B and 4C, respectively, and 310 (29.24%) into category 5, compared with 423/1060(39.91%), 348(32.83%), 150(14.15%) and 139(13.11%) in BI-RADS 4A, 4B, 4C, and 5 based on conventional ultrasound and mammography. Selecting CEUS- based BI-RADS category 3 as an appropriate cut-off gave accuracy, sensitivity, specificity, positive and negative predictive values of 69.25%, 98.06%, 49.47%, 58.99% and 96.86%, respectively for the diagnosis of malignant disease. The cancer-to-biopsy yield was 60.16% with CEUS-based BI-RADS 3 selected as the biopsy threshold compared with 43.86% otherwise, while the biopsy rate was only 72.92% compared with 100% otherwise(Figure 2). Overall, only 1.94% of invasive cancers were misdiagnosed as BI-RADS 3 we use nowadays.

[Conclusion]
This study suggests that evaluation of BI-RADS 4 or 5 breast lesions with CEUS result in reduced biopsy rates and increased cancer-to-biopsy yields.
Near-infrared spectral tomography (NIRST): A prognostic assessment tool for predicting residual cancer burden (RCB) during neoadjuvant chemotherapy (NAC) in breast cancer (BC)

Bhavina Batubhai1, Shudong Jiang2, Erica B Bernhardt1, Kristen Muller1, Xu Cao², Jiang Gui3, Roberta M DiFlorio-Alexander1, Mary D Chamberlin1, Gary N Schwartz1, Keith D Paulsen2, Brian W Pogue2 and Peter A Kaufman1.1 Dartmouth Hitchcock Medical Center, Lebanon, NH; 2 Dartmouth College, Hanover, NH and 3 Dartmouth Geisel School of Medicine, Hanover, NH.

Background: NIRST, a noninvasive imaging with no ionizing radiation, has been found to be prognostic as a tool to monitor early pathologic response to NAC in BC using biophysical properties of the tumor compared with normal breast tissue. We aim to establish NIRST indicators as early surrogates of treatment response and to evaluate its potential as a predictive tool in treatment decisions.

Methods: 27 women with locally advanced BC undergoing NAC were enrolled in this pilot study. NIRST imaging was performed pre-treatment, after cycle 1 and 2, at the mid-point of NAC, and at the conclusion of NAC prior to surgery. Biophysical data including oxy- and deoxy-hemoglobin, water, lipid, and scatter components were obtained at these time points. To minimize inter-subject variability due to breast density and its effects on the NIRST data, statistical analysis was conducted using ratios of obtained biophysical data to pretreatment average of the contralateral normal breast tissue. Residual Cancer Burden (RCB) index was used to evaluate residual disease after treatment with NAC. RCB scores and classes were determined in 24 of the 27 surgical tissue specimens and these were compared to the NIRST data. RCB data for 3 patients were excluded: 2 patients had undergone positive excisional lymph node biopsy prior to NAC and 1 patient had surgery at an outside hospital.

Results: Of the 27 patients, 7 had triple negative BC and 13 had HER-2 positive BC. The change in total hemoglobin (ΔHb-T %) after the first cycle of NAC when compared to the pre-treatment total hemoglobin was determined to be the best predicting factor for RCB (p-value <0.001). The Pearson correlation coefficient was calculated for both RBC class and RBC score (0.7 and 0.6). The significance of the correlation coefficient was evaluated using two-sided t-test and the resulting P-values of 0.006 and 0.001 respectively demonstrate that these correlations are statistically significant.

Summary of the NIRST biophysical data and the correlating RCB

**Conclusions:** We have demonstrated a statistically significant correlation between $\Delta$Hb-T % after the first cycle of NAC and the RCB. These findings suggest the potential of using NIRST as an early assessment tool to evaluate response to NAC in BC patients and warrant further evaluation in a larger study.
Interpretation schema for optical coherence tomography images in breast tissue

Kiran S Yemul¹, Adam M Zysk¹, Andrea L Richardson², Krishnarao V Tangella³ and Lisa K Jacobs⁴. ¹Diagnostic Photonics, Inc., Chicago, IL; ²Sibley Memorial Hospital, Washington, DC; ³Christie Clinic, Pathology, Urbana-Champaign, IL and ⁴Johns Hopkins Hospital, Surgery, Baltimore, MD.

Purpose
Optical coherence tomography (OCT) is an attractive technology for surgical imaging because it permits the real-time visualization of microscopic tissue morphology with a handheld probe without the need for exogeneous agents, tissue manipulation, ionizing radiation, or histological processing. While initial studies have shown that OCT is an effective margin-evaluation tool for breast conserving surgery (BCS), image interpretation and feature identification have not been directly studied. In this work, breast pathologies were assessed with a handheld OCT probe and the images were compared to histology.

Methods
Mastectomy and BCS specimens from 26 women were imaged with a handheld OCT probe, and histology slides from the same region were digitally photographed. OCT and histology images from the same region were paired by selecting the best structural matches. Because image characteristics in OCT are akin to those in ultrasound, descriptive OCT image feature terminology similar to that of ultrasound was developed. Each of these characteristics was used to select and describe OCT-histology image matches.

Results
In total, 2880 OCT images were acquired from 26 breast specimens, and 48 matching OCT-histology image pairs were identified. These matched image pairs illustrate tissue types including adipose tissue, dense fibrosis, fibroadipose tissue, blood vessels, regular and hyperplastic ducts and lobules, cysts, fibroadenoma, IDC, ILC, DCIS, calcifications, and biopsy cavities. Differentiation between pathologies was achieved by considering feature boundaries, interior appearance, posterior shadowing or enhancement, and overall morphologic patterns.

Conclusions
This is the first work to systematically catalog the features of breast OCT images. The results indicate that OCT can be used to identify important structures and distinguish between benign and malignant breast pathologies.
Ultrasound assessment of residual disease after neoadjuvant chemotherapy (NACT) in node positive triple negative breast cancer (TNBC)

Beatriz E Adrada¹, Vicente Valero¹, Sangeetha M Reddy¹, Carlos H Barcenas¹, Rosalind Candelaria¹, Wei Wei¹ and Gaiane M Rauch¹. ¹MD Anderson Cancer Center, Houston, TX.

Purpose: To determine accuracy of preoperative ultrasound after NACT to predict residual disease in triple negative breast cancer (TNBC) patients with confirmed axillary nodal metastasis.

Methods: This is an institutional review board approved retrospective study of TNBC patients who received NACT at MD Anderson Cancer Center from January 1999 - June 2015. We identified 327 TNBC patients who had cytologically confirmed breast and nodal disease at baseline evaluation and had preoperative ultrasound evaluation of residual disease. Ultrasound response was divided in three categories: radiologic complete response (rCR) - complete resolution of the malignant mass); near-rCR - no discernible mass, only an isoechoic flat tumoral bed); and residual disease (RD) - a discernible mass is seen. Axillary ultrasound images were evaluated for lymph node size, cortical thickness and residual morphological type after NAC (type I-VI). Ultrasound breast and axillary findings were compared with final surgical pathology.

Results: In 89 cases (27%), pCR was achieved. 74% (242/327) were unifocal and 26% (86/327) multifocal. Ultrasound rCR was seen in 11% patients (36/327). Of those, 64% (23/36) showed pCR and 36% (13/36) showed residual disease. Ultrasound near-rCR was seen in 26% (84/327). Of those, pCR was seen 49% (41/84) and residual disease in 51% (43/84). Residual disease was seen in 63% (207/327), 12% (25/207) showed pCR and 88% (182/207) showed residual disease. Regarding axillary lymph nodes, long axis diameter mean was 1.57 cm for patients with pCR and 1.6 cm for no pCR, short axis diameter mean was 0.67 cm for pCR and 0.87 cm for no pCR. Cortical thickness mean was 2 mm for pCR versus 9 mm for no pCR.

Sensitivity of ultrasound for assessment residual disease (ultrasound was considered positive if either breast ultrasound or axillary ultrasound showed residual disease) was 97%. Specificity is 22.47% with a NPV of 74% and PPV of 77%.

Conclusion: Breast and axillary ultrasound performed after NACT showed low specificity but high sensitive to detect residual disease. rCR and near rCR were related with pCR in 64% and 49% of the cases respectively.
Downstream workup after post-treatment mammography in breast conservation therapy: Is there a significant difference between tomosynthesis and 2-dimensional mammograms?

Brittany L Colosimo¹, Kevin Weinberger¹, Shaakir Hasan², Steven Gresswell², Sidney Anderson², Rodney E Wegner² and Mark Trombetta². ¹Lake Erie College of Osteopathic Medicine, Erie, PA and ²Allegheny Health Network Cancer Institute, Pittsburgh, PA.

Introduction:
Emerging data suggest that tomosynthesis mammograms (TS) are considerably superior to two-dimensional (2D) screening mammograms (2DMG) at reducing false positive biopsies for breast cancer screening. However, very little is reported about the comparative efficacy of the two modalities in the post-treatment setting. We compared the rate of downstream workup up after undergoing post-radiation screening 2DMG and TS following breast conservation therapy at our institution.

Methods:
Between the years 2011-2017, 712 breast cancer patients (range 31-91 years) were treated with lumpectomy and adjuvant radiotherapy. As per institutional standard, follow up included either screening 2DMG (n=569) or TS(n=143) and reviewed in this IRB-approved study. The primary endpoint for comparison was the rate of further imaging/workup post-treatment . Comparative analysis was conducted via multivariable binomial regression with propensity matching between the 2DMG and TS groups. Patients with clinical suspicion of recurrence otherwise were excluded.

Results:
The patient cohort in both groups included the following clinical characteristics,: 129 patients with ductal carcinoma in-situ (the remainder were invasive carcinoma; ductal or lobular). A total of 418 patients had T1 lesions, 143 T2, and 22 T3/T4. Eighty-five patients were node positive. Of those, 501 ER+/Her2-, 101 triple negative, and 96 triple positive. Adjuvant radiation included conventional fraction (457) or hypofractionation (153) with boost to the surgical cavity in523Accelerated Partial Breast Irradiation (APBI) was delivered in 106 patients. Post treatment scans occurred within 3 months (166), at 3-6 months (256), or 6+ months (281). The aforementioned characteristics were similarly distributed between 2DMG and TS groups, except for slightly more DCIS in the 2D group.

There was a significantly higher proportion of patients that were recommended for immediate downstream workup in the 2D group (40.7%) compared to in the tomo group (16.8%) (HR = 3.40, P <0.001), leading to 12 biopsies in the 2D group (3 positive) and 4 biopsies in the TS group (0 positive). Upon multivariate analysis, the use of tomo was the lone correlate of reduced downstream workup (p < 0.05), although there was a trend toward significance in patients who were first imaged at a post-treatment interval of 6+ months and in patients not undergoing a radiation boost (P < 0.10).

Conclusion:
Post-breast conservation follow-up with tomo synthesis mammography resulted in significantly less downstream workup as compared to conventional 2D screening mammography. Further investigation is warranted to unveil the absolute and relative cost-effectiveness between the two modalities.
Characteristics of lymphocyte-predominant breast cancer in ultrasound images and their application to diagnostic prediction

Kayo Fukui¹, Norio Masumoto², Noriyuki Shiroma¹, Akiko Kanou¹, Michiya Yokozaki¹, Shinsuke Sasada², Akiko Emi², Takayuki Kadoya², Koji Arihiro¹ and Morihito Okada². ¹Hiroshima University Hospital, Hiroshima, Japan and ²Hiroshima University, Hiroshima, Japan.

**Purpose**
Tumor-infiltrating lymphocytes (TILs) is a prognostic factor for breast cancer, however, an accurate and simple evaluation method remains elusive. Therefore, we focused on findings characteristic of lymphocyte-predominant breast cancer (LPBC) in ultrasound (US) images. In this study, the application of preoperative US image assessment to diagnostic prediction of LPBC evaluated from postoperative pathological specimens, was appraised.

**Methods**
We evaluated 191 patients with invasive breast cancer between January 2014 and December 2017. All patients were treated by either mastectomy or breast-conserving surgery. Stromal lymphocytes were evaluated on surgical pathological specimens. Breast cancer samples with ≥ 50% stromal TILs were defined as LPBC. Preoperative US was performed in all cases and images were examined for characteristics indicative of TILs. Scores were given to US images with characteristic TILs and these TILs-US scores were assessed for their application to predict LPBC.

**Results**
There were 39 cases of LPBCs and 122 cases of non-LPBCs in surgical pathological specimens. The characteristic US image findings predicting LPBC were shape (more lobulated), internal echo level (weaker) and posterior echoes (stronger). The TILs-US scores were given based on these three ultrasound tissue characterizations. We set TILs-US score cut-offs for predicting LPBC at 4 points (Sensitivity, 0.73; specificity, 0.87; accuracy, 0.83) based on the receiver operating characteristics (ROC) curves (AUC, 0.88). There were significant predictors for LPBC in multivariate logistic analysis (Nuclear Grade (NG): OR3.4, p=0.02; ER: 5.7, p =0.007;HER-2: OR4.1, p=0.04; TILs-US score2: OR14.9, p<0.001) in preoperative clinicopathological factor. The sensitivity, specificity and accuracy of NG for predicting LPBC were 0.75, 0.69 and 0.71. Those of ER and HER2 were 0.33, 0.96 and 0.79. Sensitivity, specificity, and accuracy of NG, ER, and HER2 diagnoses were all lower than the TILs-US score, and the TILs-US score showed the best diagnostic ability.

The sensitivity, specificity and accuracy of predicting LPBC

**Conclusions**
LPBC has characteristic ultrasound tissue characterizations in US images. Thus, TILs-US scores based on US may be applicable to accurate and convenient preoperative diagnosis of LPBC.
Is real-time rescanning by radiologists necessary for all ACR BI-RADS US category 3 to 5 lesions in the diagnostic setting?

Yue Hu¹, Jingsi Mei¹, Xiaofang Jiang¹, Qiang Liu¹ and Chang Gong¹. ¹Breast Tumor Center, Sun Yat-Sen Memorial Hospital, Guangzhou, China.

**Purpose:** To assess the value of radiologists’ rescanning before final interpretation for American College of Radiology (ACR) Breast Imaging Reporting and Data System ultrasonography (US) category 3–5 lesions.

**Materials and Methods:** Image data on 1070 patients with 1070 category 3–5 breast lesions with a pathological diagnosis scanned between January 2016–June 2017 were included. Both real-time and static images were acquired for each lesion. The diagnostic performance of assessing static images and rescanning by the radiologist were each calculated. The positive predictive values (PPVs) of each category in the two groups were calculated and compared.

**Results:** The sensitivity, specificity, PPV, and negative predictive value for real-time US were 98.9%, 58.2%, 44.8% and 99.4%, and for static images were 98.9%, 57.1%, 44.1% and 99.3%, respectively. Areas under the curves were not significantly different if final assessment was only dichotomized as negative or positive (≥ category 3: \( P = .566 \)). Significant differences were observed if more detailed classification was performed (category 3–5 without subcategory: 0.969 vs. 0.955, \( P = .0113 \); category 3–5 with subcategory 4A–4C: 0.915 vs. 0.855, \( P < .0001 \)). All PPVs of each category for each assessment were within the reference range provided by the ACR in 2013 except subcategory 4B of static image evaluation, which was also significantly higher than that of real-time assessment (54.8% vs. 40.7%, \( P = .037 \)). BI-RADS US of real-time and static images evaluation correlate with pathology are listed in Table 1.

BI-RADS US Breast Imaging Reporting and Data System for Ultrasonography, PPV positive predictive value, ACR American College of Radiology

The overall agreement of the two approaches was moderate (\( \kappa = 0.43 \) if lesions were assigned to category/subcategory 3, 4A–4C, 5).

**Conclusion:** Both static image evaluation and real-time assessment had similar diagnostic performance for most lesions; however, the diagnostic performance of static image evaluation for subcategory 4B lesions was lower. Real-time rescanning by the interpreter is strongly recommended for lesions of subcategory 4B after assessing static images. YH and JM contributed equally to this study.
SUV max of 18F FDG-PET/CT: A predictive factor associated with pathologic complete response in luminal HER2-negative breast cancer patients (receiving neoadjuvant chemotherapy)

In Hee Lee¹, Soo Jung Lee¹, Jiyeon Lee¹, Ryu Kyung Lee¹, Jinho Yang Jung¹, Hoyong Park¹, Sang-woo Lee² and Yee Soo Chae¹.
¹Kyungpook National University Chilgok Hospital, Kyungpook National University School of Medicine, Daegu, Korea and
²Kyungpook National University Chilgok Hospital, Daegu, Korea.

