Background: Triple negative breast cancer (TNBC) has several subtypes. Identification of markers associated with recurrence and poor prognosis in TNBC patients is critically needed. BRCAness is a set of traits in which BRCA1 dysfunction, arising from gene mutation, methylation or deletion, results in DNA repair deficiency. In the present study we evaluated the clinical significance and prognosis of BRCAness in a multicenter retrospective study.

Methods: Ninety-four TNBC patients treated with neoadjuvant chemotherapy (NAC) were enrolled from three hospitals in Japan for this retrospective study. Of these patients, 86 (91.5%) were treated with anthracyclines and taxanes. BRCAness was determined from 94 core needle biopsy (CNB) specimens prior to NAC and 50 surgical specimens without pathological complete response (pCR). The samples were assessed using multiplex ligation-dependent probe amplification (MLPA) and the amplicons were scored. Samples with scores >0.5 were defined as having BRCAness.

Results: Of the 94 TNBC patients, 51 (54.3%) had BRCAness in CNB specimens. There were no significant differences in pCR rate or recurrence between the BRCAness and non-BRCAness groups. Among surgical specimens, the BRCAness group (19/50, 38%) had a significantly shorter recurrence-free survival (RFS) and disease-specific survival (DSS) compared with the non-BRCAness group (p < 0.01 and p < 0.05). The BRCAness group had independent prognostic factors for recurrence and survival in multivariate regression analysis.

Conclusions: The BRCAness of surgical specimens is a useful marker to predict prognosis in TNBC patients after NAC. A clinical trial to assess the clinical impact of platinum-containing drugs with BRCAness is planned.
Expression of miR-106b in circulating tumor cells is associated with EMT and prognosis in metastatic breast cancer patients

Weige Tan², Gehao Liang¹, Xinhua Xie³, Luyuan Tan¹, Andrew J Sanders⁴, Zihao Liu¹, Yun Ling¹, Wenjing Zhong¹, Wen G Jiang⁴ and Chang Gong¹,⁴.¹Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation and Breast Tumor Center, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong Province, China; ²The First Affiliated Hospital of Guangzhou Medical University, Guangzhou Medical University, Guangzhou, Guangdong Province, China; ³Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine; Sun Yat-Sen University, Guangzhou, Guangdong Province, China and ⁴Cardiff China Medical Research Collaborative, Cardiff University School of Medicine, Cardiff University, Cardiff, United Kingdom.

Abstract

**Background:** Circulating tumor cells (CTCs) display changes in epithelial-mesenchymal transition (EMT) markers and miRNAs regulate EMT in breast cancer cells. The association between EMT characteristics and miRNA expression in CTCs of metastatic breast cancer (MBC) patients and their clinical implications remain unknown.

**Methods:** CTC-specific miRNAs were screened based on comparison of the miRNA profile between CTC and primary tumor. RT-PCR was used to quantify the expression levels of EMT makers and miRNA candidates. We enrolled 219 MBC patients with CTCs ≥ 5/7.5mL blood from 2 cohorts and CTCs were detected and enriched by CellSearch. Overall survival (OS) and radiological response were analyzed. CTCs were divided into epithelial- (E-CTCs) and mesenchymal-like CTC (M-CTCs) phenotypes based on a cut-off value derived from suspended breast cancer cells recovered from PBMCs.

**Results:** MiR-106b displayed upregulation in CTCs, with a higher level in M-CTCs than E-CTCs. Patients with E-CTCs showed better OS than those with M-CTCs (HR 1.77, 95% CI 1.14-2.78, \(P = 0.012\)). CTCs from chemo-resistant MBC patients exhibited higher miR-106b. CTC-specific miR-106b was negatively associated with therapy response and OS (HR 1.73, 95% CI 1.06-2.84, \(P = 0.029\)).

**Conclusions:** CTC-specific miR-106b was associated with EMT phenotypes of CTCs and may predict prognosis in MBC patients.
High circulating levels of Periostin are associated with a poor survival in primary, non-metastatic breast cancer patients

Oliver Hoffmann¹, Andy Goebel², Ann-Kathrin Bittner¹, Martina Rauner², Lorenz C Hofbauer², Rainer Kimmig¹, Sabine Kasimir-Bauer¹ and Tilman D Rachner². ¹University Hospital Essen, Essen, Germany and ²Dresden Technical University Medical Center, Dresden, Germany.

**Background:** Periostin, also known as osteoblast-specific factor OSF-2, functions as a ligand for integrins to support adhesion and migration of tumor cells which leads to increased cell survival, invasion, angiogenesis and metastasis in different cancer types including breast cancer (BC). Assuming that metastasis requires a dissemination of tumor cells, associated with worse outcome in BC, the aim of this study was to determine the expression of Periostin in blood samples of patients with primary, non-metastatic BC and to correlate the results with clinical parameters including the presence of disseminated tumor cells (DTCs) in the bone marrow (BM), survival and the risk of developing metastatic disease.

**Patients and Methods:** BM and blood sampling were performed before surgery in an adjuvant setting in 509 patients with first diagnosis of BC between Aug 2006 and Dec 2009. Two BM aspirates were analyzed for DTCs using density centrifugation followed by immunocytochemistry applying the pan-cytokeratin antibody A45-B/B3. Blood was collected from each patient and Periostin serum levels were measured by ELISA (Biomedica, Vienna, Austria).

**Results:** Periostin levels were detectable (504.8 ± 178.7 pmol/l) in all BC patients. There were no significant differences between serum Periostin levels when stratifying according to tumor stage, lymph node involvement or grading. Periostin levels were significantly increased in women above the age of 60 (468.6±166.6 pmol/l vs. 540.1±184.2 pmol/l; p<0.0001) and significantly enhanced in postmenopausal compared to peri- or premenopausal women (p<0.05 and p<0.001, respectively). No differences were observed between DTC-positive and DTC-negative patients. When separating patients according to high (top 50%) or low (low 50%) Periostin levels, patients with low Periostin levels had a significantly shorter BC specific survival (HR 0.61; 95%CI 0.39-0.96; p=0.03).

**Conclusion:** In summary, while Periostin levels were unchanged in patients with and without DTCs, high levels of Periostin were associated with a poorer BC specific survival. These results warrant further studies on the role of Periostin in BC.
Analysis of serial circulating tumor cell count during neoadjuvant systemic therapy in breast cancer patients

Sung-Chan Gwark¹, Jisun Kim¹, Young Hun Kim², Myoung Shin Kim², Ji Yeon Park¹, Sae Byul Lee¹, Guiyun Sohn¹, Il Yong Chung¹, Beom Seok Ko¹, Hee Jeong Kim¹, Jong Won Lee¹, Byung Ho Son¹ and Sei Hyun Ahn¹. ¹Asan Medical Center, Seoul, Republic of Korea and ²Cytogen Inc., Seoul, Republic of Korea.

Background: We aimed to evaluate the clinical implication of circulating tumor cell (CTC) counts in correlation with prognosis and radiologic/pathologic response to therapy in locally advanced breast cancer patients undergoing preoperative systemic therapy.

Methods: From Feb 2014 to May 2017, 207 patients without distant metastasis were prospectively enrolled from AMC. CTC counts were analyzed before-during-after the therapy. CTC isolation was performed using a SMART BIOPSY™ SYSTEM Isolation kit (Cytogen, Inc., Seoul, Korea). Recurrence-free and overall survival was analyzed according to CTC counts.

Result: The mean follow-up period was 22.46 months and mean age was 46.48 years. One or more CTC was identified in 132 of 203 patients (65.0%) before NST, in 135 of 186 patients (72.0%) during NST and 103 of 171 patients (60.2%) after NST. Initial tumor burden at diagnosis -tumor size, lymph node metastasis- was not correlated with CTC positivity. Overall, CTC count (≥1 CTC, ≥2 CTCs, and ≥5 CTCs) was not correlated with response to therapy. Using RECIST criteria, 86.5% (179/204) were responders (complete, partial response, CR/PR) and 12.1% (25/204) were non-responders (stable, progressive disease, SD/PD). 14.5% (30/207) showed a pathologic complete response (pCR), yet no association was found between CTC count/changes and radiologic/pathologic response to therapy. Also, CTC count was not correlated with prognosis among the whole population. However, HR+ tumors, CTC detection before NST was significantly associated with treatment response by RECIST criteria (responder vs. non-responder) (p=0.003, p=0.017 and p=0.023, respectively).

Conclusions: Our findings support limited value of CTC count for locally advanced breast cancers undergoing neoadjuvant systemic therapy.
Association of dermal lymphatic involvement and survival in inflammatory breast cancer

Kelly A Hirko¹, Julia Schlossman², Beth T Harrison³, Eren D Yeh⁴, Heather A Jacene⁵, Faina Nakhlis⁶, Emily Schlosnagle⁷ and Beth A Overmoyer². ¹College of Human Medicine, Michigan State University, East Lansing, MI; ²Susan F. Smith Center for Women's Cancers, Dana-Farber Cancer Institute, Boston, MA, Uganda and ³Brigham and Women's Hospital, Boston, MA.

Purpose: The pathologic hallmark of inflammatory breast cancer (IBC) is the presence of tumor emboli within the papillary and reticular dermis of the skin, termed dermal lymphatic invasion (DLI). DLI can be confirmed with a skin-punch biopsy in approximately 75% of cases, but its presence is not required for the diagnosis of IBC because of variability of tumor emboli in affected areas. The impact of confirming DLI by skin biopsy on the clinical outcome of IBC is unknown. We hypothesize that the ability to confirm DLI by biopsy is associated with a higher tumor emboli load and consequently a poorer disease prognosis. Therefore, we examined whether documented DLI was associated with poorer overall survival (OS) in IBC.

Methods: Clinical characteristics were evaluated among 286 women presenting with IBC between 1999 and 2016 and enrolled in the IRB-approved IBC registry at Dana-Farber Cancer Institute. Kaplan-Meier curves were used to estimate overall survival and the log-rank test to examine survival differences based upon the presence of DLI. Multivariable Cox proportional hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals for associations of DLI and risk of death among women with IBC.

Results: A total of 102 deaths occurred in our study population over a median follow-up of 2.5 years (yr) (range 10 days to 16 yr). Compared to IBC without DLI, IBC with confirmed DLI was more likely to be associated with the presence of lymphovascular invasion in breast biopsies (73.1% vs. 37.7%; p-value <0.01) but less likely to be seen with edema of the skin (59.1% vs. 81.1%; p-value=0.02). Documented DLI was not related to the presence of de novo metastasis at presentation (11.5% vs. 28.7%; p-value=0.07). OS did not significantly differ among women with IBC based upon the presence of DLI (log-rank test p-value=0.68). In multivariable models, DLI was not independently associated with OS in inflammatory breast cancer, HR(95%CI) = 0.92(0.48-1.78).