Purpose Neoadjuvant chemotherapy (NAC) is considered to be the standard of care for locally advanced breast cancer. When pathological complete response (pCR) is obtained with NAC it is a predictor of better outcome and often used as a surrogate for survival. However, response to NAC of luminal type breast cancer is variable and mostly limited. This study investigated the predictive relevance of several clinicopathological factors, including parameters of 18F FDG-PET/CT, on the pCR to NAC in patients with luminal HER2-negative breast cancer.

Methods From 2009 to 2015, 117 hormone receptor-positive, HER2-negative breast cancer patients who were treated with NAC followed by curative surgery at the Kyungpook National University Hospital (Daegu, Korea) were retrospectively analyzed. pCR was defined as the absence of cancer cells in breast and axillary node. 18F FDG-PET/CT maximum standardized uptake value (SUV max) was measured at baseline. Patients received from 6 to 8 cycles of anthracycline-based and taxane-based NAC.

Results The median age of the patients was 48 years (range-29-68 years). 104 patients (88.9%) were PR-positive, and forty-nine (41.9%) patients showed high ki-67 expression at initial diagnosis. After NAC, nine patients (7.7%) achieved pCR and patients who had high initial SUV max (≥9.09) achieved improved pCR rate compared to low initial SUV max (<9.09) patients (77.8% vs. 22.2%).

Conclusion In luminal HER2-negative breast cancer, 18F FDG-PET/CT SUV max was useful for predicting pathologic complete response after NAC.

Diagnostic performance of dedicated breast PET for the prediction of pathological response after neoadjuvant chemotherapy

Eri Suzuki¹, Shinsuke Sasada¹, Satoshi Sueoka¹, Norio Masumoto¹, Noriko Goda¹, Keiko Kajitani¹, Akiko Emi¹, Rumi Haruta¹, Takayuki Kadoya¹, Tsuyoshi Kataoka¹ and Morihito Okada¹. ¹Hiroshima University, Hiroshima City, Japan.

Background: Neoadjuvant chemotherapy (NAC) is a standard treatment for operable breast cancer. However, imaging methods for evaluating treatment response have not been established. Previous studies reported that ring-type dedicated breast positron emission tomography (DbPET) detected residual tumors following NAC more accurately than whole-body PET/CT. This study assessed DbPET parameters for predicting pathological complete response (pCR) in patients with breast cancer.

Patients and Methods: Among patients with breast cancer who underwent surgery after NAC, 61 were examined using ring-type DbPET before and after NAC. The maximum standardized uptake values (SUVmax) and tumor-to-normal-tissue ratio (TNR) were calculated before and after NAC (pre-SUVmax, pre-TNR, post-SUVmax and post-TNR, respectively). Moreover, the reduction rates (ΔSUVmax and ΔTNR) were determined. pCR was defined as complete remission of breast cancer.

Results: The median patient age was 52 years. Forty patients (65.6%) were estrogen receptor (ER)-positive, whereas 25 patients (41.0%) were HER2-positive. Fifteen patients (24.6%) achieved pCR after NAC. The calculated values for the parameters of DbPET are summarized in Table 1. The most promising parameters for predicting pCR were ΔSUVmax (area under the curve [AUC]: 0.506) and post-TNR (AUC: 0.640)

pCR, pathological complete response; IQR, interquartile range; AUC, area under the curve; CI, confidence interval, SUV, standardized uptake value; TNR, tumor-to-normal-tissue ratio.

Although neither of these two parameters reflected the pathological response to NAC in patients with ER-positive disease, post-TNR showed the highest AUC (i.e., AUC: 0.750) for pCR in patients with ER-negative disease. The sensitivity and specificity of post-TNR in the ER-positive group were 85.7% and 39.4%, respectively. In the ER-negative group, these values were 100% and 58.3%, respectively

Conclusion: In DbPET, ΔSUVmax and post-TNR were shown to be promising parameters for predicting pathological response to NAC. Post-TNR provided the highest sensitivity for predicting pCR in patients with ER-negative breast cancer.
Early ultrasound evaluation for prediction of treatment response to neoadjuvant chemotherapy in triple negative breast cancer patients

Beatriz E Adrada¹, Rosalind Candelaria¹, Stacy Moulder¹, Deanna Lane¹, Lumarie Santiago¹, Elsa Arribas¹, Ken R Hess¹, Vicente Valero¹, Alastair Thompson¹, Thorunn Helgason¹, Elizabeth Ravenberg¹, Wei Yang¹ and Gaiane M Rauch¹. MD Anderson Cancer Center, Houston, TX.

Background: Triple negative breast cancer (TNBC) is molecularly heterogeneous disease. Genomic profiling to identify the distinct TNBC subtypes is costly with long turnaround time. Early ultrasound after two cycles of neoadjuvant chemotherapy (NAC) has the potential to identify patients who are likely to have pathological complete response. Suspected non-responder patients can undergo comprehensive genetic testing and triaged for specific targeted therapeutic trials.

Aim: To determine the value of ultrasound evaluation after two cycles of NAC to predict complete pathologic response in TNBC breast cancer patients.

Methods: 98 patients enrolled in “A randomized triple Negative Breast Cancer Enrolling Trial to Confirm Molecular Profiling Improves Survival” (Artemis) at the University of Texas MD Anderson Cancer Center had ultrasound evaluation before treatment and after two cycles of NAC (Adriamycin and Cyclophosphamide). Three-dimensional measurements of the tumor were obtained at baseline and after 2 cycles of the NAC. Change in the tumor volume after 2 cycles of NAC was calculated. Residual cancer Volume (RCB) was calculated based on the final histopathology at surgery. Linear regression analysis evaluated associations between residual cancer burden (RCB) and change in volume of the index tumor.

Results: Median tumor size at diagnosis was 3 cm, range 0.6-11.9cm. Median size after two cycles was 2 cm, range 0.6-12.8 cm. RCB 0-I was seen in 55% of patients (54/98). Linear regression analysis demonstrated that of 22 patients with volume reduction >75%, 18 patients (82%) had RCB0-I (95%CI, 61%-93%).

Conclusion: Our data suggest that ultrasound exam after 2 cycles of NAC can identify TNBC patients who are unlikely to respond to standard NAC. These non-responder TNBC patients can be triaged for additional genetic testing and subsequent targeted clinical trials. Study on the larger number of patients is currently on the way.
The TILs-US scores based on ultrasonography can predict lymphocyte-predominant breast cancer before surgery

Akiko Kanou¹, Norio Masumoto², Noriyuki Shiroma¹, Kayo Fukui¹, Shinsuke Sasada², Akiko Emi², Takayuki Kadoya², Michiya Yokozaki¹, Koji Arihiro¹ and Morihito Okada². ¹Hiroshima University Hospital, Hiroshima City, Hiroshima, Japan and ²Hiroshima University, Hiroshima City, Hiroshima, Japan.

Purpose
Tumor-infiltrating lymphocytes (TILs) has been shown to be useful for predicting outcomes after surgery in breast cancer, and while TILs can be evaluated in preoperative biopsy tissue, heterogeneous distribution of TILs requires examination of all biopsied tissue samples.

We gave scores to preoperative ultrasonography (US) images with characteristics indicative of lymphocyte-predominant breast cancer (LPBC) and attempted to apply these for diagnostic prediction of LPBC. In this study, TILs-US scores based on preoperative US were assessed for their usefulness in predicting LPBC, the diagnosis of which was confirmed with postoperative pathology.

Methods
We evaluated 161 patients with invasive breast cancer between January 2014 and December 2017. All patients were treated by either mastectomy or breast-conserving surgery. Stromal lymphocytes were evaluated on preoperative biopsy tissues and surgical pathological specimens. Breast cancer samples with ≥ 50% stromal TILs were defined as pre-LPBC (preoperative biopsy tissues) and LPBC (surgical pathological specimens). TILs-US score was calculated from US before curative surgery. Based on clinicopathological factors including TILs-US scores based on preoperative US and pre-LPBC indicators, determinants useful for prediction of LPBC were examined.

Results
There were 39 cases of LPBCs and 122 cases of non-LPBCs in surgical pathological specimens. We set TILs-US score cut-offs for predicting LPBC at 4 points based on the receiver operating characteristics (ROC) curves (AUC, 0.88). There were significant predictors for LPBC in multivariate logistic analysis (TILs-US score: OR26.8, p<0.001; pre-LPBC: 18.6, p=0.002; HER-2: OR9.2, p=0.009) in preoperative clinicopathological factor. The sensitivity, specificity and accuracy of TILs-US score for predicting LPBC were 0.74 (0.62-0.84), 0.89 (0.85-0.92) and 0.85 (0.79-0.90). Those of pre-LPBC were 0.51(0.42-0.55), 0.98 (0.96-1.00) and 0.87 (0.82-0.89), and those of HER2 were 0.28(0.19-0.36), 0.94(0.91-0.97) and 0.78 (0.74-0.82), respectively. The sensitivity of TILs-US score for predicting LPBC was significantly greater than those of pre-LPBC (p=0.04) and HER2 (p<0.001). On the other hand, the specificity of pre-LPBC for predicting LPBC was significantly greater than that of TILs-US score(p=0.002).

Conclusions
TILs-US scores are an important factor that can predict LPBC preoperatively. The TILs-US score has particularly high sensitivity and may be an applicable index in the preoperative evaluation for LPBC.
Artificial Intelligence over thermal images for radiation-free breast cancer screening

Geetha Manjunath1, S Sudhakar2, Sivateja Kakileti1, Himanshu Madhu1 and Akshita Singh3. 1NIRAMAI Health Analytix Pvt Ltd, Bangalore, India; 2HealthCare Global Enterprises Ltd, Bangalore, India and 3Narayana Hrudayalaya Limited, Bangalore, India.

Introduction: Breast cancer is the largest cause of cancer deaths in women today. NIRAMAI has developed a novel solution for detecting early stage breast cancer in women of all age groups. It is low cost, non-contact and portable solution. This radiation-free solution also works on dense breasts and hence is applicable beyond developing countries. The core of the solution is a Computer Aided Diagnostics engine called Thermalytix, which uses Artificial Intelligence algorithms on high resolution thermal images.

In this paper, we present a comparative analysis of Thermalytix solution with Mammography, the standard screening modality, in a retrospective trial that was conducted across 3 reputed cancer hospitals in India.

Aim: To compare the sensitivity, specificity, NPV and PPV of Thermalytix with Mammography.

Methods: A multisite comparative study was performed on 194 patients across 3 reputed cancer hospitals in India with informed consent from subjects and ethics committee approval of respective hospitals. Every person who was going for a mammography test was made to undergo the non-invasive Thermalytix test prior to mammography examination. As per standard of care in India, all women who had a suspicious lesion in Mammo was sent to Ultrasound and then biopsy. 93 of the 194 subjects enrolled were found to be malignant by this standard procedure (9 of them did not have a biopsy report).

Niramai Thermaytix test gave the automated reports detecting patients with suspected malignancy and those results were compared with ground truth derived from mammography, sono-mammography and biopsy. In a similar manner, standalone mammography observation was compared with the above ground truth to compare the two modalities as individual modalities.

Results:
Out of the 194 subjects, 93 positive cases and Niramai accurately detected 91 cases and called out one as boundary case. Sensitivity of Thermalytix was 98% and NPV was 97%, while sensitivity of Mammography was 94% with an NPV of 94%.
NIRAMAI Thermalytix detected 4 more malignant patients compared to Mammography. On the other hand, mammography scored over Thermalytix in PPV and Specificity by 10%. These results are tabulated at

Number of subjects = 194 high risk patients

Among the 194 patients, 39 women were found to have dense breasts and 19 with heterogenous dense breasts – on whom ultrasound and elastography was performed by the Radiologist to correlate with mammography results and make the final observations. Niramai test alone was effective in these patients.

The results show that Thermalytix is an emerging, radiation-free diagnostic modality that has comparable accuracy to Mammography. We conclude that NIRAMAI Thermalytix can be complementary modality to mammography as it works well on women of all age groups, including women with dense breasts. Its higher sensitivity and NPV adds to its potential to be the first screening test for early detection of breast cancer.
Analysis of non-cancerous lesion with high FDG uptake in breast

Wanying Xing¹, Qiang Li¹, Guang Sun¹, Rangjuan Cao¹, Bin Chen¹, Chengwei Jiang¹, Lei Ma¹ and Keren Wang¹. ¹China-Japan Union Hospital of Jilin University, Changchun, Jilin, China.

Background
Positron emission tomography (PET) is an imaging method that provides insight into the metabolism of glucose in tissues, and the most widely used tracer is 18F-fluorodeoxyglucose (18F-FDG). Fluorodeoxyglucose (FDG) is transported by glucose transporters, metabolized by the enzyme hexokinase and builds up in cancer cells. So FDG uptake within cells mainly depends on cellular metabolic activity and the number of glucose transporters. However, this mechanism is not specific to cancer cells. FDG can accumulate in inflammatory cells and benign processes, causing false-positive findings. In this study, we analyzed the non-cancerous lesion diagnosed by histology which showed abnormal absorption of FDG in 18F-FDG PET/CT test and demonstrated the image feature of these cases.

Materials and Methods
We undertook a retrospective review of data from 373 women who had an 18F-FDG PET/CT test and analyzed the false positive results in 48 cases according to final pathological results between January 2016 and April 2018.

Results
Of 296 patients, who had abnormal FDG absorption, 248 cases were histological diagnosed with breast carcinoma and 48 cases were non-cancerous disease including fibroadenoma, intraductal papilloma, adenomyoepithelioma, purulent inflammation, cyst with ductal ectasia, adenosis, tuberculosis and fibroadenoma with inflammation. We focused on the 48 cases with false positive FDG absorption, and the pathological results and 18F-FDG PET/CT of these patients were showed in Table 1. Fibroadenoma and purulent inflammation accounted for 33.3% and 35.4% of all cases following by intraductal papilloma with the incident of 12.5%. In purulent inflammation cases the max diameter of tumor showed significantly larger than other cases (3.2±1.2, P<0.05).The max diameter of lesion in other diseases showed no significantly differences. 18F-FDG PET/CT results showed that the value of SUVmax in purulent inflammation was significantly higher than that in other diseases (13.2±2.2, P<0.05), and adenomyoepithelioma, cyst with ductal ectasia and adenosis were showed with a lower SUVmax.

Conclusion
In conclusion, despite the low false positive rate, 18F-FDG PET/CT is of great value for preoperative evaluation of breast lesion. In the non-cancerous cases which had a indication of carcinoma in 18F-FDG PET/CT test, the most common diagnosis were fibroadenoma, purulent inflammation and intraductal papilloma. The characteristics of purulent inflammation in 18F-FDG PET/CT image presented a higher SUVmax value with a larger max diameter in length.
TILs-US score using ultrasonography before chemotherapy predicts the outcome of neoadjuvant treatment in HER2 positive breast cancer

Norio Masumoto¹, Takayuki Kadoya¹, Akiko Kanou², Kayo Fukui², Noriyuki Shiroma², Satoshi Sueoka¹, Eri Suzuki¹, Goda Noriko¹, Shinsuke Sasada¹, Akiko Emi¹, Rumi Haruta², Tsuyoshi Kataoka², Koji Arihiro² and Morihito Okada¹. ¹Hiroshima University, Hiroshima, Japan and ²Hiroshima University Hospital, Hiroshima, Japan.

Purpose
Tumor-infiltrating lymphocytes (TILs) have been reported to be predictive factors of therapeutic effect in neoadjuvant chemotherapy (NAC). And while TILs can be evaluated in preoperative biopsy tissue, heterogeneous distribution of TILs requires examination of all biopsied tissue samples. We gave scores to preoperative US images with characteristics indicative of LPBC and attempted to apply these for diagnostic prediction of LPBC. In this study, TILs-US score based on US images obtained before chemotherapy was examined as an alternative method to LPBC evaluated on preoperative biopsy tissues (pre-LPBC) for application in the prediction of pathological complete response (pCR).

Methods
We evaluated 67 patients in triple negative type (n=22), HER-2 positive (n=33), luminal type (n=12) with invasive breast cancer who underwent neoadjuvant chemotherapy between March 2012 and July 2016. Ultrasonography (US) was performed before NAC. All patients were treated by either mastectomy or breast-conserving surgery after NAC. Stromal lymphocytes were evaluated on preoperative biopsy tissues. Breast cancer samples with ≥ 50% stromal TILs were defined as LPBC. There were 39 cases of LPBCs and 122 cases of non-LPBCs in pathological specimens using a biopsy before NAC. TILs-US score (0~7 point) was calculated from US before NAC. We set TILs-US score cut-offs for predicting LPBC at 4 points based on our previous data. Based on clinicopathological factors including TILs-US scores based on US and LPBC indicators before NAC, determinants useful for prediction of LPBC were examined.

Results
The surgical pathological findings after NAC indicated pCR and non-pCR in 32 (47.8 %) and 35 (52.2 %) patients. There were significant predictors for pCR in univariate (Clinical N: OR 2.83, p=0.043; HER-2: OR 4.80, p=0.002; TILs-US score: OR 2.83, p=0.04) and multivariate analyses (HER-2: OR 6.42, p=0.009) in all breast cancer. There were not significant predictors for pCR in univariate and multivariate analyses in triple negative breast cancer. While, there were significant predictors for pCR in univariate (TILs-US score: OR 17.5, p=0.002) and multivariate analyses (TILs-US score: OR 82.8, p=0.02) in HER2 positive breast cancer

Conclusions
In patients with HER2 positive breast cancer, TILs-US score can predict the therapeutic effect in neoadjuvant chemotherapy (NAC) and help with the development of appropriate treatment plans.
The efficacy of preoperative pathological features to improve diagnosis accuracy in lymph node metastasis by axillary ultrasound

Rintaro Koike¹, Takashi Fujita¹, Naohiro Sata¹, Mikio Shiozawa¹, Chieko Miyazaki¹, Masako Sakuragi¹, Satomi Shiba¹ and Yumiko Tanaka¹. ¹Jichi Medical University Hospital, Shimotuke, Yakushizi, Japan.

Purpose
Recently a sentinel lymph node biopsy has been a part of standard surgical procedure instead of an axillary dissection with a mastectomy for breast cancers. It is necessary to make an accurate diagnosis of lymph node metastasis for deciding surgical procedure either a sentinel lymph node biopsy or an axillary dissection. Preoperative ultrasound is one of widely used tools to make a diagnosis of sentinel lymph node. This study presents results regarding preoperative pathological features to improve diagnosis accuracy of sentinel lymph node by preoperative axillary ultrasound.

Materials and methods
One doctor performed preoperative ultrasound. He used HITACHI HI VISION Ascendus. Axillary lymph node metastasis was suspected when these findings were observed such as partial thickening of lymph node cortex, loss of lymph nodes' hilum, circular swelling shape change and difference compared to a contralateral axillary lymph node. When we suspected axillary lymph node metastasis, we performed fine needle aspiration cytology except other findings such as CT, MRI or physical appearance showed obvious axillary lymph node metastasis. Preoperative core needle biopsies were performed to determine pathologic types and hormone characters. Clinical cases such that ductal carcinoma in situ, lobular carcinoma and ones with primary systemic treatment (neoadjuvant therapy) were excluded from statistical analysis.

Results
During a study period between April 2015 and December 2017, altogether 662 patients were participated in this study. 304 cases were analyzed by statistical analysis. 268 cases were diagnosed as negative and 36 case as positive in axillary lymph node metastasis by preoperative ultrasound. In the 268 cases 225 cases were diagnosed as negative by sentinel lymph node biopsy during operations (84.0%) but 43 cases were diagnosed as positive (16.0%). 23% cases included less than 20mm micro metastasis (10/43). To investigate correlation between false negative ratio of axillary lymph node metastasis diagnosed by an ultrasound and preoperative pathological features such as hormone receptor, HER2, Ki-67, nuclear grade and subtypes (Luminal, Her2 and triple negative). The false negative ratio was 17.0% vs 11.1% in hormone receptor (positive vs negative, p = 0.434), 14.5% vs 16.0% in HER2 (positive vs negative, p = 0.887), 15.4% vs 19.1% in Ki-67 (<20% vs ≥20%, p = 0.441), 18.4% vs 9.38% in nuclear grade (1 vs 2 and 3, p = 0.997), 11.3% vs 23.8% vs 16.7% vs 16.7% (Luminal A vs Luminal B vs Her2 vs triple negative, p>0.05).

Conclusion
There were no statistical significant difference between the axillary lymph node metastasis diagnosed by an ultrasound and the preoperative pathological features. However cases categorized in Luminal B by preoperative pathology had relatively high false negative ratio of axillary lymph node metastasis diagnosed by an ultrasound. It is necessary to investigate a way to improve diagnosis accuracy of sentinel lymph node by a preoperative axillary ultrasound.
Hand-held impulse-radar detector for breast cancer: development and a pilot study

Shinsuke Sasada¹, Norio Masumoto¹, Hang Song¹, Noriko Goda¹, Keiko Kajitani¹, Akiko Emi¹, Takayuki Kadoya¹, Koji Arihiro¹, Takamaro Kikkawa¹ and Morihito Okada¹. ¹Hiroshima University, Hiroshima, Japan.

**Background:** Microwave breast imaging, which using the difference in the dielectric properties between breast cancer and normal breast tissue, is a painless and non-radiation method. We have created a novel hand-held prototype of breast cancer detector using impulse-radar based imaging system, and conducted a pilot clinical study.

**Methods:** The detector consists of complementary metal-oxide-semiconductor (CMOS) integrated circuits covering the ultrawideband width from 3.1 to 10.6 GHz, which enable the generation and transmission of Gaussian monocycle pulse (GMP) trains and single port eight throw switching matrices (SP8T-SW) for controlling a 4×4 cross-shaped dome antenna array. The size of the detector was 19.1 × 17.7 × 18.8 cm. After evaluation using a breast tumor phantom and the resected breast specimens obtained through mastectomy, we recruited 5 patients with histologically confirmed breast cancers in the clinical study. The detector was placed on the breast with the patient in a supine position. The primary endpoint was a detection rate of breast cancers, and the secondary endpoints were positional accuracy and adverse event. This study was registered with the UMIN Clinical Trials Registry (UMIN000026181).

**Results:** The three-dimensional positions of the tumors in the imaging results using a phantom and resected specimens are consistent with the results of histopathology analysis. In the clinical study, all 5 targeted breast cancers were detected and were visualized at the sites confirmed by other diagnostic modalities. Among 5 tumors, one was not detected via mammography because of heterogeneously dense breast and another was a microinvasive carcinoma of invasive tumor size 0.5 mm. No study-related adverse events occurred.

**Conclusions:** We succeeded in creating a new device of hand-held impulse-radar detector for breast cancer. The detector has sufficient detective capability, is safe for clinical use, and might detect an early stage breast cancer. In the future, we will proceed with the development to clinical application.
Hepatic complications of breast cancer

Margaret J Wong¹ and Hailey Choi². ¹Stanford University, Stanford, CA and ²University of California, San Francisco, San Francisco, CA.

Background
Breast cancer is the most common malignancy and the leading cause of cancer death in women in the United States. Nearly 30% of women with metastatic breast cancer will have liver metastases, with a median survival from time of 4.23 months from time of metastatic diagnosis. Hepatic involvement of breast cancer is common and can result from metastatic tumor burden or treatment with chemotherapy or radiation. Being able to recognize and diagnose hepatic involvement of breast cancer is of utmost importance, as it has a dramatic effect on patient prognosis and management.

Learning Objectives
To familiarize multidisciplinary clinical team members with the radiographic presentations of hepatic complications of breast cancer in a variety of imaging modalities including computed tomography, dual-energy computed tomography, ultrasound, and MR. This will facilitate accurate and prompt diagnosis and treatment of hepatic involvement of breast cancer.

Abstract
Our educational pictorial essay demonstrates the typical appearance of hepatic metastases on multiple imaging modalities, as well as atypical presentations such as hyperdense, hypervascular, or hypoechoic lesions and pseudoprogression. We will show examples of hepatic metastases presenting as pseudocirrhosis, left lobar atrophy, capsular retraction, as well as sequelae of pseudocirrhosis such as malignant ascites, varices, portal vein thrombosis, and biliary obstruction. We will discuss the radiographic appearance of the liver after being treated with locoregional liver-directed techniques such as surgical resection, ablation, and chemoembolization. Importantly, we will illustrate examples of hepatic complications from systemic therapy including steatohepatitis from tamoxifen, as well as hepatic fibrosis from gemcitabine.

Conclusion
Clinicians must have a thorough understanding of the hepatic complications of cancer to ensure excellent diagnostic accuracy and management.

Machine learning based analysis of CT radiomics for the simultaneous indeterminate pulmonary nodules of breast cancer

Qin Xiao¹, Yajia Gu¹, Jiong Wu¹, Zhe Wang² and Yan Huang¹. ¹Fudan University Shanghai Cancer Hospital, ShangHai, China and ²Fudan University Shanghai Center for Mathematical Sciences, ShangHai, China.

PURPOSE: To investigate texture features of simultaneous indeterminate pulmonary nodules of breast cancer for predicting their potential metastasis.

METHODS AND MATERIALS: 150 patients with simultaneous breast cancer diagnosed by biopsy and pulmonary nodules (diameter: 5-20mm) detected by preoperative CT were enrolled in this study. After surgery and breast cancer treatment, the patients were followed up for at least half a year or longer by CT to observe the changes of lung nodules, thereby inferring the potential of metastasis. We classify pulmonary nodules into two groups: the reduced or enlarged pulmonary nodules were defined as highly metastasis possibility (Group 1), and long-term stable pulmonary nodules were defined as low metastasis possibility (Group 2). In addition, pathologic proven primary lung cancer in this study (Group 3) was compared with Group 1. Therefore, we carried out a comparative analysis of the texture features between the groups, and additional statistical were used three regression testing to extract texture features. Finally, we construct a machine learning classifier and calculate the accuracy of cross-validation.

RESULTS: We collected 106 features by the texture analysis(TA). There are 18 features with significant differences between Group 1 and the Group 2(\(p<0.05\)), and 76 features with significant differences in the Group 1 and Group 3(\(p<0.05\)). We tried to find key features related to pathology in 106 features using three methods: lasso regression, ridge regression and forward stepwise regression. The accuracy in different regressions respectively is 94.5%, 94.5%, 89.7% using KNN between Group 1 and Group 2. The accuracy in different regressions respectively is 96.2%(KNN), 96.2%(Tree), 92.3%(Linear Discriminant) in the Group 1 and Group 3.

CONCLUDES: The identified radiomics features have the potential to be used as a biomarker for metastasis prediction of simultaneous indeterminate pulmonary nodules in breast cancer patients, and it may contribute to preoperative treatment and postoperative follow-up planning.
Development of patient-derived xenograft tumor model with organ-specific metastatic potential for evaluation of new therapeutics for hormone receptor-positive advanced breast cancer

Wenan Qiang1,2,3, Zhangfeng Zhong1, Lorenzo Gerratana3, Youbin Zhang3, Qiang Zhang3, Demirkan Gursel3, Jian-Jun Wei3, Reiner Bleher2, Charles James1,2, Thomas O'Halloran1,2 and Massimo Cristofanilli3.

1Center for Developmental Therapeutics, Northwestern University, Evanston, IL; 2Chemistry of Life Processes Institute, Northwestern University, Evanston, IL and 3Feinberg School of Medicine, Northwestern University, Chicago, IL.

Background: Breast cancer (BC) is a heterogeneous disease with most common metastatic sites of liver, lung, brain, and bone. Endocrine resistance in hormone receptor-positive (HR+) advanced BC (ABC) cancer is a clinical challenge. ESR1 mutations are a key mechanism in acquired resistance, primarily occurs after exposure to endocrine therapy such as aromatase inhibitors but also selective estrogen modulators and degraders (i.e. Tamoxifen and Fulvestrant). Circulating tumor cells (CTCs) enumeration is a prognostic biomarker in ABC but the relation between the onset of ESR1 mutations and CTCs status is still unclear. Aim of this project is to define the clinical behavior of ESR1 mutated ABC in terms of metastasizing potential, through CTC enumeration and pattern; and to establish ESR1 mutated HR+ ABC PDX models able to recapitulate these characteristics.

Methods: CTCs and circulating tumor DNA (ctDNA) were characterized in 55 HR+ ABC patients. ESR1 mutations status from 55 patient plasma cell-free DNA were generated using Guardant Next Generation Sequencing. Samples were also examined for numbers of CTCs by CellSearch. Association of ESR1 mutations with sites of distant organ metastasis and with CTC enumeration was analyzed by Chi square test and Kruskal–Wallis test, respectively. In preclinical model development, six samples of pleural effusion-derived tumor cells from Stage IV HR+ ABC patients were collected to establish HR+ ABC with ESR1 mutation PDX tumor model and its derived 3D organoid/spheroid cultures.

Results: ESR1 mutations were identified in 10 out of 55 patients (4 Y537S variant and 3 D538G variant, 4 other variants, 1 patient with both variants). In 55 patients, 72 visceral vs 27 bone metastatic incidences were observed; the data indicated 9 observed vs 4.5 expected in ESR1 mutated and 16 observed vs 20.5 expected in wild type (WT) (P=0.003) for liver metastasis; 10 observed vs 7.1 expected in ESR1 mutated and 29 observed vs 31.9 expected in WT (P=0.026) for bone metastasis. Further liver metastasis analysis of individual hot spot mutation site indicated 4 observed vs 1.8 expected in Y537S and 21 observed vs 23.2 expected in WT (P=0.037); and 3 observed vs 1.4 expected in D538G and 22 observed vs 23.6 expected in wild type (P=0.088). The analysis of correlation/distribution between CTCs numbers and ESR1 mutated suggested CTCs median of 13 (IQR 7-49) in ESR1 mutated and 0 (IQR 0-4) in WT HR+ patients (P=0.0044). Four ABC PDX tumor models were developed in immunodeficient NSG female mice demonstrated by pathology to have highly heterogeneous characteristics and metastatic features of the origin patient tumor, in particular, breast fat pad xenografted PDX tumor can result in metastasis to liver and lung tissue. In addition, two patient 3D tumor organoid/spheroid cultures were successfully established.

Conclusions: ESR1 mutated ABC is associated with more aggressive (Stage IV) clinical behavior demonstrated by association with visceral metastases and CTCs detection. ESR1-mutated PDX models recapitulate aggressive features of the disease and can be used for preclinical testing of novel agents in endocrine resistant disease.
Budesonide and colesevelam reduce neratinib-induced diarrhea in a rat model

Joanne M Bowen¹, Kate R Secombe¹, Imogen A Ball¹, Joseph Shirren¹, Anthony D Wignall¹, John W Finnie², Elizabeth Olek³, David Martin³, Alshad S Lalani³ and Dorothy Keefe¹. ¹Adelaide Medical School, University of Adelaide, Adelaide, Australia; ²SA Pathology, Adelaide, Australia and ³Puma Biotechnology Inc., Los Angeles, CA.

Background: Neratinib (Puma Biotechnology Inc.) is an irreversible pan-HER tyrosine kinase inhibitor approved for use as extended adjuvant therapy in women with early-stage HER2+ breast cancer. Diarrhea is the main adverse event of neratinib; grade 3 events are common in the absence of antidiarrheal prophylaxis (40%) [Chan et al. Lancet Oncol 2016]. To investigate the underlying pathogenic mechanisms and to explore possible targets for its prevention, we developed a reproducible rat model of neratinib-induced diarrhea. Findings from the model indicated that neratinib-induced diarrhea is multifactorial, involving anatomical disruption and mucosal inflammation in the ileum and colon [Secombe et al. Asia Pac J Clin Oncol 2017]. We investigated the effects of budesonide, a locally-acting corticosteroid used for gastrointestinal conditions, and colesevelam, a bile acid sequestrant, on neratinib-associated diarrhea and intestinal changes in this model.

Methods: Male albino Wistar rats were randomly allocated to vehicle control (5% DMSO/1% carboxymethyl cellulose), neratinib 50 mg/kg alone or combined with budesonide 1 mg/kg or colesevelam 300 mg/kg by oral gavage for 14 or 28 days. Diarrhea severity was graded daily [0, no diarrhea; 1, mild; 2, moderate; 3, severe]. A tissue injury score was assigned based on validated histological criteria (villus fusion and atrophy, disruption of brush border and enterocytes, crypt losses/architectural disruption, crypt cell disruption, infiltration of polymorphonuclear cells/lymphocytes, dilation of lymphatics/capillaries, edema). Inflammation was assessed using multiplex cytokine/chemokine ELISA. Fecal bile acids were measured in pooled fecal samples over an 8-hour period.