Conclusions: Our findings suggest that IBC presenting with documented DLI on skin biopsy may vary with regard to clinical characteristics at diagnosis, including lymphovascular invasion within the breast, edema of the skin of the breast, and the presence of de novo metastases. These clinical distinctions suggest potential differences in biology of IBC according to the presence or absence of DLI, and the extent of tumor emboli. However, in this study, DLI was not found to be an independent prognostic factor in IBC with respect to OS. Due to the variability in the clinical features of IBC at presentation and inherent complexities in selecting skin biopsy sites, studies to investigate the accuracy of determining DLI based on punch biopsy are necessary to more comprehensively assess the impact of DLI on clinical outcomes in IBC.
NFATC2 suppresses the metastatic cascade in breast cancer patients

Jingyan Xue¹², Yayun Chi¹², Jiajian Chen¹² and Jiong Wu¹². ¹Fudan University Shanghai Cancer Center, Shanghai, China and ²Shanghai Medical College, Fudan University, Shanghai, China.

For the patients with breast cancer, the pathological status of axillary lymph nodes is one of the most important predictor of prognosis. In recent years, the application of sentinel lymph node biopsy has provided us with an opportunity for the further study on the mechanism of lymph node metastasis in breast cancer. Through detailed pathological examination of sentinel lymph nodes, we can easily find patients who are in the early stage of lymph node metastasis - that is, the tumor cells from the primary tumor, invading the lymph nodes and successfully colonized, but not yet break through the lymph node microenvironment defense to the subsequent lymph node. It is the most important stage during lymph node metastasis.

In the present study, we selected the pairing samples from breast cancer patients with early stage lymph node metastasis to carry out differential genomics research. A total of 182 genes with significant function and involved in significant signal transduction pathways were obtained. Bioinformatics method was used to screen out the mRNA, microRNA and transcription factor in the process of lymph node metastasis of breast cancer. We investigated the role of activated T cells c2 (NFATC2) in the core transcription factors as a target for further clinical and basic research.

The expression of NFATC2 was detected in the tissue microarray prepared from 200 patients with primary breast cancer. After the median follow-up period of 89.5 months, it showed that the prognosis of patients with NFATC2 overexpression was significantly better than that of the control group (p = 0.022). We also measured the expression of NFATC2 in 50 pairs of breast cancer patients with lymph node metastasis. The results showed that the expression of NFATC2 in the primary tumor was significantly higher than that in the matched lymph node, suggesting that in patients with breast cancer, the down-regulate or deficiency of NFATC2 expression may be related with lymph node metastasis. We also attempted to add the expression of NFATC2 as a new parameter in the prediction model of lymph node metastasis based on preoperative clinical and pathological parameters. The area under the ROC curve obtained in the newly established model was 0.767, the expression state of NFATC2 had impact on the performance of the prediction model. Furthermore, when we removed the NFATC2 parameter, it could reduce the area under the ROC curve in the validation group, suggesting that the expression of NFATC2 in the primary tumor may be used as a predictor of the pathological state of axillary lymph nodes.

In vitro and in vivo experiments, we demonstrated that NFATC2 has a significant suppression effect on the proliferation, migration and invasion of breast cancer cells. The potential NFATC2-target genes were determined by RNAseq and Chipseq. Nine differentially expressed genes were found to be regulated by NFATC2 in the Chip-seq analysis and bound to the promoter region of the gene, whereas GRAMD3 and SRGAP2 in the subsequent validation showed a positive correlation with the expression of NFATC2, suggesting that the two genes are likely to have a positive regulatory relationship with NFATC2.

This study clarifies that NFATC2 may represent a therapeutic target for early metastasis breast cancer.
Using multiphoton laser scanning microscopy to assess neoadjuvant therapy outcome in core needle biopsies: A novel methodology

Danielle E Desa¹, Bradley M Turner², Brandon Buscaglia³, Robert L Hill⁴, Robert L Strawderman², David G Hicks² and Edward B Brown¹. ¹University of Rochester, Rochester, NY; ²University of Rochester Medical Center, Rochester, NY; ³Rochester Institute of Technology, Rochester, NY and ⁴Harmonigenic Corporation, Rochester, NY.

Background: Over-expression of Human Epidermal Growth Factor receptor-2 (HER2) in breast cancer is associated with an aggressive clinical course and poor prognosis. Targeting HER2 over-expression has been shown to be a remarkably effective therapeutic modality in the metastatic, adjuvant and neoadjuvant setting and the pathologic response to neoadjuvant treatment in HER2-positive breast cancer has been shown to be an excellent surrogate for a good outcome. The stromal tumor microenvironment is implicated in fostering tumor growth, facilitating cell migration and ultimately resulting in metastatic disease. Specifically, the collagenous extracellular matrix, which includes fibrillar collagen, has been suggested to play a role in the migration of malignant breast epithelial cells within the surrounding stroma. We have developed a novel methodology which uses an intrinsic optical signature to quantitatively evaluate fibrillar collagen (Burke et al. BMC Cancer 15 (2015): 929). Here, we evaluate the ability of this quantitative methodology to predict the pathologic response after neoadjuvant HER2-targeted treatment as assessed by the Residual Cancer Burden score/class (RCB). This quantitative evaluation in pre-treatment biopsies is then correlated with the pathologic response to treatment in the post-therapy resection. Material and Methods: Clinical pathologic variables for 29 cases of HER2-positive breast cancer that had undergone neoadjuvant chemotherapy plus HER2-targeted therapy were retrieved from the medical record database at URMC, including the post-treatment RCB score and ER/PR/HER2 status. Second harmonic generation (SHG) is an intrinsic optical signal produced by fibrillar collagen. To quantify collagen microstructure in the pre-treatment core biopsy, we used SHG imaging to determine the average forward to backward-light scattering ratio (F/B). The F/B ratio is sensitive to structural properties of collagen fibers. Results: Logistic regression was used to assess the association between F/B and the binary response variable RCB class (0/1 or 2/3). A likelihood ratio test was used to calculate the p-value to test whether the regression coefficient for F/B was zero (i.e. no effect) in the tumor-stromal interface. The average F/B ratio at the leading edge of the tumor stratified by RCB class is shown in Table 1. When evaluated in the bulk of the tumor tissue, F/B was not correlated with RCB status; however, when evaluated at the leading edge of the tumor-stroma interface, F/B was significantly correlated with RCB status (p=0.035).

Table 1: RCB class and average F/B

<table>
<thead>
<tr>
<th>RCB class (n)</th>

</tr>
</tbody>
</table>

Conclusions: We have previously shown that the measurement of F/B in the primary tumor after resection is an independent prognostic indicator of metastasis-free survival in breast cancer. Our results in the current study furthers these observations and suggests that the evaluations of the microstructure of collagen fibers by F/B measurement from the pre-treatment biopsy, specifically at the leading edge of the tumor-stroma interface, may be useful for predicting pathologic response to trastuzumab-based neoadjuvant therapy. Further studies in a larger patient cohort are warranted.
Consumption of sugar-containing beverages and cancer risk: Results from the NutriNet-Santé prospective cohort

Eloi Chazelas¹, Bernard Srour¹, Elisa Desmetz¹, Emmanuelle Kesse-Guyot¹, Chantal Julia¹², Nathalie Druesne-Pecollo¹, Pilar Galan¹, Laurent Zelek¹², Serge Hercberg¹², Paule Latino-Martel¹, Mélanie Deschasaux¹ and Mathilde Touvier¹. ¹Epidemiology and Statistics Research Center (CRESS), Inserm U1153, Inra U1125, Cnam, Paris 13 University, Nutritional Epidemiology Research Team (EREN), Bobigny, France and ²Avicenne Hospital, AP-HP, Bobigny, France.

OBJECTIVE
To assess the associations between the consumption of sugar-containing and artificially sweetened beverages and cancer risk.

DESIGN
Population based prospective cohort study.

SETTING AND PARTICIPANTS
Overall, 101,257 participants aged ≥18y (mean age: 42.2±14.4y) from the French NutriNet-Santé cohort (2009-2017) were included. Consumptions of sugar-containing and artificially sweetened beverages were assessed using repeated 24h-dietary records, designed to register participants' usual consumption for 3300 different food and beverage items.

MAIN OUTCOME MEASURES
Associations between beverage consumption and overall, breast, prostate and colorectal cancer risk were assessed by multivariable Cox Proportional Hazard models adjusted for known risk factors.

RESULTS
A 100mL increase in the consumption of sugar-containing beverages was significantly associated with an increased risk of overall cancer (HR=1.08, 95% confidence interval 1.04 to 1.12, P<.0001) and breast cancer (HR=1.11, 95% confidence interval 1.04 to 1.19, P<0.002). The consumption of artificially sweetened beverages was not associated with cancer risk. In sub-analyses, a 100 mL increase in the consumption of 100% fruit juice was significantly associated with an increased risk of overall cancers (HR=1.08, 95% confidence interval 1.02 to 1.15, P=0.01). These associations were strongly mediated by the sugar contained in these beverages. In contrast, weight gain during follow-up did not appear as a strong mediator. Besides, results were similar in overweight and non-overweight participants.

CONCLUSIONS
In this large prospective study, a 100mL increase in the consumption of sugar-containing beverages in the diet was associated with an 8% significant increase in overall cancer risk and an 11% significant increase in breast cancer risk. 100% fruit juices were also associated with an 8% increased risk of overall cancers. Given the massive consumption of sugar-containing beverages in Western countries, these results suggest that they may represent a key modifiable risk factor for cancer prevention.
Supplemental vitamin D intake amount needed to reduce breast cancer risk

Sharon L McDonnell¹, Carole A Baggerly¹, Christine B French¹, Leo L Baggerly¹, Cedric F Garland², Edward D Gorham² and Joan M Lappe³. ¹GrassrootsHealth, Encinitas, CA; ²University of California San Diego, San Diego, CA and ³Creighton University, Omaha, NE.