Results: Findings at 28 days:

Conclusions: Budesonide and colesevelam reduced duration of neratinib-induced diarrhea and prevented severe diarrhea. Budesonide also reduced histopathological injury and inflammation via preservation of intestinal morphology and upregulation of anti-inflammatory cytokines in the ileum and colon. The phase II CONTROL study (Clinicaltrials.gov NCT02400476) is currently investigating the effects of adding budesonide or colestipol to loperamide prophylaxis in the prevention of neratinib-induced diarrhea and will help to determine the clinical relevance of our observations.
Successful development of patient-derived orthotopic xenograft models of brain and lung metastases of human breast cancer

Masanori Oshi¹, Maiko Okano¹ and Kazuaki Takabe¹. ¹Roswell Park Comprehensive Cancer Center, Buffalo, NY.

**Background:** Metastatic breast cancer is the reason that we continue to lose 40,000 women every year in the US. Without appropriate pre-clinical model, success rate of clinical trials continue to suffer. Because syngeneic mouse models utilize murine neoplasm that may not represent human cancer, patient-derived xenografts (PDX) have emerged as a pre-clinical model that maintains human cancer features such as intratumoral heterogeneity. However, there is no established orthotopic PDX model for metastatic breast cancer even though the main cause of death is brain and lung metastasis. Orthotopic brain or lung PDX is expected to reproduce the original tumor microenvironment. We describe our new patient-derived metastasis orthotopic xenograft (PDMOX) mouse models of human breast cancer.

**Methods:** All work was performed in female NSG mice of age 8-12 m. Breast cancer metastatic tumors from brain and lung that had been passed 3x in mammary fat pads were used. Tumors of 1 mm³ were implanted orthotopically in two forms: solid piece, or minced tissue with 3 µl Matrigel. Tumor growth was monitored by MRI.

**Results:** Two methods for brain PDMOX were compared. “Manual push” method implanted minced tumor through a frontal bone burr hole into right caudate putamen at 4 mm depth using forceps. “Pipette tip” method utilized either a pipetter for minced tissue or Hamilton syringe for solid tissue to inoculate tumor. One hour post-surgical survival was 37.5% (3/8) after “manual push”, and 100% (30/30) after “Pipette tip” method. All tumors engrafted in surviving mice with either method. However, the tumors formed on brain surface and parenchyma invasion was rare after “manual push” method, whereas solid tumor invaded parenchyma by “pipette tip” method. Therefore, it was no surprise to find large variation in tumor growth after “Manual push” (detection time 17±5.0 d, range: 17-26; volume 5.6±21.0 mm³, range 2.8-48.7). One mouse developed ptosis, and 2 out of 3 mice that underwent “Manual push” had sudden death. On the other hand, all mice that underwent “Pipette tip” method lived until tumor grew to 125-200 mm³, without neurological symptoms. These brain tumors could be passaged with 100% success (9/9). For right lung PDMOX, “thoracotomy” and “non-thoracotomy” methods were compared. “Thoracotomy” method implanted a solid tissue using forceps or 8-0 nylon suture, or injected minced tissue 1 mm below pleura. “Non-thoracotomy” method injected minced tissue using 23G needle. One hour post-surgical survival was 30% (9/30, 8/30) after “thoracotomy” method using forceps or suture, resp. However, survival using suture method could be significantly improved to 97% (29/30) by reducing thoracotomy length (<10 vs. ≥10 mm: t test P = 0.003). Post-operative survival was not affected by age, weight, or operation or anesthesia time. On the other hand, all mice after “non-thoracotomy” method survived, but chest wall implantation occurred in 67% (4/6) when the method was performed using a cell line.

**Conclusion:** By simple modifications of surgical techniques, we could establish orthotopic brain and lung xenografts of breast cancer tumors with almost zero mortality and 100% engraftment. Our novel PDMOX models can be powerful tools for preclinical studies.
The role and mechanism of active vitamin D mediated by Bmi-1 in inhibiting the allograft growth and bone metastasis of breast cancer

Lu Guangping1,2, Li Wei1, Huang Xiang1, Jin Shidai1, Miao Dengshun3, Fu Ziyi1,4, Tang Jinhai1 and Yin Yongmei1. 1The First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China; 2The Dongtai Affiliated Hospital of Nantong University, Dongtai, Jiangsu, China; 3State Key Laboratory of Reproductive Medicine, The Research Center for Bone and Stem Cells, Nanjing Medical University, Nanjing, Jiangsu, China and 4Nanjing Maternal and Child Medical Institute, Affiliated Nanjing Maternity and Child Health Care Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.

Background: Breast cancer is a common female malignancy and bone is the most common distant metastasis organ, which seriously affects the quality of life of patients. An ongoing clinical study shows that vitamin D deficiency is a common risk factor for bone metastases in breast cancer. However, the mechanism has not been reported.

Objectives: 1) To clarify the role of active vitamin D in inhibiting breast cancer cell growth and bone metastasis; 2) To clarify the role of active vitamin D mediated by Bmi-1 in inhibiting the allograft growth and bone metastasis of breast cancer; 3) To reveal the mechanism of action of active vitamin D in inhibiting the occurrence and metastasis of breast cancer.

Methods: A murine breast cancer TM40D cells were treated with 1,25(OH)2D3, the proliferation, migration and invasive ability were examined using CCK-8 assay, scratch test, and transwell assay, respectively. The TM40D cells were transplanted into tibiae of WT or Cyp27b1-/- female mice treated with or without exogenous 1,25(OH)2D3, the phenotype of bone metastases was analyzed using imaging and histopathological methods. A TM40D stably transfected with Bmi-1 knockdown cell line was established. The effects of Bmi-1 knockdown on the proliferation, migration, and invasion of TM40D cells were examined; TM40D cells transfected with an empty vector or a Bmi-1 knockdown were transplanted into the subcutaneous or upper tibial medullary cavity of WT or Cyp27b1-/- mice, treated with or without exogenous 1,25(OH)2D3, and the phenotypic changes of transplanted tumors and bone metastases were analyzed.

Results: 1) 1,25(OH)2D3 inhibited the proliferation, migration and invasive ability of TM40D cells in vitro; 2) 1,25(OH)2D3 inhibited the tumor growth and osteolytic bone destruction in vivo; 3) 1,25(OH)2D3 inhibited osteoclastic bone resorption induced by TM40D; 4) 1,25(OH)2D3 can significantly down-regulate the Bmi-1 expression in breast cancer cells in vivo and in vitro; 5) Bmi-1 knockdown inhibited proliferation and promoted senescence by elevating the expression levels of P16, P19, and P53, and inhibited the allograft growth; 6) Bmi-1 knockdown suppressed the proliferation, migration and invasive ability of TM40D cells; 7) Bmi-1 knockdown suppresses osteolytic bone destruction in vivo; 8) Exogenous 1,25(OH)2D3 and Bmi-1 knockdown both upregulated the expression of tumor suppressor genes in vivo.

Conclusions: The results indicate active vitamin D can inhibit the occurrence of breast cancer and bone metastasis by down-regulating Bmi-1, activating of P16/Rb and P19/P53 signaling pathways, inhibiting breast cancer cell proliferation and growth in bone tissue, inducing breast cancer cell senescence, and reducing osteolytic bone destruction. The results not only revealed the mechanism of action of active vitamin D in inhibiting the occurrence and metastasis of breast cancer, but also provided experimental and theoretical basis for the clinical application of active vitamin D in the prevention and treatment of breast cancer and its bone metastases.
Androgen supplementation in patient derived xenografts in androgen receptor positive breast cancer to increase engraftment and growth rate

Verena Imke Isabel Kiver1,2, Annika Wulf-Goldenberg4, Philipp Sebastian Jurmeister1,3, Caroline Schweiger1,5,6, Olga Gorea1,2, Jens Hoffmann4, Carsten Denkert3,5,6, Ulrich Keilholz1,5,6, Cornelia Liedtke2 and Jens-Uwe Blohmer2. 1Charite Comprehensive Cancer Center, Berlin, Germany; 2Charite Institute of Gynecology with Breast Center, Berlin, Germany; 3Charite Institute for Pathology, Berlin, Germany; 4Experimental Pharmacology & Oncology Berlin GmbH-Berlin-Buch, Berlin, Germany; 5German Cancer Consortium (DKTK), Berlin, Germany and 6German Cancer Research Center (DKFZ), Heidelberg, Germany.

Background:
The European fund for regional development (EFRE) supported Precision Oncology and Personalized Therapy Prediction (POP) Project is establishing preclinical models to further the development of personalized therapy options. In the subgroup breast cancer the current goal is to increase the growth and engraftment rates of breast cancer patient derived xenografts (PDX) models.

Methods:
Breast cancer patients of the Department of Gynecology with Breast Center Charité Universitätsmedizin Berlin, Germany are recruited since May 2017. In total 29 tissue samples were collected and included so far. Treatment naive and treatment refractory patients, triple negative breast cancer (TNBC), hormone receptor positive (HR+) and Her2 postivie tumors, primary disease, recurrence or metastasis are sampled. Fresh tumor tissue is extracted via surgery or biopsy. The materials are then implanted into female immunodeficient NOG mice. To establish PDX models for HR+ breast cancer the mice received estrogen supplementation.

To increase engraftment and growth rates androgen receptor (AR) testing and subsequently androgen replacement was started since April 2018.

Up to date, 6 new samples have been collected. One HR+ and two TNBC samples tested also positive for AR. These samples are currently in passage 0 (p0) and are now supplied with androgens to increase engraftment and growth rate. One already established AR+ TNBC PDX is being regrown with androgen supplementation to compare growth rates.

Results:
Out of the initial 23 tissue samples ten (six HR+ and four TNBC) have been able to be engrafted into PDX mice. The TNBC PDX models are one in p1, one in p2, one in p3 and one is being tested with systemic therapy. Engraftment time in p1 were between 19 and 97 days. Growth time to passagable size between 21 and 112 days.

The HR+ PDX models are four in p1 and two in p2. Engraftment time in p1 was between 26 and 123 days. Growth time to passagable size has been achieved in 2 HR+ PDX within 17 to 48 days.

The engraftment/growth rates and times of the androgen supplemented PDX models will be presented.

Conclusion:
Breast cancer growths in humans slowly and this is also the case in the PDX models. To achieve faster growth and higher engraftment rates androgen supplementation in AR+ breast cancer might be an additional enhancive factor.
Identification and targeting of clinically actionable genes in bone metastases

Rebecca J Watters¹, Beverly Hersh¹, Margaret Hankins¹, Vai Patel¹, Benjamin Martin¹, Zhong Li¹, Karen L Clark¹, Alessandro Pirosa¹, Nolan Priedigkeit¹, Kurt R Weiss¹, Adrian V Lee¹, Rocky S Tuan¹, Peter G Alexander¹ and Steffi Oesterreich¹. ¹University of Pittsburgh, Pittsburgh, PA.

BACKGROUND: The most common site of cancer metastases from breast is to bone, which occurs in 65-80% of patients resulting in significant comorbidities caused by pathological fractures, pain, hypercalcemia, and nerve compression. The current standard of care involves surgery, radiation, and treatment with bisphosphonates to target osteoclast driven resorption. These modalities all have limitations, complications, and cannot prevent new bone metastases from developing. There is an obvious unmet need for new therapeutic targets and models to treat and study breast cancer related bone metastasis. A large portion of breast cancer research utilizes cell lines and animal models with tissues taken from early stage, primary breast cancers. Furthermore, endpoints such as tumor size reduction and growth in these studies do not always translate to tumor spread. As a result, these study endpoints are not relevant for individuals that are already living with metastatic disease.

MATERIALS and METHODS: Potential therapeutic targets involved in metastasis and osteomimicry were identified by performing exome-capture RNA-sequencing (ecRNA-seq) on eleven matched primary breast tumor and bone metastases. Expression gains and losses were identified from the clinically actionable gene set obtained using the Drug Gene Interaction Database (DGBIdB 2.0). A unique organotypic bone model comprised of endothelial cells (EC), osteoblasts (OB), and mesenchymal stem cells (MSC) co-cultured with primary metastatic bone samples from breast cancer patients is being utilized to target these genes of interest.

RESULTS: ecRNA-seq of metastatic bone samples revealed expression gains in genes of interest (GOI): EPH Receptor A3 (EPHA3), Protein Tyrosine Phosphatase, Receptor Type D (PTPRD), Patched 1 (PTCH1), and Platelet Derived Growth Factor Receptor Alpha (PDGFRA). The GOI were highly recurrent in patients with endocrine-resistant disease that had developed bone metastases after treatment but were absent in the de novo bone metastasis cases where patients had not yet received endocrine therapy. Analysis for expression of these GOI as well as osteomimicry genes are being assessed in our organotypic bone model.

CONCLUSIONS: The GOI identified in this study have been previously associated with the growth and progression of cancer. Furthermore, these genes may be regulated by the RB1-E2F pathway, which was also found to be upregulated in these same samples, and previous studies have linked this pathway's ability to either directly or indirectly regulate our GOI expression levels. Targeting $EPHA3$, $PTPRD$, $PTCH1$, and $PDGFRA$ in breast cancer recurrences may provide a novel therapeutic approach to treat bone metastases that have developed endocrine resistance in patients. Our organotypic bone scaffold provides a unique model to study the interactions of breast cancer cells with bone cells and to test inhibition of novel target genes. Future development of this model will provide a tool for high-throughput screening of drugs to target bone metastases of breast cancer.
Evaluation of breast cancer intratumor heterogeneity and its implications to the therapeutic agents with organoids subclones

Bailin Zhang¹, Xiaozhou Xu¹, Haifeng Cai² and Zhijian Sun³. ¹National Cancer Center China, Beijing, China; ²TangShan People’s Hospital, TangShan, Hebei, China and ³K2 Oncology Co.Ltd, Beijing, China.

Background: Breast cancer is the second most common cancer in women, accounting for 15.3% new cancer cases and 6.7% cancer death in 2018. Chemotherapy, target therapy and endocrine therapy are main strategies for breast cancer treatment after surgery to prevent cancer recurrence and metastasis. The choice of these strategies is mainly based on the molecular and pathological markers as well as experience from clinicians. However, due to the heterogeneity of intra-tumor and also between different patients, it is hard for clinicians to make the best therapeutic regimen to target all the cancer sub-population at current stage. Developing more precise and personalized chemotherapy strategy for individual patient would be of great importance. Cancer organoids, established based on in vitro 3-D culture techniques, were demonstrated to largely retain the biological characteristics of tumors from patients, and made it possible to assess the responses to various strategies for individual patient. Comparing with other cancer type such as colon cancer, breast cancer organoids study was relatively immature. This study was designed to efficiently establish breast cancer organoids from clinical patients and further test the sensitivity of these organoids to therapeutic agents.

Methods: Fresh breast cancer tissues from patients were dissected into small pieces and subjected to enzyme digestion to prepare a single cell suspension. Organoids were established from the single cell suspension in Matrigel and modified PDTO culture medium. Organoid clones derived from various cancer cells were heterogeneous, which were isolated with pipette tips to establish breast cancer organoids subclones. First line chemotherapy drugs such as Docetaxel, Adriamycin, and Fluorouracil, target therapy agents and endocrine therapy drug such as PD-991, Neratinib and Afimoxifene were used to treat each organoid clones. Cell survival rate was measured by CellTiter-Glo Kit and drug sensitivity was assessed by IC₅₀ value.

Results: 23 organoid subclones from 5 patients were successfully established. Drug response (effect) varied to individual organoid subclones from the same patient. Some subclones showed totally resistance while others were sensitive or parcial sensitive to indicated therapeutic agents, indicating the heterogeneity of breast cancer and different intra-tumor subpopulation have distinct drug response. The heterogeneity, especially the resistant subclones put forward to explain the acquired drug resistance and relapse in clinical practice.

Conclusion: Breast cancer organoids are good in vitro models for drug sensitivity screening, which would assist clinicians make better chemotherapy strategy to achieve precise and personalized medication for patients. Moreover, organoid models would also be an ideal platform to help dissect the underlying mechanism of cancer heterogeneity induced drug resistance.
Anticancer potential evaluation of natural products with breast cancer organoids

Bailin Zhang, Xiaozhou Xu, Haifeng Cai and Zhijian Sun. 1National Cancer Center China, Beijing, China; 2TangShan People’s Hospital, TangShan, Hebei, China and 3K2 Oncology Co.Ltd, Beijing, China.

Background: Breast cancer is one of the most malignant diseases threatening the health of our society. It is estimated that there will be more than 300,000 new cases of breast cancer in the US in 2018. Currently, surgery combined with chemotherapy is the most common strategy for breast cancer treatment. However, due to the cancer heterogeneity induced drug resistance, continuously developing new anti-cancer drugs is of great importance. Nature compounds extracted from traditional Chinese herbs were demonstrated to have anti-cancer activity through cell based experiments, but lacking suitable pre-clinical models, which could faithfully reflect in vivo tumor property, prevents these compounds from further characterizing. Now cancer organoids, as a new in vitro 3-D culture technique, were demonstrated to largely retain the biological characteristics of tumors from patients, and potentially served as an ideal platform for drug sensitivity test. Breast cancer organoids study was relatively limited when comparing with other type of cancer such as colon cancer. In this study, we set up system to efficiently establish breast cancer organoids from clinical patients and further test the sensitivity of these organoids to various nature compounds.

Methods: We collected fresh breast cancer tissues from 17 patients after surgery and established organoid models. Different dosage of herb derived nature compounds such as Gypenoside, Berberine, Oxymatdne, Sophoridine, Betaine, Chelerythrine Chloride, Harmine, Cantharidin were used to treat each organoid clone. Luminescent cell viability assay was used to indicate tumor survival rate.

Results: Organoid were successfully established for all 17 patients. A Short Tandem Repeat (STR) analysis was employed to detect sample contamination and HE(hematoxylin and eosin) stain was used to confirm the histological features. All organoids were resistant or slightly response to Oxymatdne, Sophoridine, Gypenosides, Betaine. For Berberine and Cantharidin, 10 out of 17 and 14 out of 17 organoids showed dose-dependent inhibition efficacy respectively, and the rest showed resistance. For Chelerythrine Chloride and Harmine, only organoids from specific patient showed sensitivity in a dose-dependent manner. Interestingly, different patients had distinct response pattern to these nature compounds, indicating organoids were useful in the anti-cancer lead screening and biomarker identification.

Conclusion: Breast cancer organoid, as a wonderful pre-clinical model largely containing tumor in vivo property, provides an ideal platform for new drug discovery and inhibitor screening. Moreover, serving as in vitro replacements for breast cancer, organoid models make it possible to test drug sensitivity for individual patient to achieve precise and personalize medication.
A novel cleaved cytoplasmic lncRNA LacRNA interacts with PHB2 and suppresses breast cancer metastasis via repressing MYC targets

Rong Guo¹,², Yong-Hui Su¹,², Jing-yan Xue¹,², Jing Si¹,², Ya-yun Chi¹,² and Jiong Wu¹,². ¹Fudan University Shanghai Cancer Center, Shanghai, China and ²Fudan University, Shanghai Medical College, Shanghai, China.

Long noncoding RNAs (lncRNAs) have been implicated in breast cancer metastases through largely unknown mechanisms. In this study, we used microarray analysis to compare lncRNAs expression levels between matched pairs of breast lymph node metastatic tissues and primary tumors. We discovered that lncRNA LINC00478 was substantially downregulated in the metastatic tumor samples. Interestingly, we found that LINC00478 could be cleaved by RNase to simultaneously generates the mature 5’ ends of cytoplasmic RNA and 3’ ends of nuclear RNA by polyadenylation. We named 5’ ends 791-nt RNA as LacRNA (LINC00478-asscociated cytoplasmic RNA). Over expression of full-length LINC00478 and LacRNA, but not LINC00478 3’ RNA, significantly inhibited breast cancer proliferation, invasion and metastasis in vitro and in vivo. We used CRISPR-dCas9 complex to mediate efficient transcriptional activation of LacRNA at endogenous genomic loci followed by RNA-seq analyses. Gene set enrichment analysis (GSEA) showed that the MYC pathway/targets were prominent gene sets negatively enriched in LacRNA-activated cells. Further study revealed that LacRNA exerted its tumor suppressive activity by directly binding with prohibitin2(PHB2) to enhance its protein stability, which promoted PHB2 competing with MYC for transcriptionally suppressing the MYC target genes (e.g., CDC20, CDC45, CCNA2 and MAD2L1). Mechanistically, LacRNA inhibits breast cancer invasion and metastasis by interacting with PHB2 through LacRNA’s 1-300nt region. In addition, taking advantage of CRISPR system to knock-out and activate the expression of LacRNA, as well as rescue experiment, we uncovered the positive correlation between LacRNA and PHB2 and their role in suppressing MYC target genes and cancer metastasis. At the same time, LacRNA can attenuated the MYC induced activation of MYC targets through binding with PHB2, indicating that LacRNA plays a central role in the suppression of MYC target genes. We further explored the role of LacRNA in inhibiting lung metastasis by implanting LacRNA-activated LM2 cells into the mammary fat pads of NOD-SCID mice. Luciferase imaging and histological analysis were used to detect lung metastasis and found that LacRNA significantly suppressed lung metastasis. Immunohistochemistry were used to detect the expression of PHB2 and MYC targets in both orthotopic tumors and lung metastasis and verified their correlation in vivo. Extensive analyses of clinical data indicated that LacRNA level was substantially downregulated in metastases tumors accompanied by enrichment of MYC targets. The robustness value of LacRNA expression was further verified in two independent patient cohorts, including 530 invasive breast cancer tumors in Fudan University Shanghai Cancer Center (FUSCC) and 819 breast patients’ data from TCGA. High LacRNA expression level had a significantly better clinical outcome in both cohorts and represented an independent prognostic predictor for DFS (HR=0.48, P=0.006, multivariate analysis) and OS (HR=0.32, P=0.009, multivariate analysis) in FUSCC cohort. Collectively, LacRNA functions as a tumor suppressor lncRNA that inhibits breast cancer invasion-metastasis cascade.
Identification of microRNAs differentially expressed in brain metastasis secondary to breast cancer

Athina Giannoudis¹, Kim Clarke², Rasheed Zakaria²³, Damir Vareslija¹, Mosavar Farahani¹, Lucille Rainbow², Angela Platt-Higgins², Stuart Ruthven⁵, Katherine Brougham⁵, Phillip S Rudland³, Michael D Jenkinson¹³, Leonie Young⁴, Francesco Falciani² and Carlo Palmieri¹⁶. ¹University of Liverpool, Institute of Translational Medicine, Liverpool, United Kingdom; ²University of Liverpool, Institute of Integrative Biology, Liverpool, United Kingdom; ³The Walton Centre NHS Foundation Trust, Liverpool, United Kingdom; ⁴RCSI Surgery, Royal College of Surgeons in Ireland, Dublin, Ireland; ⁵Royal Liverpool University Hospital, Liverpool, United Kingdom and ⁶The Clatterbridge Cancer Centre NHS Foundation Trust, Wirral, Bebington, Wirral, United Kingdom.

Background: Despite sequential improvements in the adjuvant treatment of breast cancer (BC), recurrence and metastasis remains a major clinical problem and in particular, brain metastasis (BCBM). A number of microRNAs (miRNAs) have been linked to the metastatic process in BC, but to date there is limited work on the microRNAs involved in BCBM. The current study aim to identify differentially expressed miRNAs within primary breast cancer who did not recur (BCNR) versus primary BC cases which did recur (BCR) and their matched BCBM cases.

Methods: Formalin-fixed paraffin-embedded (FFPE) material was collected of 12 primary BCNRs from the Liverpool tissue bank and of 40 paired primary BCR samples and their matched BCBM from the Walton Research Tissue Bank and RCSI National Breast Cancer Bioresource. miRNA was extracted (Qiagen miRNeasy FFPE kit) and profiled using the NanoString™ nCounter™ miRNA Expression Assay (Human v3 miRNA). The differentially expressed miRNAs between BCNR versus BCR and BCR versus their matched BCBM were identified by significance of microarray analysis (SAM) on the MeV4.9 software. Pathway analysis was performed using the DIANA-mirPath v3.0 software and the Ingenuity Pathway Analysis (IPA) to identify a network of genes/pathways regulated by the differently expressed miRNAs.

Results: 12 BCNR and 30 matched pairs of BCR and BCBM passed the quality control and normalisation processes. Principal component analysis (PCA) performed on 166 miRNAs after QC/normalisation clearly distinguishes the BCNR and the primary BCR from the matched BCBM cases, whereas SAM revealed 58 differentially expressed miRNAs with a 10% FDR (false discovery rate) and an absolute log2 fold-change (FC) >1 between BCNR and BCR and 11 between the matched BCs and BCBMs. Pathway clustering revealed that these differentially expressed miRNAs (10% FDR, log2FC>1) within both BCNR vs BCR and BCR vs BCBM cohorts are highly enriched for genes involved in extracellular matrix (ECM)-receptor interactions, proteoglycans, adherens junctions, TGF-β, p53 and Hippo signalling. IPA identified a network of genes, implicated in the processes of breast cancer invasion and metastasis, regulated by the identified miRNAs, such as, TWIST, MET, TP53, MYC, EZH2, ZEB1, TAGLN and BIRC5. Four of the significantly differentially expressed miRNAs, hsa-miR-132-3p, hsa-miR-199a-5p, hsa-miR-150-5p and hsa-miR-155-5p were present within both cohorts (BCNR vs BCR and BCR vs BCBM) and regulate genes involved in Hippo and TGF-β signalling (DIANA-mirPath v3.0 analysis: p=5.23x10⁻⁸ and p=2.67x10⁻⁷ respectively).

Conclusion: The current study, utilising a large cohort of paired BCR and BCBM cases, provides novel insight into the molecular mechanisms and role of miRNAs in BCBM. Four miRNAs (hsa-miR-132-3p, hsa-miR-199a-5p, hsa-miR-150-5p and hsa-miR-155-5p) in particular could be potentially used to identify patients with increased risk of developing brain metastasis and help facilitate the development of specific treatments for BCBM, which to date have proved elusive. The miRNAs identified require further exploration as potential biomarkers as well as novel therapeutic targets.
Exploring the microRNA landscape of nipple aspirate fluid in the context of mammographic breast density

Cathy B Moelans1, Susana IS Patuleia1, Marije F Bakker2, Elsken van der Wall1, Paul J van Diest1 and Carla H van Gils2.
1University Medical Center Utrecht, Utrecht, Netherlands and 2Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands.

Background
High mammographic density is an established risk factor for breast cancer but studies are needed to elucidate the etiological pathways underlying this relationship. The identification of factors (indirectly) regulating the accumulation of fat and connective tissue may help explain why high mammographic density is linked to breast cancer risk. Those factors may provide markers for predicting and even clues for modifying this risk. MicroRNAs could regulate specific cellular processes involved in regulating mammographic density, like fat accumulation, connective tissue density and immune response. Nipple aspirate fluid represents an excellent opportunity for biomarker detection within the breast microenvironment.

Materials and Methods
MicroRNA expression profiling was performed using TaqMan OpenArray Human MicroRNA Plates (ThermoFisher Scientific) in 40 pooled (paired left and right breast) nipple aspirate fluid samples obtained from age-matched women participating in a population-based breast cancer screening program with 'extremely dense' (n=20) and 'almost entirely fatty' breasts (n=20), without further abnormalities on mammography. Breast density was assessed using Volpara software in categories comparable to American College of Radiology (ACR) breast density categories.

Results
25 significantly differentially expressed microRNAs were identified, including hsa-miR-19a-3p (p=0.001; upregulated in 'extremely dense' versus 'almost entirely fatty'), hsa-miR-324-5p (p=0.003; upregulated), hsa-miR-425-5p (p=0.001; upregulated), hsa-miR-660-5p (p=0.004; upregulated), hsa-miR-29b-3p (p=0.011; upregulated) and hsa-miR-187-3p (p=0.024; downregulated). Based on expression profiles of the 8 most significantly dysregulated microRNAs alone, nipple aspirate fluid samples could reliably be classified into 'extremely dense' and 'almost entirely fatty' mammographic density groups (31/40 (78%) samples correctly classified). Several of the dysregulated microRNAs have been associated with regulation of collagen deposition or crosslinking (e.g. miR-29, miR-222 and let-7) and adipocyte differentiation and proliferation (e.g. miR-29, miR-222, miR-155 and let-7), suggesting that these aberrant miRNAs may play a role in the development of breast tissue with high mammographic density. In addition, pathway enrichment analysis demonstrated an enrichment of the 'proteoglycans in cancer' pathway suggesting that proteoglycan dysregulation is intimately linked to microRNA dysregulation.

Conclusions
In summary, microRNA profiling has resulted in a panel of microRNAs that might help explain why high mammographic density is linked to breast cancer risk and may ultimately result in a biomarker panel for predicting this risk, or provide attractive targets for future breast cancer preventive strategies. Further validation in an independent set of nipple aspirate fluid samples from 'extremely dense' and 'almost entirely fatty' categories is currently ongoing.
NEAT1 enhances drug sensitivity by inhibiting cancer stem-like cells in triple-negative breast cancer

Ava Kwong¹,²,³, Jiawei Chen¹, Jennifer Siu¹, Isabella Chuek¹ and Vivian Shin¹. ¹The University of Hong Kong, Pokfulam, Hong Kong; ²The Hong Kong Hereditary Breast Cancer Family Registry, Shau Kei Wan, Hong Kong and ³Hong Kong Sanatorium and Hospital, Happy Valley, Hong Kong.

Background: Accumulating evidence showed that long non-coding RNAs (lncRNAs) dysregulation is the hallmark of cancer. Nuclear paraspeckle assembly transcript 1 (NEAT1) has been reported to overexpress in many cancers, and promote cell growth and disease progression. However, the role of NEAT1 on drug sensitivity and stem-cell like property in triple-negative breast cancer is largely unknown.

Methods: LncRNA expression profile were compared between breast cancer patients and healthy individuals using lncRNA array. Large scale validation of NEAT1 expression in blood samples were performed by real-time PCR. Triple-negative breast cancer (TNBC) cells, MDA-MB-231 and its cisplatin resistance subline (MDA-MB-231/cis) were used. Stable transfection of cells with NEAT1 knockdown by shRNA, and evaluated single cell clonogenic assay, aldehyde dehydrogenase (ALDH) activity, CD44+/CD24- and other cancer stem cell (CSC) markers. Drug sensitivity assay, flow cytometry analysis, immunofluorescence staining and xenograft model were used to assess the functional role of NEAT1.

Results: Array data showed that NEAT1 was the top upregulated lncRNAs in the plasma of breast cancer patients. Consistent with the array data, validation of larger cohort of patients and healthy individuals (n=369) also demonstrated a higher expression of NEAT1 in breast cancer patients, in particular TNBC subtype. Knockdown of NEAT1 by shRNA sensitized breast cancer cells to cisplatin and taxol treatment. Cell proliferation and colony formation abilities were reduced with S-phase cell cycle arrest in shNEAT1 cells. Flow cytometry analysis revealed an induction of apoptosis with increased cleaved caspase-3. Cells expressing shNEAT1 abrogated ALDH activity, CD44+/CD24- subpopulation and expression of CSC markers (SOX2, NANOG and OCT4). More importantly, shNEAT1 cells retarded tumor growth in xenograft mice model and reduced CSC markers.

Conclusion: Taken together, NEAT1 expression is differentially expressed in breast cancer patients, and particularly higher in patients with TNBC. These findings suggest a potent therapeutic target to improve drug sensitivity in patients with TNBC.
Epigenetic regulation of ER through miR-18a shows ECM activation and identifies poor prognostic subtype within ER+ve HER2-ve breast cancer

Madhumathy G Nair¹, Jyothi S Prabhu¹, Aruna Korlimarla¹, PS Hari¹, Savitha Rajarajan¹, Roma Kaul¹, Annie Alexander¹, Rohini S Raghavan¹, S Rakesh², Marjorie Correa², MSN Prasad³, BS Srinath³ and Sridhar Srinivas Tirumalai¹. ¹St. John’s Research Institute, Bangalore, Karnataka, India; ²St. John’s Medical College and Hospital, Bangalore, Karnataka, India and ³Shankara Cancer Hospital and Research Centre, Bangalore, Karnataka, India.