Background: Numerous studies have linked higher serum 25-hydroxyvitamin D [25(OH)D] concentrations to a lower risk of breast cancer. A recent study by McDonnell et al., which used data pooled from two randomized clinical trials (N=1129, N=2196) and a prospective cohort (N=1713), found that among women aged 55 years and older, those with 25(OH)D concentrations ≥60 ng/ml had an 80% lower risk of breast cancer than those with concentrations <20 ng/ml (HR=0.20, P=0.03), adjusting for breast cancer risk factors such as age, BMI, smoking status, and calcium supplement intake. Supplemental vitamin D intake is needed for most women today to achieve 60 ng/ml; however, the intake amount is unclear.

Objective and Methods: The objective of this analysis was to estimate the dose-response relationship between supplemental intake of vitamin D and serum 25(OH)D concentration using the pooled data from the McDonnell et al. study (N=5038) in order to provide guidance about dosing requirements to achieve 60 ng/ml. Women in the RCT cohorts participated in a four year, placebo-controlled, population-based trial of vitamin D and calcium supplementation in Nebraska. Vitamin D supplement intake was assessed by bottle weight for study provided supplements and by self-report for non-study vitamin D. Serum 25(OH)D concentrations were measured using radioimmunoassay. Women in the prospective cohort voluntarily participated in a longitudinal study and resided in 57 countries worldwide (91% in the United States or Canada). Supplemental vitamin D intake was assessed by self-report and serum 25(OH)D concentrations were determined by analysis of dried blood spot test kits using liquid chromatography-mass spectroscopy (LC-MS/MS). The relationship between supplemental vitamin D intake and 25(OH)D concentration was fitted to the following equation: \( Y = Y_0 + a(1-e^{bx}) + cX \), where \( X \) is daily supplemental vitamin D intake and \( Y \) is serum 25(OH)D concentration. This equation includes terms for the zero supplement intake value, hepatic 25-hydroxylation saturation, and zero-order kinetics for 25-hydroxylase.

Results: On average, a supplemental dose of 6,400 IU/day of vitamin D produced a 25(OH)D concentration of 60 ng/ml in this population of mostly white women aged 55 years and older. The dose required to ensure that 90% of this population achieved a 25(OH)D concentration of at least 60 ng/ml was approximately 13,000 IU/day. Concentrations above 100 ng/ml were observed in <0.2% of those taking 6,400 IU/day or less and <0.5% of those taking 13,000 IU/day or less. There was a significant amount of inter-individual variability in the response to any given dose. Therefore, serum 25(OH)D testing is recommended to determine the specific intake amount an individual needs to attain a specific 25(OH)D concentration.

Conclusion: To reduce breast cancer risk, the dosing recommendation for the general population of women is 6,400 IU/day with personalized dosing adjustments based on serum 25(OH)D testing.
Field testing of a point-of-care decision support tool for contralateral prophylactic mastectomy

Abenaa M Brewster¹, Scott Cantor¹, Kalatu Davies², Isabelle Bedrosian¹, Patricia Parker³, Siedah Garrison¹ and Robert J Volk¹. ¹MD Anderson Cancer Center, Houston, TX; ²Datus LLC, Houston, TX and ³Memorial Sloan Kettering Cancer Center, New York, NY.

Background: The majority of women undergoing contralateral prophylactic mastectomy (CPM) Overestimate their risk of developing a contralateral breast cancer and incorrectly believe the CPM will substantially improve their overall survival. Using the results of our published micro-simulation decision-analytic model (Davies et al. Breast Cancer Res, 2016), we created and tested a CPM decision support tool to provide patients and breast cancer surgeons with individualized estimates of contralateral breast cancer risk and overall mortality.

Methods: The CPM decision support tool had four entry parameters from the micro-simulation model (age, family history of breast cancer, estrogen receptor status, and stage), and a visual depiction of outcomes using icon arrays for chances of developing a contralateral breast cancer and overall mortality with and without CPM. A user-centered design strategy was used with input and iterative refinement from stakeholders, i.e., breast cancer surgeons, patient advocates and breast cancer survivors. The tool was field-tested at MD Anderson Cancer Center with 5 breast cancer surgeons each using the tool with 5 breast cancer patients considering CPM (25 total). Patients completed a knowledge survey immediately before and after viewing the tool and the Decisional Conflict Scale (DCS) after viewing the tool. Surgeons completed the System Usability Scale (SUS) and ratings of the acceptability of the tool.

Results: The mean age of patients was 58 years. All patients reported the tool was helpful in making a decision about CPM and would recommend it to others. Knowledge of breast cancer and key CPM facts increased from before to after using the tool (64% vs. 75%, respectively, P<0.05). The mean score on the DCS was 10.5 (standard deviation =14.3) indicating patients were overall sure about the CPM choice. The majority (72%) of patients were unsure of their interest in CPM before viewing the tool. After viewing the tool, 13 (52%) of patients indicated they did not want CPM, 4 (16%) indicated they wanted CPM, and 8 (32%) remained unsure. Surgeons rated the tool as having a positive impact on the decision-making process and SUS scores were highly favorable (mean 93 on 0-100 scale, with 100 indicating highest usability).

Conclusion: The CPM decision tool had high overall patient satisfaction and improved knowledge about CPM without affecting decisional conflict. Decision support tools may be used to improve the quality of decision-making about CPM by providing surgeons and their patients with useful individualized information about CPM's impact on relevant clinical outcomes, which may lower the incidence of CPM.
Reduced sedentary time intervention for breast cancer survivors: objectively-measured outcomes for activity and metabolism

Rachel K Walker¹, Rich Viskochil¹², Ruth Barham³, AnnMarie Moraitis¹, Jeanne Gagliarducci² and Grace Makari-Judson³⁴.
¹University of Massachusetts-Amherst, Amherst, MA; ²Huntsman Cancer Institute, Salt Lake City, UT; ³Baystate Regional Cancer Program, Springfield, MA and ⁴Tufts University School of Medicine, Boston, MA.

Physical activity (PA) promotion and sedentary behavior reduction among cancer survivors is a national priority and the number of PA-based behavioral interventions has expanded considerably in recent years. However, due in part to past limitations related to precise quantitative measurement of sedentary behaviors, there have been relatively few trials focused on reduction of sedentary time among cancer survivors. Additionally, many PA interventions rely on clinic-based coaching, which is both time-intensive and unrealistic for many clinics. The purpose of this study was to investigate the effects of a home-based 6-week reduced sedentary time intervention (RSTI) in breast cancer survivors who had completed primary treatment. Questionnaires, anthropometric measures, fasting blood glucose, lipid profiles and other cancer-relevant biomarkers, and an oral glucose tolerance test to assess dynamic insulin were completed at baseline and post-intervention. Participants wore ActivPALs (on right thigh) for 7 days at baseline and post-intervention. The mailed RSTI included tailored feedback on PA and sedentary habits and provision of personalized visual displays generated from baseline ActivPal data, with specific tips for how to reduce sedentarism through environmental modifications to home and work spaces (example: moving your printer from next to your desk to down the hall).

Eligibility criteria included: females ages 20-80; not meeting national exercise guidelines (150 minutes per week); diagnosis of Stage I-III breast cancer treated >6 months and <5 years prior; overweight or obese (BMI >25); no history of diabetes. Sixteen enrolled and 13 completed the study. Average BMI at baseline was 31.9 and all participants’ daily step counts were significantly below national recommendations (mean=6190 steps/d, SD: 2086 steps/d). Post-intervention changes from baseline were analyzed using non-parametric statistics. No statistically significant changes in daily bouts of sedentarism, energy expenditure, or total steps were detected, although participants’ mean daily steps post-intervention were 6326/d (SD: 2788/d), still well below recommended guidelines. Leptin levels also showed a significant reduction pre/post (p<0.01). Results indicate that similar home-based RSTIs are safe, acceptable to survivors, and feasible to implement by cancer center staff. Further research with larger samples is required to establish efficacy and effect sizes for the intervention. A larger intervention dose may be required to see clinically-meaningful changes in sedentarism, daily activity, and metabolism.
isomiR-140-3p-regulated mevalonic acid pathway as a potential target for prevention of triple negative breast cancer

Anjana Bhardwaj\textsuperscript{1}, Harpreet Singh\textsuperscript{1}, Celestine M Trinidad\textsuperscript{1}, Constance Albarracin\textsuperscript{1}, Kelly K Hunt\textsuperscript{1} and Isabelle Bedrosian\textsuperscript{1}. \textsuperscript{1}The University of Texas MD Anderson Cancer Center, Houston, TX.

**Background:** Prevention of triple negative breast cancer (TNBC) is hampered by lack of knowledge about the drivers of tumorigenesis. **Methods:** In order to identify molecular markers and their downstream networks that can potentially be targeted for TNBC prevention, we analyzed small RNA and RNA sequencing of a cell line model that represents early stages of TNBC development. We identified direct gene targets of an isomiRNA and using cell based and in vivo model systems we demonstrate the utility of targeting downstream pathways for prevention of TNBC. **Results:** These analyses showed that 5'isomiRNA of miR-140-3p (miR-140-3p-1) were deregulated in the normal-to-preneoplastic transition. We also identified novel direct gene targets of miR140-3p-1, HMG-CoA reductase (HMGCR) and HMG-CoA synthase 1(HMGCS1), key enzymes in the cholesterol biosynthesis pathway, and found that these too are deregulated in the normal to preneoplastic transition, resulting in activation of the cholesterol synthesis pathway. Upregulation in the cholesterol pathway creates a metabolic vulnerability that can be targeted with the statin class of inhibitors. Consistent with this hypothesis, we found direct targeting of miR-140-3p-1 and its downstream pathway by fluvastatin inhibits growth of these preneoplastic MCF10.AT1 cells. However, although, fluvastatin inhibited the growth of MCF10.AT1-derived xenografts, histological progression remained unchanged. The cholesterol pathway is highly regulated, and HMGCR enzymatic activity inhibition is known to trigger a feedback response leading to restoration of the pathway. Indeed, we found fluvastatin treatment induced HMGCR transcript levels in the explanted xenografts, with higher transcript induction directly correlated with the degree of histological progression of lesions, indicating an adaptive resistance mechanism that circumvents statin targeting of HMGCR. Therefore, we hypothesized that dual targeting of HMGCR and the feedback loops are necessary to overcome this adaptive resistance. To test this hypothesis, we generated MCF10AT1 cells resistant to fluvastatin. We then treated these resistance AT1 cells with an activator of AMP-activated protein kinase (AMPK), a brake in the cholesterol feedback pathway. AMPK activation by aspirin effectively abrogated the statin-induced upregulation of HMGCR and sensitized these resistant cells to fluvastatin. **Conclusions:** Our preclinical data suggests that the statin treatment induced homeostatic upregulation of the cholesterol pathway is a barrier to effective chemoprevention with statins. However, our results also suggest that this adaptive resistance mechanism can be abrogated by combined treatment with statin and AMPK activators such as aspirin. Clinical studies of this combined regimen should be considered in high risk patients.
Background: Screening guidelines for women with a family history of breast cancer without a known causative gene mutation differ per country. No randomized controlled trial has been performed to assess the optimal screening strategy for these women.

Methods: In twelve centers, 1355 women aged 30–55 years with a cumulative lifetime risk of ≥20% without a BRCA1/2 mutation were randomized into two arms. From January 2011 until December 2017, women in the MRI-arm received yearly MRI-screening, clinical breast examination (CBE), and mammography every other year; and in the Mx-arm yearly mammography and CBE. Outcomes were number and stage of detected breast cancers, sensitivity, specificity and positive predictive value, and stratified by screening round and by mammographic density.

Results: After on average 4.3 screening rounds per woman, in the MRI-arm (N=675) compared to the Mx-arm (N=680) more breast cancers were detected (41 versus 14, \( p < 0.001 \)), invasive cancers were smaller (median size 8 versus 17 mm, \( p = 0.006 \)) and less often node positive (20% versus 71.4%, \( p = 0.019 \))(Table). In the MRI-arm, sensitivity was slightly higher (95.1% versus 92.9%, \( p = 1 \)), and specificity significantly lower (82% versus 90.1%, \( p < 0.001 \)), compared to the Mx-arm. After two rounds, specificity improved for both modalities (87.1% for MRI; 93.0% for Mx; \( p < 0.001 \)) and no ≥T2 tumors or interval cancers occurred in the MRI-arm. All tumors ≥T2 were in the two highest density categories. MRI detected more small invasive tumors than Mx across all density categories.

Conclusions: In real-life practice the MRI-arm detected more, relevantly smaller, and far more often node negative tumors, and also at low density in women with a familial risk for breast cancer.

Reduced incidence of breast cancer with testosterone implant therapy: A 10-year cohort study

Rebecca L Glaser1,2, Anne E York3 and Constantine Dimitrakakis4,5. 1Millennium Wellness Center, Dayton, OH; 2Wright State University Boonshoft School of Medicine, Dayton, OH; 3York Data Analysis, Seattle, WA; 4Athens University Medical School, Athens, Greece and 5National Institutes of Health, NICHD, Bethesda, MD.

Introduction: There is evidence that androgens are breast protective and that testosterone (T) therapy treats many symptoms of hormone deficiency in both pre and postmenopausal patients. However, there is a lack of data on the effect of long-term T therapy on the incidence of breast cancer.

Methods: A ten-year prospective, IRB approved study (Dayton study) was designed to investigate the incidence of breast cancer (BCA) in women with symptoms of hormone/androgen deficiency who were treated with subcutaneous testosterone (T) implants or, T combined with an aromatase inhibitor, anastrozole, implants (T+A). Breast cancer events during ‘active therapy’ (within 120 days post implant, i.e, clinically effective/therapeutic T levels), and ‘post therapy’ (240 days and 1-year post implant) were reported as incidence per 100 000 person-years. Person-days for each participant were calculated from the date of first T pellet insertion up to the date of cancer registration, the date of death, a set number of days post last implant, or the set date of 31 March 2018, whichever came first. Person-years (p-y) were calculated by dividing (total) person-days by 365.25. Bootstrap sampling distributions were constructed to determine if there were important differences in breast cancer incidence rates between our results and the SEER data. Allowing for patient aging and different cancer rates over the period of the study, the range of expected values based on SEER data was calculated from the age composition of our study patients and the published grouped age breast cancer incidence rates for two time periods, SEER 2006-2011 and SEER 2011-2016.

Results: 1267 pre (23.2%) and post (76.8%) menopausal women, mean age 52.1 ± 8.6 y, were enrolled in the study March 2008-2013 and were eligible for analysis. As of March 2018 there have been 12 cases of invasive breast cancer diagnosed within one year of last T or T+A pellet implant. The incidence of breast cancer at each specified time frame is listed in Table 1. For comparison, the calculated age matched SEER incidence rate is approximately 271/100 000 p-y.

Bootstrap estimates of Dayton and expected SEER incidence rates (per 100 000 P-Y), their standard deviations (sd), the ratio (R) of the Dayton incidence rate to the SEER and its sd for various time frames.
Conclusion: Long-term therapy with T or T+A subcutaneous implants, used to treat symptoms of hormone deficiency, reduced the incidence of breast cancer by 59% during active therapy (p < 0.001), which continued up to one year following the last pellet implant, 36% reduction at 1-year (p < 0.001).
A phase III, randomized, multi-centre, double-blind, placebo-controlled clinical trial of F-627 in women with breast cancer receiving myelotoxic chemotherapy

John Glaspy¹, Tom Tang², Dean Rutty³, Xiaoqiang Yan², Igor Bondarenko⁴ and Olga Burdaeva⁵. ¹UCLA School of Medicine, Los Angeles; ²Generon (Shanghai) Corporation, Shanghai, China; ³Everest Clinical Research Inc., Markham, Canada; ⁴Dnepropetrovsk Medical Academy, Dnepropetrovsk, Ukraine and ⁵Arkhangelsk Regional Clinical Hospital, Arkhangelsk, Russian Federation.

Purpose: Neutropenia is a common side effect of chemotherapy. Chemotherapy-induced neutropenia increases a patient's risk of infection and disrupts cancer treatment. F-627, a rhGCSF-FC dimer, is a once-per-cycle therapy for the preventive management of neutropenia. The objective of this phase 3 multinational study was to evaluate the efficacy and safety of F-627 given as a single fixed dose pre-filled syringe.

Patients and Methods: This trial was conducted at 16 study centers in the United States, Ukraine, Russia, and Hungary. A total of 122 women with stage II-IV breast cancer undergoing 4 cycles of myelotoxic TA chemotherapy treatment (docetaxel + doxorubicin) were randomized. Among them, 83 subjects received F-627, 39 subjects received placebo in cycle 1, and all subjects received F-627 in cycles 2, 3, and 4. For efficacy and patient safety, absolute neutrophil count (ANC) post-chemotherapy was closely tracked; electrocardiogram and other laboratory values were also monitored. All AEs were noted and followed to resolution or stabilization. Overall, 118 subjects completed the study and 4 subjects discontinued prematurely due to TEAE including 1 (2.6%) subject from placebo arm and 3 subjects (3.6%) from F-627 arm. All 122 subjects were analyzed for efficacy and safety.

Results: F-627 administration significantly reduced the duration of Grade 4 (severe) neutropenia in chemotherapy cycle 1 (P<0.0001), the mean treatment difference was 2.8 days (1.1 days vs 3.9 days). F-627 administration also resulted in lower incidence rate and shorter duration of Grade 4, Grade 3 and Grade 2 neutropenia. Importantly, F-627 treatment significantly reduced the incidence of febrile neutropenia (FN) (P<0.0016). The incidence of FN was 4.8% (F-627) vs 28.2% and 25.6% (placebo) across all cycles and cycle 1 respectively. Subjects from F-627 arm also had a lower rate of antibiotic medication and pain medication use. In this study, F-627 was shown to be safe and well tolerated with no deaths, no injection site reactions and less gastrointestinal AEs (diarrhea, vomiting, stomatitis and gastritis). In cycle 1, the five most common F-627 TEAEs (incidence rate >10% in the F-627 arm and ≥2% higher than placebo arm) were: leukopenia, anemia, thrombocytopenia, nausea and alopecia. Over all cycles, there were 17 SAEs from 15 subjects of which 14 were FN.

Conclusion: A single subcutaneous injection of F-627 provided effective neutrophil support to breast cancer patients undergoing high dose chemotherapy, significantly reducing the duration and incidence of severe neutropenia and febrile neutropenia while maintaining a sound safety profile.
Estrogen-alone based hormone replacement therapy (HRT) reduces breast cancer (BrCa) incidence and mortality whereas estrogen plus progestin Provera based HRT increases both BrCa incidence and BrCa mortality: A comparative analysis of Women's Health Initiative trials

Joseph Ragaz1, Hong Qian2, Hubert Wong1,2, Kenneth S Wilson3, Shayan Shakeraneh4 and John J Spinelli5. 1School of Population and Public Health, University of British Columbia (UBC), Vancouver, BC, Canada; 2Centre for Health Evaluation & Outcome Sciences, Providence Health Care Research Institute, St. Paul's Hospital, University of British Columbia (UBC), Vancouver, BC, Canada; 3BC Cancer Agency, Victoria, BC, Canada; 4Institute on Aging & Lifelong Health, University of Victoria, Delta, BC, Canada and 5BC Cancer Agency, Vancouver, BC, Canada.

OBJECTIVE: To quantitate breast cancer incidence (BrCa-I) and mortality (BrCa-M) outcome differences between the two Women's Health Initiative (WHI) HRT trials,1,2 the ratio of hazards was calculated for estrogen-alone based hormone replacement therapy (E-HRT) vs. placebo (P), and E + progestin Provera (ProgProv) combination HRT vs. P trials.

METHODS: Hazard ratios (HR) of BrCa-I and BrCa-M and 95% confidence intervals (CI) were obtained from both WHI HRT trials. Subsequently, to compare BrCa outcomes between E-HRT vs. E + ProgProv, the ratios of HRs between the trials (HR1/HR2) were estimated separately for i. BrCa-I all women, ii. BrCa-I low Gail score (Gail score <1.75*), and iii. BrCa-M. The 95% CI was derived through logarithmic transformation of the 95% CI originally reported.

RESULTS:

<table>
<thead>
<tr>
<th>Outcome Comparison, the two WHI HRT randomized trials. Ratio of Hazards, BrCa Incidence and BrCa mortality</th>
<th>E-HRT vs. P, HR1 (95% CI)</th>
<th>E-HRT + ProgProv vs. P, HR2 (95% CI)</th>
<th>HR1/HR2 (95% CI)</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>BrCa-I All Woman1</td>
<td>0.77 (0.62-0.95)</td>
<td>1.25 (1.07-1.46)</td>

<td>0.38 (0.20-0.75)</td>
<td>0.004</td>
</tr>
</tbody>
</table>

*Gail score <1.75; HRs calculated from Reference 1, Figure 3

CONCLUSIONS: Our calculations show that the different outcomes between the two WHI HRT trials, estimated as ratio of hazards, are highly significant on statistical basis, both for BrCa incidence and for BrCa mortality. These findings highlight the potential carcinogenic impact of ProgProv and the major public health benefits of HRT based on E alone.