Introduction
Although endocrine therapy has improved the survival of patients with hormone receptor (HR) positive breast cancer considerably, patients with weaker HR expression tend to have poorer outcomes. There exists significant intra tumoral heterogeneity of ER expression and a recent study suggested that patients with high intra tumoral heterogeneity of ER had an increased long term risk of recurrence (Lindstrom et al JNCI 2018). Multiple reports have supported a role for alterations in microRNA levels having a role in promoting tumor invasion and metastasis. In this study we have explored the epigenetic regulation of ER by microRNA hsa-miR-18a-5p and its role as a prognostic marker in ER positive tumors.

Methods
123 surgically excised specimens of ER positive primary breast cancers were analyzed. Samples were segregated into high and low ER positive groups using 50% positivity as the cut-off. Relative abundance of hsa-miR-18a-5p in these samples was assessed using a TaqMan qRT-PCR. hsa-miR-18a-5p was over-expressed in MCF7 cells using a synthetic mimic and downstream changes in gene and protein expression were assessed using q-RT PCR, immunofluorescence and western blot. Migratory and proliferative ability was assessed using wound healing and MTT assay respectively. Microarray based global gene expression analysis of hsa-miR-18a-5p over-expressing cells was performed. Disease free survival analysis was done using Kaplan-Meier survival analysis.

Result
We estimated the relative abundance of hsa-miR-18a-5p in 123 ER positive primary breast cancers and found the distribution of this miRNA to be highest in the lower ER group (p<0.05). hsa-miR-18a-5p also correlated negatively with ESR1 and PGR (p<0.05). To further probe the role of miR-18a-5p in invasion and metastasis, we over-expressed this microRNA using a synthetic mimic in a luminal cell line MCF7. Microarray analysis revealed an increase in the expression of ECM associated genes, and the Cadherin signalling pathway. We observed a decrease in the expression of luminal genes (PGR, TFF1, GREB1; p<0.05), loss of Tff1 and increase in the levels of basal cytokeratin 14 at the protein level in addition to an increase in proliferative rate of upto 35% (p<0.05). Further, we observed a 15% (p<0.05) increase in the invasive ability by wound healing assay with a significant loss in the levels of E-cadherin protein. In order to study the prognostic importance of hsa-miR-18a-5p, we performed Kaplan-Meier survival analysis and found that stratification of the ER+ve tumor samples by hsa-miR-18a-5p levels produced significant separation of the groups based on disease-free survival (log rank p <0.05). The prognostic value was also validated with multivariate Cox-proportional hazard analysis (Hazard Ratio (HR) of 3.18 (1.07-9.42); p=0.03).

Conclusion
The results from the over-expression of miR-18a-5p in MCF7 cells support the existence of an epigenetic pathway of repression of the luminal phenotype and increased acquisition of traits associated with basal-like and mesenchymal characteristics. It is possible that the over-expression of miR-18a-5p plays a role in patients with poorer outcomes.
Estrogen induced miR-489 acts as a negative feedback to confine uncontrolled estrogen signaling and cell proliferation in breast cancer.

Mithil Soni, Yogin Patel, Ryann Shealy and Hexin Chen. 1University of South Carolina, Columbia, SC; 2Center for Colon Cancer Research, Columbia, SC and 3National Cancer Institute, Surgery Branch, Bethesda, MD.

Estrogen induced miR-489 acts as a negative feedback to confine uncontrolled estrogen signaling and cell proliferation in breast cancer.

Mithil Soni1,2, Yogin Patel1,2,3, Ryann Shealy1, Hexin Chen1,2,4.

1Dept. of Biological Sciences, University of South Carolina, 2Center for colon cancer research, 3current location, National cancer institute, surgery branch, 4corresponding author.

Approximately 75% of diagnosed breast cancer tumors are Estrogen receptor positive tumors and are associated with better prognosis due to response to hormonal therapies. However, around 40% of patients relapse after hormonal therapies. Identification of novel molecular targets is necessary to combat such resistant tumors. In the current study, using microarray, qRT-PCR, western blot, luciferase reporter assay and immunofluorescence, we found that miR-489 is an estrogen regulated miRNA that negatively regulates estrogen signaling. Depletion of miR-489 using Anti-miR-489 siRNA or CRISPR-Cas9 significantly increased estrogen induced proliferation, colony formation ability and stem like cell population. Loss of miR-489 also induced estrogen independent proliferation. Mechanistically we found that depletion of miR-489 enhanced nuclear localization of estrogen receptor while restoration of miR-489 increased cytosolic ER and inhibited estrogen induced transcription. Furthermore, we found that miR-489 depletion also increases estrogen independent growth through activation of MAPK and PI3K-AKT pathway. We also observed loss of miR-489 in tamoxifen resistance breast cancer cell line and found increased resistance to tamoxifen upon miR-489 inhibition while miR-489 restoration sensitized Tamoxifen resistant cell lines. Clinical analysis of estrogen receptor positive breast cancer patient showed that ER+ve breast cancers with low miR-489 expression represents aggressive cancers with significant reduction in survival time. In summary, these results indicate potential role of miR-489 as a biomarker to predict aggressiveness of ER+ve breast cancer and response to tamoxifen therapy and can potentially be used as a therapeutic agent to treat or sensitize tamoxifen resistant tumors.
The effects of microRNA modulation of polo-like kinase 1 in breast cancer cell lines

Nicole Zalles1, Pierluigi Gasparini1 and Carlo M Croce1. 1The Ohio State University Medical Center, Columbus, OH.

BACKGROUND: Elucidating a more universal therapeutic target is key to effectively combat the heterogeneity of breast cancer (BrCa). MicroRNAs (miRs) are small noncoding RNAs that are an abundant class of endogenous regulatory molecules, which act by targeting mRNAs for cleavage and/or translational repression. Continuing studies into BrCa genetics show that the various subtypes of BrCa are also affected by miR activity from the regulation of various cancer-related genes. MiR expression can even influence drug response in multiple cancer types. This prompted our investigation into the nuances of how miRs may influence BrCa behavior and response to treatment with targeted therapies. The Polo-like Kinase 1 (PLK1) enzyme plays an important role in the cell cycle, and is considered to be a proto-oncogene. Inhibiting PLK1 in has shown promise in reducing tumor volume and promoting tumor cell death in various cancers. Understanding how miRs regulate PLK1 in BrCa will improve our understanding of the PLK1 pathway, and whether this miR-directed regulation affects anti-PLK1 therapy. This knowledge could inform future anti-PLK1 BrCa treatment regimens, resulting in better outcomes for patients.

METHODS: The effects of an anti-PLK1 drug, NMS-P937, were tested on triple-negative (TN) (MDA-MB-231, BT549) and luminal (ZR-75-1, CAMA-1) BrCa cell lines. From miRNA target prediction sites (TargetScan, MiRTarBase), a panel of miRs predicted to bind to PLK1 was selected and then assessed using dual-reporter luciferase assays. MiR expression was transiently induced in TN and luminal BrCa cell lines, and the effects were verified using western blotting. Apoptosis was assessed by Annexin V staining in BrCa cell lines transiently transfected with the validated miR and treated with different concentration of NMS-P937 for 48 hrs. To validate the contribution of the miR-PLK1 axis for NMS-P937-induced apoptosis, BrCa cells were transfected with PLK1 siRNA, and the Annexin V staining experiment was repeated.

RESULTS: From the panel of miRs tested, miR-183-5p was the only one to demonstrate binding to the PLK1 gene. Western blotting showed that PLK1 expression was downregulated when miR-183-5p is overexpressed. Annexin V staining suggests that miR-183-5p induces apoptosis through PLK1 targeting in BrCa cell lines, and this effect seems to amplify NMS-P937-induced apoptosis in both cell line subtypes. Apoptotic markers assessed by western blot confirm the over-activation of apoptotic signals by miR-183-5p. Future work will continue to focus on determining the effects of miR-183-5p targeting on pathways downstream of PLK1, and utilizing tumor xenografts to elucidate the effects of miR-183-5p on NMS-P937 response in an in-vivo model.

CONCLUSIONS: MiR-183-5p appears to directly target PLK1 and reduce its level of expression. Additionally, miR-183-5p increases the number of apoptotic BrCa cells when used in combination with NMS-P937, and it is the inhibition of PLK1 specifically that contributes to the increase in the apoptosis of BrCa cells treated with NMS-P937. Taken together, our findings identify a new mechanism of PLK1 modulation through miR. Our next steps will focus on studying these modulatory effects in vivo, in an effort to move forward for clinical applications.
LINC02273 interacts with hnRNPL and promotes metastasis through directly activating AGR2 in breast cancer

Bingqiu Xiu1,2, Yayun Chi1,2,3, Weiru Ji1,2, Qi Zhang1,2 and Jiong Wu1,2,3. 1Key Laboratory of Breast Cancer in Shanghai, Shanghai, China; 2Fudan University Shanghai Cancer Center, Shanghai, China and 3Shanghai Medical College, Fudan University, Shanghai, China.

The prognosis of breast cancer patients with metastasis is still poor even improved by current treatment modalities. Unveiling new biomarkers and molecular mechanisms that underlie metastasis are of vital importance for the treatment of breast cancer. The recent discovery of long noncoding RNAs (lncRNAs) has gained widespread attention. To identify critical lncRNAs that contributed to breast cancer metastasis, we profiled their expression in 5 pairs of primary tumors and lymph nodes metastasis loci by HTA2.0 microarray. LINC02273 is significantly upregulated in metastasis loci and its high expression is associated with poor diseases free survival in a validation set of 254 patients. LINC02273 was mainly located in the cell nucleus. RACE-PCR showed two isoforms and the longest one was the most abundant isoform in breast cancer. Through transwell assay, 3D spheroid invasion assay and mice xenograft metastasis model, we found that LINC02273 promoted breast cancer cell migration, invasion and metastasis. Via mass spectrometry, hnRNPL was found to interact with LINC02273 to enhance its stability, which was further confirmed by Actinomycin D inhibition assay and luciferase reporter assay. Furthermore, ChIRP-seq and ChIP-seq showed that LINC02273 stimulated oncogene AGR2 expression by directly binding to the AGR2 promoter region and increasing H3K27ac modification. Triplex formation assay was performed for verification. We demonstrated that the expression level and oncogenic ability of AGR2 were regulated by hnRNPL through LINC02273. Clinical data and mouse xenograft tumors also revealed the positive correlation of AGR2 and LINC02273. In conclusion, LINC02273, which is stabilized by hnRNPL can promote breast cancer metastasis through upregulation of AGR2 and may serve as a prognostic biomarker for breast cancer.
Exosome microRNA contents are altered during breast cancer progression

Bethany N Hannafon¹, Amy L Gin¹, Fariba Behbod² and Wei-Qun Ding¹. ¹University of Oklahoma Health Sciences Center, Oklahoma City, OK and ²University of Kansas Medical Center, Kansas City, KS.

Background: The progression of breast cancer involves the transformation of normal mammary epithelial cells to ductal carcinoma in situ (DCIS) and invasive breast cancer (IBC). This process is initiated by genetic alterations and characterized by changes to gene expression programs and microenvironmental alterations. However, the specific drivers of DCIS progression to IBC are not well understood nor has an indicator of progression been identified. Exosomes are small secretory vesicles that can contribute to cancer progression by transferring oncogenic factors, such as microRNAs (miRNAs), to surrounding cells in the tumor microenvironment, and enter the circulation to act at distant sites. miRNAs are short noncoding RNAs that regulate the expression of a target messenger RNA (mRNA). Altered regulation by miRNAs is implicated in cancer progression. In this study, we sought to characterize the exosome miRNAs in the MCF10 isogenic model of breast cancer progression in order to identify potential drivers of breast cancer.

Methods: Exosomes were isolated from the conditioned media of the MCF10 isogenic cell line model of breast cancer progression representing the following stages: normal, benign proliferative, carcinoma in situ, and invasive carcinoma. RNA was extracted from the exosomes and next generation RNA sequencing was performed. Exosome miRNA expression was validated in breast cancer cell lines and in plasma exosomes collected from a mouse-intraductal transplantation (MIND) model implanted with MCF10DCIS.com (DCIS) cells that can mimic human DCIS progression in vivo.

Results: Comparisons were made between differentially expressed miRNAs among each condition (fold change >1.5; Kruskal-Wallis p<0.05). Twenty-nine miRNAs were differentially expressed among invasive and DCIS exosomes. The expression of 5 oncogenic miRNAs (miR-30c-5p, -210, -182-5p, -200c-3p, and -200b-3p) were consistently increased, while 2 tumor suppressive miRNAs (miR-423-5p and -92b-3p) were consistently decreased with invasive progression. Exosome miRNA expression was confirmed in breast cancer cell lines and mouse plasma exosomes.

Conclusion: This work demonstrates that the microRNA contents of exosomes change upon malignant transformation to invasive breast cancer and indicate that certain exosome microRNAs are consistently up- or down-regulated and may contribute to breast cancer progression.
MicroRNA-137 inhibits cancer progression by targeting DEL-1 in triple negative breast cancer cells, MDA-MB-231

Yee Soo Chae¹, Dong Won Baek¹, In Hee Lee¹, Soo Jung Lee¹, Ryu Kyung Lee¹, Jiyeon Lee¹, Jinhyang Jung¹, Hoyong Park¹, Jae-Hwan Jeong¹, Jieun Kang¹ and Jiyoung Park¹. ¹Kyungpook National University School of Medicine, Daegu, Korea.

Background: This study aimed to investigate the function of microRNA-137 in Del-1 expression in triple negative breast cancer (TNBC) cells and tissues.

Methods: The Del-1 mRNA and microRNA levels were measured using a qRT-PCR in breast cancer cells (MDA-MB-231, MCF7, SK-BR3, and T-47D) and tissues from 20 patients with TNBC. The effects of miR-137 on cell proliferation, migration, and invasion were determined using MTT, wound healing, and Matrigel Transwell assays.

Results: microRNA-137 (miR-137) levels were remarkably low and Del-1 mRNA expression was higher in MDA-MB-231 cells as compared to other breast cancer cell lines. The luciferase reporter assay revealed that miR-137 binds directly at the 3¢-UTR of Del-1 and that Del-1 expression was downregulated by miR-137 mimics and rescued by its inhibitors. Furthermore, miR-137 inhibited the cell proliferation, migration, and invasion of MDA-MB-231 cells. Moreover, among the 30 TNBC specimens, miR-137 was downregulated (p < 0.0001) and the level of Del-1 in plasma was significantly elevated as compared to normal controls (p < 0.0001).

Conclusions: In conclusion, miR-137 regulates Del-1 expression in TNBC via directly binding to the Del-1 gene, and thereby affects cancer progression. This suggests that miR-137 may be a new therapeutic biomarker for patients with TNBC.

Keywords: Del-1, triple negative breast cancer, miR-137, biomarker
Mir-4319 suppresses the malignancy of triple-negative breast cancer by regulating self-renewal and tumorigenesis of stem cells

Jiahui Chu¹, Yongfei Li¹, Ziyi Fu¹, Jinhai Tang¹ and Yongmei Yin¹. ¹The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background/Aims High levels of cancer stem cells (CSCs) in patients with triple-negative breast cancer (TNBC) correlate with risk of poor clinical outcome and possibly contribute to chemoresistance and metastasis in patients with highly malignant TNBC. Aberrant microRNA expression is associated with the dysfunction of self-renewal and proliferation in cancer stem cells, while there is little information about the TNBC-specific microRNAs in regulating CSC ability.

Methods Solexa deep sequencing was performed to detect the expression levels of TNBC or non-TNBC stem cells (CSCs) microRNAs. Mammosphere formation assay, qRT-PCR and the xenograft model in nude mice were performed. Bioinformatic analysis and microarray were used to select the target gene, and luciferase reporter assays were used to confirm the binding sites.

Results Solexa sequencing data exhibited differential expression of 193 microRNAs between TNBC and non-TNBC stem cells. The gene ontology analysis and pathways analyses showed that genes were involved in the maintenance of stemness. Overexpression of miR-4319 could decrease the tumorsphere-forming efficiency in MDA-MB-231 CSCs and also inhibit tumor initiation and metastasis in vivo. Knockdown of mir-4319 showed the reverse. Overexpression of miR-4319 greatly reduced luciferase activity of E2F2 by almost 50% and when the mismatch mutation was introduced into the region, the inhibition of luciferase activity was almost abolished. Moreover, increased E2F2 could reverse the effect of mir-4319 on the self-renewal in TNBC CSCs.