Association between the UGT2B17 gene deletion, exemestane metabolites and vasomotor QOL in women participating on the MAP3 prevention trial

Harriet Richardson1,2, Braden Knight1, Gang Chen3, Shaman Luo3, Thomas Massey1, Paul E Goss4 and Philip Lazarus3. 1Queen’s University, Cancer Research Institute, Kingston, ON, Canada; 2Canadian Cancer Trials Group, Kingston, ON, Canada; 3Washington State University, Spokane, WA and 4Dana-Farber/Harvard Cancer Center, Boston, MA.

Background: The aromatase inhibitor Exemestane (EXE) reduces the risk of breast cancer in postmenopausal women. However, participants have varied responses to EXE treatment in terms of efficacy and toxicity, possibly due to differences in EXE metabolism. One of the main elimination pathways for EXE is through glucuronidation by UGT2B17. Aims: This project examined the relationship between the UGT2B17 gene deletion, EXE metabolites and menopause-related quality of life (QOL) in postmenopausal women. Hypothesis: Glucuronidation of the main EXE metabolite, 17-dihydroexemestane (17-DHE), is reduced in women with the UGT2B17 double gene deletion, leading to increased circulating 17-DHE and potential toxicity. Methods: This study included 3576 women nested within the CCTG MAP.3 trial, who were allocated to EXE or placebo treatment groups. Genotyping analysis was conducted with baseline blood cell DNA using real-time PCR and allelic discrimination. Women who were homozygous null were considered “exposed”. In addition to EXE, EXE metabolites including 17-DHE and glucuronidated 17-DHE (17 DHE-Gluc) were analyzed from serum by UPLC/MS. Ratios of the main metabolites (17-DHE/EXE) and glucuronidated metabolites (17-DHE-Gluc/17-DHE) were standardized, using an autoscaling method. Metabolite levels that were below the detection limit were replaced by “half the detection limit for that metabolite”. Women had the outcome if they experienced a clinically meaningful (>10%) worsening in vasomotor QOL from baseline within the first year. Modified Poisson regression models were used to calculate the relative risks for both the (1) UGT2B17 gene deletion and (2) metabolite ratios and vasomotor QOL. Results: Ten percent of participants exhibited the homozygous UGT2B17 deletion genotype. There was no significant relationship between the UGT2B17 deletion polymorphism and worsened vasomotor QOL (RR= 1.04, 95% CI: 0.93, 1.17), adjusted for age, race and treatment. Among women with no vasomotor symptoms at baseline but extremely bothersome symptoms at follow-up (incident vasomotor symptoms), there was a suggestive but non-significant protective effect of the UGT2B17 deletion (RR=0.61, 95% CI: 0.32-1.19). This effect was more extreme in the placebo arm (RR=0.20) than in the EXE arm (RR=0.78; p-interaction=0.17). Among women on EXE, levels of EXE and 17-DHE were not different between UGT2B17 genotypes, but levels of 17-DHE-Gluc were significantly lower for the UGT2B17 deletion genotype (p=<0.0001). An increasing ratio of 17-DHE-Gluc/17-DHE [per standard deviation (SD) increase] had a borderline protective effect against worsened vasomotor QOL (RR=0.94, p=0.049), adjusted for age and race. In contrast, an increasing ratio of 17-DHE/EXE (per SD increase) was associated with a small but significant increased risk of worsened vasomotor QOL (RR=1.02, p=0.01). The effect observed for the 17-DHE/EXE ratio was stronger for very bothersome incident vasomotor symptoms at follow-up, but this did not reach statistical significance [17-DHE/EXE (per SD increase): RR=1.36, p=0.12]. Conclusion: EXE metabolite levels could potentially be used as a biomarker for extreme vasomotor QOL changes in breast cancer chemoprevention settings using EXE.
Estrogen-based hormone replacement [HRT] therapy is substantially more effective than tamoxifen in reducing breast cancer mortality and breast cancer case fatality ratio: Emergence of a new paradigm

Joseph Ragaz1, Shayan Shakeraneh2, Hong Qian3, Kenneth S Wilson4, Hubert Wong1,3 and John J Spinelli5. 1School of Population and Public Health, University of British Columbia (UBC), Vancouver, BC, Canada; 2Institute on Aging & Lifelong Health, University of Victoria, Delta, BC, Canada; 3Centre for Health Evaluation & Outcome Sciences, Providence Health Care Research Institute, St. Paul's Hospital, University of British Columbia (UBC), Vancouver, BC, Canada; 4BC Cancer Agency, Victoria, BC, Canada and 5BC Cancer Agency, Vancouver, BC, Canada.

OBJECTIVE: To compare, in the setting of breast cancer (BrCa) prevention, the impact of estrogen-based hormone replacement therapy (E-HRT) vs. tamoxifen (TAM) on breast cancer mortality (BrCa-M) and breast cancer case fatality ratio (BrCa-CFR), by analyzing data from the Women's Health Initiative Trial 2 (WHI HRT Trial 2, E-HRT vs. placebo [P])1 and the International Breast Cancer Intervention Study 1 (IBIS-1), TAM vs. P.2

METHODS: Hazard ratios (HR) and confidence intervals (CI) for BrCa incidence and mortality were extracted from the original WHI HRT Trial 2 and IBIS-1 trials.1,2 BrCa-CFRs were estimated by dividing the mortality HR by the incidence HR. Subsequently, to compare E-HRT vs. TAM outcomes, the ratios of HRs (HR1/HR2) between the two trials were estimated separately for BrCa-M and BrCa-CFR. The 95% CI was derived through logarithmic transformation of the 95% CI originally reported.

RESULTS:

</table>

CONCLUSIONS: While acknowledging between-trial comparisons including eligibility differences, E-HRT yields significant reductions in BrCa mortality and case fatality as compared with TAM (54% and 58% respectively). These unexpected breast cancer mortality reductions represent major public health gains, additional to the already known superiority of E-HRT over TAM in terms of skeletal fracture rates and Alzheimer's dementia mortality reduction, and, in women entering menopause, also of cardiac and all-cause mortality reductions.

Impact of educational workshops on patient-provider communication: Results from the *Frankly Speaking about Cancer*: Metastatic Breast Cancer educational workshops

Heather R Hollen¹, Claire M Saxton¹, Maria B Gonzalo¹ and Alexandra K Zaleta². ¹Cancer Support Community, Washington, DC and ²Research and Training Institute, Cancer Support Community, Philadelphia, Philadelphia, PA.

Patient education about metastatic breast cancer can help patients and caregivers in interactions with their health care team and provide tools to deal with the psychosocial effects of the disease. This analysis explores participants' experiences related to the gains from Cancer Support Community's national evidence-based educational program, *Frankly Speaking about Cancer*: Metastatic Breast Cancer. This comprehensive psychosocial education program, created for people diagnosed with metastatic breast cancer and their families, provides information about current treatments, side-effect management, and social and emotional challenges of an advanced breast cancer diagnosis.

Participants from 43 workshops across the country between 2014 and 2017 completed program evaluation surveys on factors including: pre- and post-workshop knowledge and intentions for patient-provider communication post-workshop. In total, 427 individuals attending in-person Frankly Speaking about Cancer: Metastatic Breast Cancer workshops nationwide assessed their experiences and learnings during the educational workshops. Survey questions focused on how participants currently met their informational and assistance needs in regard to metastatic breast cancer and whether the workshop was associated with positive gains. Descriptive analyses and pre-and post-workshop comparisons were conducted to assess workshop outcomes.

71% of participants were cancer patients/survivors; the remainder served in the caregiving capacity and included spouses/partners (11%), family members (10%), and friends (8%). The average age of participants was 47 years old (s.d.= 24 years). Among patients/survivors, 70% received the diagnosis within the last two years; and 65% reported being highly involved in their treatment decisions. The most common treatment side effects included anxiety (10%), pain (10%), depression (10%) and fatigue (15%). The majority of respondents (72% patients/survivors and 81% caregivers) reported experiencing emotional distress due to their/their loved one's cancer. Most workshop participants (83%) reported gaining a high or very high level of knowledge about metastatic breast cancer, which was a significant increase compared with pre-workshop levels ($\chi^2 = 13.2, p < .05$).

Caregivers were equally as likely as patients/survivors to report that as a result of their participation, they gained knowledge about metastatic breast cancer treatment options, confidence to participate in treatment decision-making with their health care team and to ask questions about side effects of metastatic breast cancer and its treatment. Finally, 73% of cancer patients/survivors and 78% of caregivers reported that as a result of the workshops, they felt better prepared to emotionally cope with their metastatic breast cancer experience.

These findings indicate that educational workshops can play a role in enhancing patients' self-perceived knowledge about metastatic breast cancer and empowering patients and caregivers to become active participants in their treatment decisions. These enhancements can, in turn, support caregivers in their interactions with their health care team and provide tools to manage the psychosocial effects of the disease.
Facebook Live social media programming: engaging and reaching young breast cancer survivors

Michelle R Esser¹, Jean J Rowe¹, Megan L McCann¹, Maggie Nicholas-Alexander¹, Emily P Helck¹ and Stacy M Lewis¹. ¹Young Survival Coalition, New York, NY.

Background: Young Survival Coalition (YSC) is a nonprofit organization that provides resources, connections and outreach to young women diagnosed with breast cancer. Educating constituents is a priority to ensure that they receive information they need in a manner that is timely, engaging and convenient. Young women with breast cancer are in a variety of different life stages and have competing demands for their time. Some are in treatment or recuperating from surgery; others are working or pursuing higher education; and some are raising children. It is not feasible to reach all of them at the same time in the same manner.

Methods: YSC evaluated various modes of communicating and providing information to its constituents. Convenience to constituents, ease of use for YSC staff and affordability were key considerations. Ultimately, YSC decided to use Facebook Live as its platform via BeLive TV, using a social media strategy to advertise the programming. After the live event, the recorded program is housed on YSC’s YouTube channel as enduring educational material.

Results: YSC has held 13 Facebook Live events since the beginning of 2018 on a variety of topics ranging from recent legislation to YSC programs to wellness. The data from these “live” events show that although the number of live viewers is not high, the amount of engagement from these posts, as well as the number of video views after the live event are significant. Total video views from January 1st to June 25, 2018 are 17,000. See Table 1.