Conclusions Mir-4319 suppresses the malignancy of TNBC by regulating self-renewal and tumorigenesis of stem cells and might be a remarkable prognostic factor or therapeutic target for patients with TNBC.
Analyzing the physical and functional protein interaction landscape of breast cancer

Minkyu Kim1, Kyumin Kim1, Beril Tutuncuoglu1, Margaret Soucheray1, Danielle Swaney1, Fan Zheng2, Jisoo Park2, Patrick O'Leary1, Jean-Philippe Coppé1, Laura van 't Veer1, Alan Ashworth1, Trey Ideker2 and Nevan Krogan1. 1University of California San Francisco, San Francisco, CA and 2University of California San Diego, San Diego, CA.

A key unanswered question in cancer genetics is how different mutations, dispersed across a multitude of genes, elicit similar pathology and patient outcomes. The answer may lie in understanding the molecular networks and protein complexes (i.e. signaling pathways, chromatin architecture, etc) in cancer and mapping mutated genes into the complexes and pathways in which they function. Determining how systematic interaction networks are wired in cancer cells and how different mutations perturb these networks will guide the search for new cancer genes and provide a platform for integrating patient data to make biological and clinical predictions more accurate. The goal of this study is to uncover the comprehensive protein-protein interaction networks and pathways in various breast cancer subtypes to better understand how mutated cancer genes and genomes hijack and re-wire pathways and complexes during the course of breast tumorigenesis.

Here we catalog protein-protein interactions for 40 genes recurrently mutated in breast cancer, using affinity purification and mass spectrometry. To identify co-associated proteins, cDNA clones expressing each protein were tagged with 3xFLAG at either N or C-terminus and introduced into MCF10A (non-tumorigenic “healthy” control), MCF7 (luminal A subtype), and MDA-MB-231 (claudin-low) cells using doxycycline-inducible lentiviral vectors. For proteins with prevalent pathogenic mutations (e.g. PIK3CA-H1047R, BRCA1-C61G), mutant cDNA clones were also analyzed in parallel. Our interaction network reveals subtype and mutation-specific protein-protein interactions, many of which are not previously reported. Given that genes encoding components of a protein complex or a biological pathway often share similar phenotype upon genetic perturbation, we genetically knocked out genes interacting with DNA damage response (DDR) proteins using CRISPR/Cas9, and found multiple novel interacting genes whose knockout results in significant PARPi (olaparib) and/or cisplatin sensitivity. This result not only functionally validates the physical protein interactions, but also demonstrates that our interactome mapping approach can help identify new druggable vulnerabilities in cancer cells.

We anticipate the breast cancer interactome study will uncover aberrant pathways and protein complexes uniquely operating in breast cancer cells, and thus pinpoint proteins that may potentially serve as distinct biomarkers or therapeutic targets for tumors having the same or similar subtypes and/or genomic mutations.
A translational and five-year clinical update in patients treated with neoadjuvant chemotherapy randomized to bevacizumab or control in HER2 negative breast cancer

Hedda von der Lippe Gythfeldt¹, Olav Engebråten¹, Bjørn Naume¹, Erik Wist¹, Elin Borgen¹, Tonje Lien², Ole Christian Lindgjærde², Øystein Garred¹, Ellen Schlichting¹, Laxmi Silwal-Pandit² and Anne Lise Borresen-Dale². ¹Oslo University Hospital, Oslo, Norway and ²OUS, Oslo, Norway.

**Background:** Bevacizumab added to conventional neoadjuvant chemotherapy increase the proportion of patients achieving a pathological complete response (pCR). Identifying patients responding to antiangiogenic therapy have been challenging. The primary objective of this study was to determine the molecular characteristics and treatment induced changes of the primary tumors with reference to treatment response. Clinical outcome measurements according to treatment were exploratory endpoints. Recent updated clinical results, in addition to extended molecular analyses are presented.

**Methods:** A phase II randomized clinical trial of HER2 negative primary tumors of $\geq 25$ mm ($n=132$) was conducted, treated with neoadjuvant chemotherapy (4xFEC100 followed by taxane-based therapy) with or without the addition of bevacizumab. Biopsies were obtained at the time of diagnosis, after 12 weeks of treatment, and after 25 weeks at surgery. The response was evaluated using the criteria for determining the residual cancer burden (RCB). We derived a mean immune score per patient by calculating the average score from the 770 genes in the nCounter PanCancer immune panel to detect an association between immune activity and response to antiangiogenic therapy. In addition, the median five-year follow-up for disease recurrence are reported.

**Results:** The addition of bevacizumab increased the RCB class 0 (pCR) rate in the study population from 12% to 17% and the rate of “good responders” (RCB class 0 and 1) from 24% to 33%, without reaching statistical significance. A pronounced effect of bevacizumab combination therapy was observed in the hormone receptor (HR) positive tumors, were the percentage of patients achieving RCB class 0 increased from 5% to 20% (Fisher’s Exact test, p=0.02). More HR positive patients achieved a good response and fewer patients were poor responders (RCB class 3) in the combination treatment arm (Wilcoxon, p=0.035).

Previously, our unsupervised analyses demonstrated an enrichment of immune related genes in pretreatment samples from patients responding to combination therapy. A significantly higher mean immune score (p<0.001) was detected among the HR positive patients who received bevacizumab and achieved RCB class 0 after neoadjuvant treatment ($n=11$, 20%). Five-year follow-up data revealed a total of 21 events in the study population; 9 relapses in patients treated with combination therapy, and 12 relapses in patients treated with chemotherapy only. DFS was not statistically different between the treatment groups (log rank, p=0.4257). However, among the patients achieving a good response an improved DFS was observed for those treated with combination therapy (1/22 vs. 5/16, log rank, p=0.0254).

**Conclusion:** Among locally advanced HER2-negative HR positive breast cancer patients, the addition of bevacizumab to neoadjuvant chemotherapy increased the rate of good responders and improved the DFS among these patients. An increased primary tumor immune score may predict good response to neoadjuvant antiangiogenic therapy in HR positive disease. Further studies are needed to validate the use of such immune panels for selection of patients most likely to benefit from antiangiogenic therapy.
The CARMA3-Bcl10-MALT1 signalosome mediates pro-angiogenic IL-6 and IL-8 paracrine signaling in GPCR+ breast cancer

Heejae Kang¹, Prasanna Ekambaram², Linda M McAllister-Lucas² and Peter C Lucas². ¹Medical Scientist Training Program, University of Pittsburgh School of Medicine, Pittsburgh, PA and ²University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background: The overexpression of selected G-protein coupled receptors (GPCRs) has been linked to the pathogenesis of multiple cancer subtypes. We recently demonstrated that overexpression of two such GPCRs, the angiotensin II receptor type I (AGTR1) and protease-activated receptor type 1 (PAR1), occurs in a substantial fraction of luminal breast cancers and is associated with treatment resistance and poor prognosis. Further, experimental models demonstrate that overexpression of these receptors in breast cancer cell lines promotes aggressive features that include EMT, invasion, migration, and loss of ER expression. In addition to these cell intrinsic effects, we find that GPCR overexpression in breast cancer cells can impact the tumor microenvironment. Specifically, we recently reported that conditioned media from angiotensin II-stimulated AGTR1+ breast cancer cells induces endothelial chemotaxis in vitro and tumor angiogenesis in vivo. We also demonstrated that this pro-angiogenic phenotype requires the CARMA3-Bcl10-MALT1 (CBM) signalosome, a signaling complex that links upstream GPCR stimulation with downstream NF-κB activation. We hypothesized that stimulation of either AGTR1 or PAR1 induces CBM-dependent secretion of NF-κB responsive, pro-angiogenic factors from these GPCR+ breast cancer cells which then exert proangiogenic effects on neighboring endothelial cells through paracrine signaling.

Methods: To identify CBM-dependent secreted factors, we evaluated the AGTR1+ BT549 cell line, +/- Bcl10 or MALT1 siRNA knockdown, for expression of 770 genes of significance to solid tumor pathogenesis using the NanoString PanCancer Progression Panel followed by Ingenuity Pathway Analysis (IPA). RT-PCR and ELISA were used to validate hits and determine if the CBM signalosome controls expression of the same genes in the PAR1+ cell lines, MCF7-N55 and MDA-MB-231.

Results: We identified IL-6 and IL-8 signaling pathways as the two most significantly downregulated angiogenesis pathways following either Bcl10 or MALT1 knockdown. Using quantitative RT-PCR and ELISA, we confirmed that IL-6 and IL-8 gene expression and protein secretion are significantly induced in response to stimulation of BT549 cells by angiotensin II and MCF7-N55 and MDA-MB-231 cells by TRAP6, a PAR1 agonist. siRNA-mediated MALT1 knockdown in BT549 cells led to a significant reduction of IL-6 and IL-8 gene expression upon angiotensin II stimulation; similarly, CRISPR/Cas9-mediated MALT1-deletion in MCF7-N55 cells resulted in failure of these cells to secrete IL-8 upon TRAP6 stimulation.

Conclusions: The GPCR-CBM-cytokine signaling pathway provides a common druggable target to curb pro-angiogenic paracrine signaling in GPCR+ breast cancers. Importantly, the CBM signalosome has also been shown to be required for IL-8 dependent upregulation of VEGF in endothelial cells, indicating that inhibition of the signalosome could exert complementary effects on both cancer cells and endothelial cells to effectively limit the pro-angiogenic phenotype driven by GPCR overexpression. Several small-molecule MALT1 inhibitors are now available and can be tested for their efficacy as angiogenesis inhibitors in the setting of GPCR+ breast cancer.
A live tissue platform allows dynamic measurement of neovascularization and prediction of clinical response in human breast cancer samples, *ex vivo*

Munisha Smalley¹, Neyaz Alam², Nabendu Murmu², SP Somashekhar³, Baraneedharan Ulaganathan¹, Allen Thayakumar¹, Laura Maciejko¹, Jyothsna Ganesh¹, Mark Lawson¹, Hans Gertje¹, Basavaraja U Shanthappa¹ and Aaron Goldman¹. ¹Mitra Biotech, Woburn, MA; ²Chittaranjan National Cancer Institute, Kolkata, West Bengal, India and ³Manipal Hospitals, Bengaluru, Karnataka, India.

Background: Outgrowth of new blood vessels (neovascularization) allows tumors to supply themselves with oxygen and nutrients, and to rapidly metastasize throughout the body. Triple negative breast cancer (TNBC) is particularly susceptible to neovascularization. However, success with anti-angiogenics is highly variable and often patient-specific. This is particularly true as anti-angiogenics are being combined with immunotherapies. Thus, there is a huge unmet need for clinicians to test and predict clinical efficacy of anti-angiogenics at the individual patient level, prior to treatment.

Methods: Here, we characterize a patient-autologous, *ex-vivo* tumor model, termed CANscript, as a platform to study the intratumor microvascular density (iMVD) of breast cancer samples (N=15). To profile iMVD we used immunohistochemical (IHC) analysis of CD34, an early biomarker of neovascularization. We then introduced anticancer and anti-angiogenic agents (e.g. Avastin) for 72 hours, and subsequently quantified phenotypic response to drugs by testing viability, cell death, proliferation and morphology. These quantitative data were then fed into a machine learning algorithm that provides a clinical response prediction (M-Score).

Results: We determined that *ex-vivo* culture reliably retains baseline heterogeneity of iMVD based on expression of CD34+ nodes per visual field by IHC. Furthermore, we show that anticancer and anti-angiogenic agents will dynamically alter iMVD, *ex-vivo*, in a patient-specific manner. Finally, we show that prediction of clinical response using the 'M-Score' algorithm associates with diminished expression of CD34 per visual field of IHC after drug pressure.

Summary: Neovascularization and iMVD are features of aggressive cancers, such as TNBC. CANscript provides a rapid assessment of clinical response to anticancer drugs, many of which induce their antitumor effect by targeting the tumor vasculature. We show that pharmacodynamics of antiangiogenics can be captured during acute *ex-vivo* culture under drug pressure, which associate to clinical response prediction. Therefore, we highlight the ability of CANscript as a platform to predict clinical response to anti-angiogenic drugs, and may therefore be a logical ‘testing ground’ to predict clinical efficacy of antiangiogenic drugs combined with immunotherapies.
Gene expression profiles of angiogenesis related cytokines and cognate receptors predict breast cancer progression and survival

James L Wittliff¹, Seth B Sereff¹, Irina A Smolenkova¹, Zohair R Hameed¹ and Sarah A Andres¹. ¹University of Louisville, Louisville, KY.

Background: Angiogenesis plays a critical role in breast cancer development, invasion and metastasis, and VEGF, TGFβ1, and IL10 genes and their cognate receptors are implicated in cancer behavior, mediating membrane and microenvironment remodeling. Our goal is to assess relationships of expression of these genes in LCM-procured carcinoma cells from primary breast cancers with clinical outcomes to predict risk of recurrence.

Methods: Gene expression determined by microarray and qPCR, ER/PR quantified by radio-ligand binding or EIA, features of primary breast cancers and clinical outcomes were performed by univariable and multivariable Cox regressions, Kaplan Meier plots and LASSO with R software v3.2.5. Microarray analyses of ~22,000 genes utilized RNA isolated, purified and amplified from LCM-procured carcinoma cells. Gene expression was validated by qPCR while molecular signatures were externally validated with SurvExpress (Aguirre-Gamboa et al. PLoS One e74250, 2013).

Results: Univariable Cox regression of microarray results of cytokines and cognate receptor genes revealed IL10 expression was significant for prediction of Progression Free (PFS) or Overall Survival (OS) using an adjusted p-value of ≥ 0.30 (discovery cut-off). Without regard to ER/PR status, Kaplan Meier plots confirmed IL10 or TGFβ1 expression was significant for predicting PFS and OS. Using ER+ cancers, IL10 or VEGF expression was related to PFS while only IL10R was related to OS of ER- cancers using univariable Cox regression. Validation by qPCR using tissue curls disclosed independent expression of either TGFβ1 or VEGF predicted PFS and OS while that of TGFβ1R was only related to PFS. IL10R expression only predicted OS of breast cancer patients. Violin plots of qPCR results indicated elevated expression of each of these six genes in ER+ primaries without regard to outcome. Multivariable Cox regression analyses of expression levels of cytokine-receptor gene pairs revealed that IL10-IL10R co-expression was highly significant for predicting OS. Strongly supportive, backwards selection (R software v3.2.5) utilizing microarray expression levels derived a significant model (molecular signature) consisting of IL10, IL10R and VEGFR genes for predicting OS. External validation of this 3-gene subset was accomplished utilizing patient data collected on SurvExpress. A second clinically relevant signature predicting OS in PR+ breast cancers was detected when TGFβ1R expression was included with these 3 genes. Finally, backwards selection of qPCR data derived a significant 3-gene model composed of IL10R, TGFβ1 and VEGF for predicting PFS that was undeniably validated by SurvExpress.

Conclusions: Using gene expression results derived from microarray analyses of LCM-procured breast carcinoma cells of primary lesions and validated by qPCR, subsets of angiogenesis related genes were identified that predict a patient's risk of recurrence and overall survival. Expression of candidate genes appears to be related to either/both ER or PR protein status of the primary lesion. Collectively, results suggest that expression of certain angiogenesis related genes may serve as biomarkers for assessing prognosis of breast carcinomas thus impacting clinical management.
Metformin modulates the senescence-associated secretory phenotype (SASP) in paclitaxel-resistance triple-negative breast cancer cell line

Isabella Guimarães, Etel Gimba, Morgana Castelo-Branco, Cinthya Sternberg, Ian Silva and Leticia Rangel.

1Biotechnology Program/RENORBIO, Federal University of Espirito Santo (UFES), Vitoria, Espirito Santo, Brazil; 2Brazilian National Cancer Institute (INCa), Rio de Janeiro, Brazil; 3Health and Humanities Institute, Fluminense Federal University, Rio das Ostras, Rio de Janeiro, Brazil; 4Molecular and Cellular Oncology Program, Research Coordination, INCa, Rio de Janeiro, Brazil; 5Anatomic Pathology Program, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; 6Brazilian Society of Clinical Oncolgy, São Paulo, Brazil; 7UFES, Vitoria, Espirito Santo, Brazil and 8Biochemistry and Pharmacology Program, UFES, Vitoria, Espirito Santo, Brazil.

Background: Breast cancer (BC) is a complex disease subdivided into distinct tumor types based on the expression of molecular markers, which might also guide the prediction of patient’s outcome and tumor response to therapy. Triple-negative breast cancer (TNBC) is an aggressive form of BC that frequently recurs and leads to cancer-related death. This is due, at least partially, to the absence of specific targets that can be used in the fight against TNBC, narrowing the disease care to conventional chemotherapy based on anthracyclines and taxanes. Chemosresistance is a major cause of tumor relapse, and because it is a multifactorial phenomena, it still challenges clinicians and investigators. Amongst the mechanisms involved in chemo/radio-resistance of tumor cells, there is the acquisition of a senescence-associated secretory phenotype (SASP). Metformin, a safe hypoglicemic drug, has been shown to act in synergy with certain anti-cancer agents, overcoming chemoresistance in various types of tumors. The present work aimed to investigate the use of metformin as a novel treatment strategy for paclitaxel-resistant BC.

Methods: MDA231-PR cell line was established from its parental cell MDA-MB-231, using a pulse-selection in clinics. The effects of metformin alone or in combination with conventional drugs on BC cell lines were investigated using the MTT assay for cellular metabolic viability (CMV). Gene and protein expression, as well as secreted proteins were determined in BC cells by real-time RT-PCR, Western blotting and ELISA assay, respectively. Flow cytometry analysis was applied for apoptosis analysis, and SA-β-Gal staining was used to investigate cellular senescence.

Findings: We characterize SASP in MDA231-PR. Moreover, several pathways related to the acquisition of chemoresistant phenotype by tumor cells were modified in MDA231-PR, including CSC and autophagy phenotypes, MAPK, mTOR and GSK-3β. Furthermore, we showed that metformin inhibits the expression of genes coding for multiple pro-inflammatory cytokines accompanying cellular senescence. Remarkably, metformin reversed the paclitaxel resistance in MDA-MB-231 in the presence of conditioned medium from MDA231-PR.

Conclusions: Altogether, our observations suggest that paclitaxel-treated TNBC cells induced SASP, contributing for senescence-related inflammation and stem cell dysfunction. Additionally, our findings support the fact that metformin is a potential agent against TNBC, which remains a major challenge for clinical oncology, especially in tumors refractory to taxanes.
In primary, non-metastatic breast cancer patients, increased serum levels of RANKL significantly correlate with tumor cell spread to the bone and the occurrence of bone metastasis whereas high levels of its soluble decoy receptor osteoprotegerin predict poor survival.

Ann-Kathrin Bittner¹, Andy Goebel², Oliver Hoffmann¹, Martina Rauner², Lorenz C Hofbauer², Rainer Kimmig¹, Sabine Kasimir-Bauer¹ and Tilman D Rachner². ¹University Hospital Essen, Essen, Germany and ²Division of Endocrinology, Diabetes, and Bone Diseases, Dresden, Germany.

**Background:** Receptor activator of nuclear factor kappa-B ligand (RANKL) is an essential protein for osteoclast regulation and its activity is controlled by its soluble decoy receptor osteoprotegerin (OPG). RANKL has been associated with benign as well as malignant bone disease and there is increasing evidence that RANKL may also directly affect breast cancer (BC) progression and metastasis to the bone. Here we assessed serum concentrations of RANKL and OPG in 509 patients with primary, non-metastatic BC and correlated the results with clinical parameters including the presence of disseminated tumor cells (DTCs) in the bone marrow (BM), survival and the risk of developing metastatic disease.

**Patients and Methods:** Patients with first diagnosis of BC between Aug 2006 and Dec 2009 were included in our study. BM sampling was performed before surgery in an adjuvant setting and two BM aspirates were analyzed for DTCs using density centrifugation followed by immunocytochemistry applying the pan-cytokeratin antibody A45-B/B3. Blood was collected from each patient and sRANKL and OPG levels in the serum were measured by ELISA (Biomedica, Vienna, Austria). **Results:** Mean serum values for RANKL and OPG were 0.23±0.20 pmol/l and 4.24±1.70 pmol/l, respectively. RANKL levels were significantly lower in women above the age of 60 (p<0.0001) and RANKL/OPG ratios were higher in patients with lymph node involvement (p<0.05). High OPG levels were associated with a higher risk of death from BC (HR 1.94 95%CI 1.23-3.07; p=0.005) and multivariate analyses revealed OPG to be an independent prognostic marker for BC specific survival (p=0.035). DTCs were detected in 207/507 (41%) patients and RANKL levels were 33% higher in DTC-positive patients (p=0.035). DTCs were detected in 207/507 (41%) patients and RANKL levels were 33% higher in DTC-positive patients (p=0.035). Interestingly, in DTC-negative patients, high RANKL levels were associated with a significantly better BC specific survival compared to low levels (HR 0.524; 95%CI 0.30-0.95; p=0.04). RANKL serum levels were significantly enhanced in patients that developed bone metastases (p=0.01) and patients in the highest quartile of RANKL had a significantly increased risk of developing bone metastases compared to those in the lowest RANKL quartile (HR 4.62, 95%CI 1.49-14.34, p=0.03). **Conclusion:** Increased OPG levels indicated poor survival and high RANKL significantly associated with an increased risk of developing bone metastases while indicating a positive prognostic marker in DTC-negative patients. These findings warrant further investigation as it may provide a rational for novel diagnostic or therapeutic approaches.
Effects of palbociclib on thymidine kinase-1 (TK1) in hormone receptor positive (HR+) breast cancer cell lines

Martina Bonechi, Ilenia Migliaccio, Matteo Benelli, Dario Romagnoli, Mattias Bergqvist, Karin Mattsson, Giulia Boccalini, Gloria Capaccioli, Francesca De Luca, Francesca Galardi, Chiara Biagioni, Emanuela Risi, Amelia McCartney, Lorenzo Rossi, C Kent Osborne, Rachel Schiff, Carmine De Angelis, Cristina Guarducci, Angelo Di Leo and Luca Malorni.

Introduction: TK1 plays a crucial role in DNA synthesis and is a well-established marker of cell proliferation. We and others have previously described the potential role of TK1 activity (TKa) as predictive biomarker of response to endocrine therapy in HR+/HER2 negative metastatic breast cancer patients. TK1 synthesis is regulated by the E2F pathway, the target pathway of CDK4/6 inhibitors, and TKa has recently been reported as a potential circulating pharmacodynamic marker of CDK4/6 inhibition in breast cancer. However, modulations of TK1 levels and activity during palbociclib treatment and in the development of treatment resistance are unknown. Here, we report how TK1 expression and TKa are modulated in response to palbociclib in a panel of HR+ breast cancer cell lines: both palbociclib-sensitive (PDS) and with acquired resistance to (PDR).

Material and methods: We used a panel of 7 PDR HR+ breast cancer models previously developed in our lab via chronic exposure of parental cells (MCF7, T47D, ZR75-1, BT474, MDA MB361 and two MCF7 endocrine resistant derivatives) to escalating doses of palbociclib, from a Starting Treatment Concentration (STC) of 50 nM or 350 nM according to the cell line, up to 1 µM. We analyzed gene expression profiles of PDS cells treated with drug vehicle (DMSO) as a control or palbociclib at STC for 3 days, and PDR cells grown with palbociclib 1 µM. Cell proliferation was assessed by methylene blue assay in MCF7 and BT474 PDS and PDR treated for 3, 6 and 9 days with DMSO, palbociclib STC and 1 µM. In parallel, TKa was measured in cell lysates at 3 days of treatment using the DiviTum™ assay (Biovica, Sweden).

Results: Among E2F target genes, gene expression data demonstrated that TK1 was one of the most differentially expressed genes between PDR and PDS treated cells. In PDS cells compared to control, treatment with palbociclib resulted in reduced TK1 expression, with the HER2 positive models (BT474 and MDA MB361) showing the highest reduction. In PDR cells, TK1 expression was higher, but remained slightly inhibited compared to untreated PDS cells. TKa was significantly reduced in PDS cells treated with palbociclib for 3 days compared to vehicle (p<0.05). TKa response to palbociclib was more dramatic in BT474 cells as compared to MCF7. As expected, palbociclib inhibited cell proliferation in PDS models, with a significant reduction observed only after 6 days of treatment, suggesting that TKa may be an early marker of growth inhibition in response to palbociclib. No significant alterations in TKa were observed in PDR cells, at any dose of palbociclib. Similarly, proliferation rate was not affected by palbociclib in PDR cells.

Conclusions: TK1 expression and activity are regulated by palbociclib in HR+ breast cancer cell lines, particularly in HER2 positive models. Ongoing studies of TKa in patients treated with palbociclib will assess the role of TKa as a circulating biomarker for predicting and monitoring response to CDK4/6 inhibitors.
Association of Caspase 8 polymorphisms with TILs and disease-free survival in primary breast cancer patients

Pauline Wimberger¹, Hagen Sjard Bachmann², Jan Dominik Kuhlmann¹, Theresa Link¹, Eric Kröber³, Christoph Thomssen³, Brahima Malle³, Martina Vetter³ and Eva Johanna Kantelhardt³. ¹Techinische Universität Dresden, Dresden, Germany; ²Centre for Biomedical Education and Research (ZBAF), Witten/Herdecke University, Witten, Witten, Germany and ³Institute of Pathology, Martin-Luther-University Halle-Wittenberg, Halle, Germany.

BACKGROUND: The minor allele of two caspase-8 polymorphisms, namely CASP8 -652 6N InsDel and CASP8 Asp302His, were shown to promote survival of T-lymphocytes and were repeatedly associated with reduced breast cancer susceptibility. However, besides some preliminary findings, clinical relevance of these polymorphisms in patients with already existing primary breast cancer has not yet been established. Considering an immunomodulatory and potentially tumor-protective role of these caspase-8 variants, we genotyped 785 primary breast cancer patients and correlated caspase-8 variants with i) disease-free survival (DFS) and ii) the presence of tumor infiltrating lymphocytes (TILs).

METHODS: Primary breast cancer samples were collected at the Martin-Luther University, Halle-Wittenberg between 2009 and 2011 as part of the multicenter prospective PiA trial (NCT 01592825). The majority of patients had luminal-like tumors (75.9%), followed by triple negative (10.1%), luminal-Her2-like (9.6%) and Her2-enriched tumors (4.5%). Genotyping was performed by pyrosequencing, TILs status was assessed by hematoxylin and eosin staining.

RESULTS: The CASP8 -652 deletion was significantly associated with improved DFS in an allele-dose dependent manner (p=0.027). Homozygosity for the -652 6N Del variant was an independent predictor for improved DFS (p=0.005). In patients with a 302His/His genotype, there was no event of recurrence during the entire observation time. Combined analysis of diplotypes revealed that both polymorphisms had an influence on DFS (p=0.029). Interestingly, patients with the 302His/His variant among the unstratified patient cohort and among the luminal-like subtype alone had tumors with very low lymphocyte infiltration (0-10% TILs in 65% of cases compared to 31% of cases for other genotypes, p=0.025).

CONCLUSION: In line with previous epidemiological findings, we propose a prognostically favorable role of the CASP8 -652 6N Del and the Asp302His variant in primary breast cancer patients. Moreover, we suggest for the first time a role of the Asp302His variant in immunosurveillance and lymphocyte infiltration of breast cancer. Our findings strongly encourage further analyze of these genetic variants as a biomarker for prognostic and immunotherapeutic considerations.
Predictive factors for considering to avoid axillar lymphadenectomy in selected node positive breast cancer patients after neoadjuvant chemotherapy

Sergi Fernandez-Gonzalez¹, Catalina Falo Zamora², Diana Nuñez¹, Andrea Vethencourt², Maria Jesus Pla¹, Teresa Soler¹, Anna Guma², Xavier Perez², Miguel Gil², Jordi Ponce¹ and Amparo Garcia¹. ¹Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain and ²Institut Català d'Oncologia, L'Hospitalet de Llobregat, Barcelona, Spain.

Background:
To perform a systematic axillar lymphadenectomy (ALND) in clinical node positive (N+) patients after neoadjuvant chemotherapy (NACT) is currently under discussion. We aimed to study which factors are related to a pathological complete axillary response (ypN0) after NACT in order to select which patients could benefit from a sentinel lymph node biopsy without interfering with survival.

Material and methods
N+ patients who underwent ALND after NACT between June 2008 and December 2016 were retrospectively analyzed. Clinical features, molecular and histological factors, recurrence and specific mortality rates were compared between patients achieving a complete pathological axillary response vs not (ypN0 vs ypN+).

Results
345 N+ patients were reviewed. After NACT, 137 (39.6%) become ypN0, 9 (2.6%) ypN1 mic, 113 (32.7%) ypN1, 60 (17.3%) ypN2 and 22 (6.4%) N3. Univariate analysis results regarding the predictive factors for ypN0 are detailed in [table 1].

Multivariate analyses showed molecular subtype (TN and Her2+) and clinical response as independent predictors of ypN0 [table 2].

Table 2. Multivariate analysis logistic regression of clinical predictive factors of ypN0.

OR: Odd ratio. No-luminal includes: luminal B (HER2 +), HER2 Henriched and triple negative. Luminal includes: Luminal A and Luminal B (HER2 -).

After a mean follow-up of 58 months, overall survival was statistically superior in ypN0 vs ypN1 (p= 0.001).

Conclusions
A remarkable percentage of N+ became ypN0 after NATC. Molecular subtype and complete clinical response were independent predictive factors of ypN0. We propose to offer the benefit of a targeted axillary procedure in those patients.
Optical Prediction of Time Interval to Metastasis (OPTIM): A rapid nondestructive optical assay applied to tissue microarray samples identifying high risk of distant recurrence in the lowest risk groups defined by the TAILORx trial

Robert L Hill¹, Seth W Perry¹, Peter Salzman¹, Bradley M Turner², David G Hicks² and Edward B Brown³. ¹Harmonigenic Corporation, Rochester, NY; ²University of Rochester Medical Center, Rochester, NY and ³University of Rochester, Rochester, NY.

Recent reporting of the 9 year follow-up for the TAILORx trial suggests that there may be no benefit with adjuvant chemotherapy for ER +, HER2 -, N(0) breast cancer patients with a Oncotype DX® (ODX) recurrence score (RS) <26. Since endocrine therapy for this group of patients who comply with treatment still results in distant recurrence (rMBC) in 3% and 5% of the ODX low and ODX intermediate risk groups at 9 years, respectively, we are motivated to help find early treatments for these patients by identifying their recurrence risk at diagnosis with improved risk stratification.

Methods: Optical Prediction of Time Interval to Metastasis (OPTIM), a novel assay, prognostic for rMBC, is based on an intrinsic optical signature from collagen, derived from the average of point by point ratios of forward to backward (F/B) second harmonic generation (SHG) light scatter that is sensitive to form and structure of fibrillar collagen in the extracellular matrix of archival tissue microarray samples. (Burke et al. BMC Cancer 15 (2015): 929). The 125 patients in this cohort were part of a clinical trial, looking for genomic predictors of rMBC in untreated patients, so we were able to calculate a surrogate 21-gene RT-PCR assay (S-ODX) value based on gene expression data available through NCBI GEO database (Gyorffy et al. Breast Cancer Res Treat (2012) 132:1025). We analyzed these patient's rMBC outcomes using logistic regression and Kaplan-Meier (KM) analysis.

Results: OPTIM alone stratified at 2.5X relative risk (RR) between quartiles Q1 and Q4, similar to S-ODX low vs high recurrence score (RS) groups (from TAILORx Trial) with 2.8X RR. Using quartiles of OPTIM vs S-ODX together we stratify patients to recurrence risk (rMBC/at Risk), with an improved risk stratification of 5X RR in the RS<26 low risk groups.

Combining S-ODX with OPTIM, low (L) or high (H) risk by assay, shows that they are independent and complementary. Notably 68%=85/125 are classified L by S-ODX (RS<26) and OPTIM effectively reclassifies H and L, and when combined with S-ODX H identifies 92%=45/49 of all rMBC at 10 years without treatment. Risk stratification improves to 6.8X RR comparing highest risk HH 66.7%=12/18 to lowest risk LL 9.8%=4/41.

Distant Recurrence Identified by High Risk Group of Each Assay

Conclusion: OPTIM as an independent prognostic optical bio-marker from collagen in intact tissue. Combination of OPTIM with the Oncotype DX® assay may produce a continuous risk estimator with higher dynamic range than either assay alone and will be the focus of future study, especially in a treated population, to determine if OPTIM might also predict response to treatment.
BRCAness as a prognostic marker in triple-negative breast cancer patients treated with neoadjuvant chemotherapy: A multicenter retrospective study