</table>

In addition, the programs were efficient for staff to plan, coordinate and manage at reasonable cost.

Conclusion: Facebook Live is an easy-to-use method of programming that reaches a substantial number of YSC constituents in a manner that is engaging and convenient. Data from these programs provide evidence regarding the viability of this technology as a means of providing extensive education and support.
Metastatic breast cancer alliance’s patient education and access to trials: Perceptions and actions

Deborah J Vollmer Dahlke1, Matthew L Smith1, Gang Han1, Marcia G Ory1 and Elly Cohen2. 1TX A&M University’s Center for Population Health and Aging, College Station, TX and 2University of California at San Francisco, San Francisco, CA.

Background
Those living with metastatic breast cancer (MBC) have distinct and shifting concerns in regard to education and decision making in considering clinical trials as a treatment option. Clinical trials designs, are becoming increasingly complex, and many patients have concerns for biomarker requirements

Aims/Research Questions
· What is the status of MBCA advocacy members’ and partners’ digital information, education and access to metastatic breast cancer trials?
· What plans do MBCA members/partners have for the next 6-18 months to educate and inform their constituents for the 2018 rollout of BreastCancerTrials.org’s (BCT) Metastatic Trial Search (MTS) and Metastatic Trial Talk (MTT) and other trial matching systems?
· What are the top 5 barriers regarding trial enrollment?
· What are best practices for MBC trial education?

Research Methodology and Design
A comprehensive analysis was conducted comprising both secondary and primary research to inform these specific aims. Secondary research was conducted using previous capture of MBCA online digital resources and strengthened to include additional research on MBCA members and partners online resources including pages specifically devoted to clinical trials and metastatic clinical trials.

Mixed methods approaches include:
1) An assessment of MBCA members’ and partners’ digital media presence regarding MBC trials using a standardized form and rating system, and an analysis of MBCA members 2017 use of MTS using BCT secondary data;
2) Structured, recorded interviews with selected MBCA members/ partners, sharing the results of the assessments and querying them regarding their future plans and perceived barriers; and
3) Mixed methods analyses of the interview recordings using DeDoose to assess and articulate key trends and perceptions.

Statistical Methods
Simple frequency percentages and means were used in the assessment rankings of the MBCA members. DeDoose was used to provide mixed method analyses of the MBCA member and partner interviews.

Results
Analysis of the MBCA members and partners websites and digital media showed that, increasingly, both groups use the full variety of digital media to educate their constituents regarding MBC clinical trials. The 13 MBCA advocacy members providing online access to BreastCancerTrials’ MTS in 2017 provided 97% of the traffic to the MTS trial matching service. System types accessing the MTS widget were 57.3% desktops, 28.6% mobile devices and 14% tablets. Table 1 shows assessment totals of 5 categories of the 13 MBCA advocacy group members’ websites using MTS as compared to the 19 MBCA members not using the widget. Table 2 shows the 2017 usage of BCT’s MTS with 97% of the page views coming from MBCA members.

Improving breast health literacy through an innovative breast cancer awareness campaign using "Know Your Lemons" materials in Malaysia

Nur Aishah Mohd Taib, Tania Islam, Tin Tin Su, Suhaida Musthaffa, Noraiizam Abdullah Din, Zarinae Rahman, Kamar Noraini BT Mohamed, Sarinder Kaur, Jasmine Filza, Fatin Shaheera and Corrine Ellsworth Beaumont. 1Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia; 2Institute of Biological Sciences, University Malaya, Kuala Lumpur, Malaysia and 3Worldwide Breast Cancer, Lewisville.

Background: Breast Cancer (BC) is the most common cancer in Malaysia, which has the worst survival rate in Asia Pacific. Main drivers identified in prior research include women presenting with advanced or late-stage disease, poor adherence to treatment and socio-cultural barriers. Factors accounting for late presentations include lack of awareness and information about basic symptoms of cancer and poor access to early detection and treatment. Breast cancer awareness campaigns have been done but few evaluations conducted. The "Show You Care, Be Aware" campaign was held on the University of Malaya campus from October 8-20, 2017 using “Know Your Lemons” education materials in awareness booths, public talks and forums. KYL visual materials in Malay and English language contain information on the normal breast, 12 BC symptoms, breast self-exam and screening and diagnostic pathways. Evaluation was conducted.

Aim: Evaluate improvement in breast health-recognizing symptoms and diagnostic care pathways of breast cancer-after implementing the "Know Your Lemons"(KYL) campaign.

Methods: Quasi-experimental research (n=679). KYL materials were forward and backward translated by 2 native bilingual individuals for accurate context and content and fitting the KYL leaflet design; self-designed questionnaire assessed effectiveness of the educational material; educational intervention sessions displayed KYL materials (leaflets, posters, banners) in awareness booths in Faculty of Arts, Science, Medicine, Islamic Studies and University Malaya Medical Centre; discussion on leaflets with Q&A and practical demonstrations of breast self-examination on a dummy were done in booths; questionnaire was administered via face to face interview; data analyzed via SPSS20; descriptive and Wilcoxon matched paired signed rank test was performed to analyze patients pre- and post knowledge at a significance level of <0.05.

Results: 72% (n=492) of participants were Malay, 19%(n=119) Chinese and 10%(n=68) Indians and others. Majority of participants were female (94.2%), age 30 or below (61%), single (62.9%), had college or university education (85.7%), some 10% had primary school education. Majority of participants (96.2%) stated language used in the "KYL" poster or leaflets was clear and understandable; 95.3% thought materials were attractive and drew attention; and 89.2% thought materials were acceptable in Malaysian culture. Materials improved knowledge on the process of detecting BC (96.5%). 92.8% participants either agreed or strongly agreed, after viewing the 12 BC symptoms in KYL materials, they felt more confident recognizing symptoms of BC. There was an increase in self-reported knowledge of BC; mean scores before and after exposure to KYL materials were 2.83 versus 4.30 respectively (p <0.001).

Conclusions: Health education using KYL materials increases breast cancer awareness and the visuals are acceptable amongst an urban and highly educated community in Malaysia. Developing and implementing a BC awareness program based on KYL materials can enhance awareness and confidence in the Malaysian public towards early detection of breast cancer. Future research in lower educated and rural communities in Malaysia is warranted.
Co-survivors: A continuing need for education and support

Michelle R Esser1, Jean J Rowe1, Megan L McCann1, Maggie Nicholas-Alexander1, Emily P Helck1 and Stacy M Lewis1. 1Young Survival Coalition, New York, NY.

Background: Young Survival Coalition (YSC) is a nonprofit organization that provides resources, connections and outreach to young women diagnosed with breast cancer. Since 2016, YSC has increased its information and support for the family, friends, adult children (18 and older) and spouses/partners of these young women, collectively called “co-survivors.” In 2016, YSC conducted a survey of its co-survivors (CS) to better understand their information and support needs. Previously reported results influenced the creation of a private Facebook group for CS and additional workshops and events at the YSC National Summit. The Summit is an annual conference for young women affected by breast cancer, their loved ones and healthcare providers.

Methods: In order to evaluate its recent efforts directed to CS and learn more about them, YSC conducted an online follow-up survey that opened in early 2018.

Results: Sixty responses were received, of which 34% were spouses, 23% friends, 25% parents, 15% siblings and 3% adult children. These figures represent a higher proportion of respondents who were parents and friends compared to the 2016 survey. Survey respondents were mainly female (65%, compared to 46% female in 2016) and white (86%, compared to 75% in 2016). Most respondents were a CS of a young woman with early stage disease (61%), not in active treatment (43%) and within two to five years after diagnosis (56%). Survey results showed that CS felt isolated frequently (29%) or at times (35%), felt guilty asking for help very much (26%) or to some extent (51%), felt anxious or depressed as a result of being a co-survivor very much (40%) or to some extent (48%) and had sleep difficulties to some extent (52%) or very much (23%). Most respondents were aware of CS programming offered by YSC (44% to some extent; 37.5% very much) although 43% had not participated in any YSC offerings. Of those who had participated, 36% attended the Summit, 30% in the private Facebook group, and 6% in peer-to-peer matching. Thirty-four percent receive YSC's “Just for You” CS newsletter/blog, a new initiative started after the first CS survey, although 19% didn't know it existed. To date, 2208 CS receive this newsletter. Fifty-seven percent would like a CS guidebook and, in commentary, a few suggested a half-day retreat at the Summit.

Similar to the 2016 survey, over two-thirds (78%) preferred to receive important information via an email newsletter with Facebook (54%) as the next highest response. Topics of greatest interest included self-care (62%), managing day-to-day details (47%) and talking with kids (36%).

Conclusion: CS of young women diagnosed with breast cancer are a population interested in resources and support. Initiatives started after the 2016 YSC survey are being utilized with continued room for growth. YSC intends to use the results of its research to refine and expand its programmatic offerings to this varied population.
A patient-centered approach to education: Evaluating and improving radiation treatment education in breast cancer patients

Colton J Ladbury¹, Jane W Ridings² and Darryl Yancy². ¹Colorado Springs Branch, University of Colorado School of Medicine, Colorado Springs, CO and ²University of Colorado School of Medicine, Colorado Springs, CO.

Introduction
Breast cancer patients rapidly receive large amounts of information from multiple practitioners during treatment. It is therefore essential that education be presented in an appropriate manner to promote satisfaction and retention of important facts regarding treatment. Educational materials at the Memorial Radiation Oncology Department have not been evaluated by patients, and it is unclear how effectively and efficiently they express information. We hypothesized that satisfaction was already very good, but patients lacked knowledge of key aspects of their radiation treatment. This quality improvement project aimed to achieve a patient comprehension of key treatment-related concepts of 75% by March 2018 via evaluating and improving educational materials.

Methods
A survey was designed to evaluate patient satisfaction with and comprehension of educational materials. The survey inquired about satisfaction with several specific aspects of their education and tested understanding of concepts that impact treatment. The survey was administered to all breast cancer patients over a three-month period. Those results were used for a PDSA cycle to implement improvements. These improvements included eliminating redundant resources, reemphasizing essential concepts throughout treatment, and consolidating important concepts from the materials into a more accessible one-page summary sheet. Following those changes, the surveys was adapted and administered to every breast cancer patient over another three-month period, which were analyzed to evaluate the effectiveness of and satisfaction with the interventions. Statistical comparisons were performed using Student’s t-test and Fisher’s exact test.

Results
Following the interventions, overall satisfaction improved from 97% to 100% (p=1.0). However, 27% and 18% of patients still did not remember receiving an informational letter and physician handout, respectively. On knowledge based questions, average percent correct improved from 52% to 78% (p=<0.001). However, there were areas where comprehension declined following the interventions. Select results of individual survey items are shown below in Table 1:

Table 1:

Conclusions
A patient-centered approach to developing and delivering patient education can lead to better satisfaction and patient
comprehension, thereby improving compliance and encouraging patient engagement, which has a positive impact on outcomes. Although some education remained unmemorable or improperly emphasized following the interventions, overall trends in comprehension validate tailoring educational materials to patient feedback. In the future, the PDSA cycles will be continued with a focus on addressing persistent educational deficits and identifying further avenues to improve patient retention.
Impact of multidisciplinary team meetings on the management of patients with breast cancer at Cabrini Hospitals in Melbourne, Australia

John Lai¹, Yoland Antill², Gary Richardson¹, Melissa Vereker² and Steven David³. 'Oncology Clinics Victoria, Cabrini Health, Melbourne, VIC, Australia; ²Cabrini Health, Melbourne, VIC, Australia and ³Peter MacCallum Cancer Centre, Melbourne, VIC, Australia.

Introduction: Multidisciplinary meetings (MDM) allow patient management plans to be discussed in the context of multidisciplinary, expert knowledge and experience. MDMs also provide opportunities for clinical trial recruitment. However, the eventual management plan remains at the discretion of the treating specialist. We aim to determine 1) The level of impact of MDM on pre-MDM management plans in patients with breast cancer and 2) The rate of implementation of the breast cancer MDM management plans into clinical practice.

Methods:
Patients with a new diagnosis of unilateral, invasive breast cancer presented at the weekly breast cancer MDMs were prospectively and anonymously enrolled into the study. Patients with bilateral breast cancer and/or a history of breast cancer receiving active treatment are excluded. The impact of breast cancer MDMs on their management plan was evaluated, by comparing pre-MDM management plans to MDM recommendations. Recruitment continued until 50 cases are available for final analysis. Prior to each MDM, study investigators will collect the required information from patients' medical history and histopathology reports to determine a pre-MDM management plan. The MDM recommendations will then be recorded. Any discordance between the pre-MDM management plan and the MDM recommendations will be documented and then scored according to a pre-determined level of impact: low, high or none.

Results:
- 33/50 (66%) cases discussed at MDM showed an impact, with 19/50 (38%) recorded high impact scores and 14/50 (28%) with low impact scores.
- 15/50 (30%) patients had a change in plan after MDM discussion with further investigations recommended, the highest among all modalities (7 with low impact scores, 8 with high impact scores)
- The highest proportion of high impact scores were recorded with recommendations to refer for clinical trial participation (7/8 with high impact scores; 1/8 with low impact score)
- The highest proportion of low impact scores were recorded when recommendations for chemotherapy are made (12/13 with low impact scores; 1 high)
- 11/17(65%) patients with no impact scores recorded were low grade, ER+, node negative breast cancers with recommendations for Endocrine therapy and radiotherapy or Endocrine therapy alone only.
- Three month follow up plans were available for 49/50 patients records, from which 8/49 had a change in management plan. Reasons for change in management plan include the incorporating results of further investigations, consideration of other medical comorbidities, and patient/physician preference.

Effects of online resource to support laypersons' understanding of media reports on breast cancer research

Robin H Pugh Yi, Lisa Rezende, Craig T Dearfield, Piri L Welch and Susan J Friedman. 1Facing Our Risk of Cancer Empowered (FORCE), Tampa, FL; 2University of Arizona, Tucson, AZ and 3Akeso Consulting, LLC, Vienna, VA.

Rationale: Breast cancer is the second leading cause of death among women ages 20 to 39. Approximately 7% of women with breast cancer are diagnosed before age 40. Women age 45 or younger with breast cancer or who are at high risk for breast cancer have distinct health risks and different needs from their older counterparts. Breast cancer risk, etiology, treatment, outcomes, and related survivorship and quality of life concerns often vary between younger and older women. Diagnosis at a young age is associated with higher risk of recurrence, second malignancy, mortality, morbidity, and quality of life issues. Young women with or at high risk for breast cancer need clearly presented information based on sound evidence to help them make informed decisions about their specific health needs. To help women better understand media coverage about new research, Facing Our Risk of Cancer Empowered (FORCE) developed XRAYS (eXamining Relevance of Articles to Young Survivors). XRAYS is an online resource that provides brief articles summarizing recent research relevant to young women with or at risk for breast cancer. XRAYS articles rate the quality and relevance of scientific research and the quality of media reporting on that research.

Objectives: The objectives of the current project were to:
1) conduct an initial test of XRAYS’s effectiveness in improving users’ knowledge about information covered in media reports
2) assess the degree to which XRAYS facilitates awareness of recent research findings
3) Obtain feedback regarding XRAYS’ utility and appeal
4) Use results to inform XRAYS development

Methods and Results: An independent evaluator randomly assigned 21 participants to a treatment (read media article plus XRAYS review) or control (read media article only) condition. Each respondent completed multiple choice pre- and post-intervention tests about information contained in one of three media reports (Two respondents took their written surveys with them. Statistical analyses were conducted on data from the remaining respondents). Results demonstrate that both groups improved between pre- and post-test. The treatment group increased knowledge significantly more than the control group.

</tbody>
</table>
Participants also contributed to one of three focus groups. Focus group results indicate that XRAYS is a valuable resource for identifying relevant recent research findings and for explaining limitations in research methods, relevance, and reporting quality. Results also indicate that it is critical for XRAYS to be brief, use non-technical language, and address the most recent trends in media coverage. FORCE is using focus group feedback to guide decisions about XRAYS content, format, and dissemination. FORCE will collect additional data to confirm test findings and to assess effects of XRAYS on understanding of evidence quality.
Military sexual trauma is associated with an increased prevalence of mastectomy versus breast conserving surgery in a population of female veterans with early stage breast cancer

Lauren J Oshry1,2, Ko Naomi2 and Gerber R Megan1. 1Department of Veterans Affairs (VA) Boston Healthcare System, Boston, MA and 2Boston University School of Medicine, Boston, MA.

Background:
The National Accreditation Program for Breast Centers (NAPBC), in a 2014 statement of standards, endorsed breast conservation surgery (BCS) for women with AJCC stage 0, I, or II breast cancer, with a target of 50% BCS. Women comprise the fastest growing segment of Veteran's Health Administration (VA) enrollees, and have high rates of trauma exposure including military sexual trauma (MST). The VA conducts universal screening of all Veterans for MST. Implications for medical care, e.g. an increased rate of hysterectomy among survivors of MST, have been reported. While the numbers of breast cancers treated in VA are relatively small compared to non-VA centers, a trend toward decreasing rates of BCS in VA from 2000-2006 has been reported. Reasons for declining rates of BCS within VA, and the lower rates of BCS in the VA compared to the private sector remain unclear. The objective of this study was to identify determinants of mastectomy versus BCS in women Veterans with early stage breast cancer and to examine whether history of MST was associated with choice of mastectomy versus BCS.

Methods:
As a quality improvement study, we conducted a retrospective review of all early-stage (0, I, II) female breast cancer patients identified in the tumor registry between 2006-2015 at one Northeastern VA to determine rates of mastectomy and BCS. Through chart review, we examined potential determinants of BCS including age, stage, distance from treating VA facility, genetic testing, contralateral prophylactic mastectomy, and reconstructive surgery. History of MST was documented through chart review. Analyses were performed using unpaired t-test for age and distance from treatment facility and Fisher's exact test for significance comparing history of MST between surgical groups.

Results:
70 women with early stage breast cancer were eligible for BCS. Of these, 39 underwent BCS and 31 underwent mastectomy (55% rate of BCS). Age and distance to treating VA were not significant. Women who underwent mastectomy were on average younger (p=0.21) and lived farther away (p =0.42) and were more likely to undergo genetic testing. Of the women who underwent genetic testing (10/70), none had mutations. The biggest difference seen between surgical groups was in history of MST, with women in the mastectomy group having more than twice the prevalence of MST, 58%, vs 31% in the BCS group (p = 0.0154)

<table>
<thead>
<tr>

<td>18(58%)</td>
</tr>
</tbody>
</table>

Conclusion:
These data suggest that MST is associated with choice of mastectomy over BCS. MST results in poor body image which may impact decisions about breast surgery. Trauma-informed strategies for counseling women about options for surgical management...
of early stage breast cancer may be needed to ensure that women with MST and other forms of trauma pursue evidence-based cancer treatment. Further work with a larger cohort is needed to better understand these findings.
Study result dissemination preferences of research participants in the Army of Women® program

Nicole Laurita¹, Laura Roudebush¹, Leah Eshraghi¹ and Susan Love¹. ¹Dr. Susan Love Research Foundation, Encino, CA.

Background:
The Army of Women (AOW) is a breast cancer research program of Dr. Susan Love Research Foundation (DSLRF). This initiative aims to accelerate breast cancer (BC) research by engaging and connecting the public with clinical research. To date, over 382,000 women and men, with and without BC, have registered as members. AOW members have full access to a curated repository of supported research studies and educational resources about the science of BC and the clinical research process. This highly motivated, proactive membership has donated their time, biological samples, and health data to advance studies over the last 10 years. Previous literature has demonstrated that research volunteers are less likely to participate in future studies if not informed of study results. With a membership that has volunteered to participate in over 130 studies, we sought to examine members' interest in receiving study results and preferred dissemination methods.

Methods:
An adaptive, anonymous, online survey collected data on demographics, motivations, engagement behaviors, and attitudes toward research. Participants (N=1,486 to date) were recruited via email (AOW members only) and social media (AOW members and non-members; Facebook posts and ads). Responses were analyzed to understand participant preferences in study result dissemination and outreach methods. For these analyses, the cohort was limited to AOW members who completed the survey and reported past participation in AOW-supported studies.

Results:
Of the 1,486 respondents, 527 (mean age 62.7 years, range 30-85) indicated AOW membership and reported past participation in AOW-supported studies. The majority was female (99%) and non-Hispanic white (94%). Over half (65.46%) reported a history of BC.

Of participants, 71% would like to learn about scientific results from studies that included members of the AOW. The preferred dissemination frequency and methods are monthly via email (61%) or social media (26%). Based on participants' reported social media use, dissemination through Facebook (74%) would yield the greatest reach – followed by YouTube (24%), Instagram (22%), LinkedIn (15%), Twitter (14%), and Snapchat (4%).

In addition to updates about study results, 75% of participants want to hear about publications from past AOW-supported studies. Importantly, a majority (84%) of those also want access to a brief overview and lay explanation of the publication. The preferred methods of dissemination for these publications and lay overviews are AOW newsletters (84%), a dedicated menu on the AOW website (51%), social media (29%), and blog posts on the DSLRF website (16%).

Conclusions:
As in prior literature, clinical research participants in the AOW program indicate a high preference for receiving updates and staying informed about past study results. Participants indicate that they prefer to receive these results through emailed newsletters, websites, and social media. Researchers should consider these low-cost methods as they plan for result dissemination. Our findings support that volunteers want to be informed about results of their participation. This provides a clear opportunity for researchers to keep volunteers engaged and interested in participating in future clinical research.
MBC Connect™, an open-access, patient-reported registry of de-identified data from patients living with metastatic breast cancer

Laurie Campbell¹, Kristine De La Torre¹, Clay E Williams¹², Shirley A Mertz¹³, Teri Pollastro¹, Andrea Hutton¹, Joshua Newby¹⁴, Matthew J Ellis⁵, Neil M Iyengar⁶ and Marc S Hurlbert¹⁷. ¹Metastatic Breast Cancer Alliance, New York, NY; ²Meadaptive Health, Inc., New York, NY; ³Metastatic Breast Cancer Network, Chicago, IL; ⁴Theresa’s Research Foundation, Houston, TX; ⁵Baylor College of Medicine, Houston, TX; ⁶Memorial Sloan Kettering Cancer Center, New York, NY and ⁷Breast Cancer Research Foundation (BCRF), New York, NY.

Metastatic breast cancer (MBC) remains an incurable disease and is the cause of nearly all deaths from breast cancer. Several barriers prevent efficient research into various questions about living with MBC. A key unmet need is a national database for MBC patient-reported outcomes, which does not exist anywhere in the world. Furthermore, compartmentalized data prevents broad collaborative efforts. Treatment patterns and responses, survival times, and metastatic patterns are not documented systematically and remain unavailable. Large-scale data extraction is challenging, and expensive, and electronic medical records do not provide information regarding patient experiences. **Methods:** MBC Connect™ was created to help overcome these barriers. MBC Connect, which is sponsored by the Metastatic Breast Cancer Alliance, is a multi-national registry of participant reported information about their experience of MBC. MBC Connect allows MBC patients to voluntarily provide information about their disease, treatment outcomes, and experience of living with their disease so that researchers can gain insight into unmet needs in MBC. MBC Connect has three main goals: 1. Establish an interactive registry of patient-entered, de-identified data for MBC. 2. Create an open-access portal for researchers to study these data. 3. Create a connection between investigators of clinical trials and clinical research studies and registered users who may be interested in clinical trials. **Results:** MBC Connect collects, via the use of a mobile app (on a smartphone or tablet, iOS and Android compatible) or via a website for desktop users, participant consent, general patient characteristics and demographics, disease characteristics, genetics and tumor mutations, treatment history, quality of life data, and clinical trial experience. This information can be provided by patients living with MBC or their caregiver. The data are collected from responses to surveys and via creation of a treatment profile. The data are de-identified and made available on an open-access Researcher portal, allowing them to be used to advance multiple areas of research into MBC, including both medical treatment aspects and quality of life issues. An interactive feature of MBC Connect is that researchers may submit a request for participants to answer additional surveys. Participants may also be notified about clinical trials for which they may be eligible. In addition, participants will regularly receive “Insights,” which are engaging bytes of information related to MBC. Insights can offer general information about the disease, upcoming events, and other facts, or they can be personalized for the participant based on the information he or she has entered the registry. **Conclusions:** MBC Connect is a novel platform that aims to accelerate MBC research by providing open access to patient-reported, de-identified data about patients living with MBC. The overarching objective of this technologic initiative is to increase patient engagement with the research community.
Health-related quality of life in MONARCH 3: Abemaciclib plus an aromatase inhibitor as initial therapy in women with HR+, HER2- advanced breast cancer

Mathew Philip Goetz¹, Stephen Johnston², Miguel Martin³, Eriko Tokunaga⁴, In Hae Park⁵, Jens Huober⁶, Masakazu Toi⁷, Gregory L Price⁸, Mark Boye⁶, Li Li⁶, Tammy Forrester⁶, Jonathon Gable⁶, Gebra Cuyun Carter⁸, Anchal Sood⁹ and Angelo DiLeo¹⁰. ¹Mayo Clinic, Rochester, MN; ²Royal Marsden NHS Foundation Trust, London, United Kingdom; ³Instituto de Investigación Sanitaria Gregorio Marañon, CIBERONC, Universidad Complutense, Madrid, Spain; ⁴National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan; ⁵National Cancer Center, Goyangsi, Korea; ⁶University of Ulm, Ulm, Germany; ⁷Kyoto University Hospital, Kyoto, Japan; ⁸Eli Lilly and Company, Indianapolis, IN; ⁹Eli Lilly Services India Pvt. Ltd., Bangalore, India and ¹⁰Nuovo Ospedale di Prato S. Stefano – Istituto Toscano Tumori, Prato, Italy.

Background: In the MONARCH 3 trial, abemaciclib plus an aromatase inhibitor (AI) significantly improved progression free survival and overall response rate with a generally tolerable safety profile compared to placebo plus AI. Here we report patient-reported outcomes (PRO) including health-related quality of life (Qol), functioning, and symptoms.

Methods: MONARCH 3 was a double-blind, randomized phase III study of abemaciclib or placebo plus an AI in 493 post-menopausal women with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer with no prior systemic therapy in the advanced setting. Two European Organization for Research and Treatment of Cancer (EORTC) questionnaires were included: Quality of Life Questionnaire (QLQ)-Core 30 (C30) and the EORTC QLQ-Breast 23 (BR23) that were assessed at baseline, every 2 cycles through cycle 19, then every 3 cycles until treatment discontinuation, and at short-term follow up. Higher scores on functional and health status/QoL outcomes indicate higher/better levels of functioning or health; conversely higher scores on symptom outcomes indicate higher/worse levels of symptom burden. Between-arm comparisons of change from baseline were conducted using mixed model methods. Statistical significance was set at 0.05 and clinical meaningfulness was set at ≥10 points on a 0-100 scale¹.

Results: PRO completion rates were >91% through cycle 19; duration of treatment was longer for abemaciclib plus AI patients (median number of cycles 19 vs.15). Compared to the placebo arm, diarrhea PRO scores in the abemaciclib arm showed a clinically (18.68 points) and statistically significant (p<0.001) increase/worsening. By-cycle analysis showed group mean diarrhea scores returned to near-baseline levels post-therapy. Other symptom PROs showed statistically significant (<0.05) but not clinically meaningful differences; fatigue (4.96; p=0.004), systemic therapy side effects (4.48, p<0.001), appetite loss (4.03; p=0.034), and nausea/vomiting (2.77; p=0.013). These results were consistent with the investigator-reported treatment emergent adverse events (TEAEs). Several non-symptom results were also statistically significant but not clinically meaningful including global health/health status (-4.36; p=0.003), role function (-4.25; p=0.025), social function (-3.41, p=0.047), and body image (-5.11, p=0.009). No statistically significant between-treatment differences were observed for physical, emotional, and cognitive functioning or for symptoms of pain, dyspnea, insomnia, constipation, or financial difficulties.

Conclusions: The addition of abemaciclib to an AI resulted in clinically and statistically significant changes in diarrhea without clinically meaningful differences in other symptom scores. Increased GI-related symptoms were consistent with the manageable, reversible AE profile; the highest symptom burden was reported during early visits. No clinically meaningful differences in global health status or functional scores were observed.

ClinicalTrials.gov: NCT02246621

Fertility preservation in young breast cancer patients: Real life data on 1390 patients treated in the Institut Curie

Anne-Sophie Hamy-Petit¹, Aullène Toussaint¹, Camille Sautter¹, Florence Coussy¹, Anne Donnadieu¹, Roman Rouzier¹, Claire Saule¹, Sophie Frank¹, Anika Bensen¹, Michael Grynberg², Valerie Scarabin-Carre², Pietro Santulli³, Thomas Balezeau¹, Julien Guerin¹, Emmanuel Reyrat⁴, Christophe Jamain⁴, Alice Hours¹, Anne Lecourt¹ and Fabien Reyal¹. ¹Curie Institute, Paris, France; ²Antoine Beclere Hospital, Clamart, France; ³Port Royal Hospital, Paris, France and ⁴Unicancer Federation, Paris, France.

Introduction: Adverse effects of chemotherapy on fertility are a critical concern for young breast cancer (BC) patients. Fertility preservation (FP) is currently offered to BC patients, though literature data concerning reproductive outcomes are scarce. Also, very few data are available on whether these procedures are associated with delay to treatment, or whether they impact oncologic outcomes. The objective of our study is to evaluate: (i) efficacy of FP procedures in terms of stored material and pregnancy rates, (ii) safety regarding time from BC diagnosis to chemotherapy, and oncologic outcomes in a large real-life cohort of BC patients.

Methods: We retrospectively analyzed medical charts of all consecutive patients aged between 18 and 43 diagnosed with invasive BC between 01/01/2011 and 30/09/2017 and treated with chemotherapy at Institut Curie (Paris and Saint Cloud). Baseline factors (antral follicle count (AFC), AMH), details on fertility preservation procedures, and results (number of frozen oocytes and embryos) were retrieved in 3 academic hospitals (Jean Verdier, Antoine Béclère and Cochin). All medical charts were reviewed in March 2018 to assess time from diagnosis to surgery / chemotherapy, pregnancy outcomes, recurrence and survival. We compared time from first consultation to start of chemotherapy (time diagnosis-to-CT) in case of neoadjuvant chemotherapy (NAC between patients who had or who did not have PF.

Results: On 1,390 patients identified, 622 had NAC, 768 had adjuvant CT. Median age at diagnosis was 38.8 y.o. 136 were BRCA mutated.

- 264 patients (19%) underwent a FP procedure: In Vitro Maturation (IVM) (58%, n=154); ovarian stimulation protocol (STIM) (31%, n=82); others (10%, n=28). The mean number of oocytes preserved was 5 [0-36] and was not different between IMV and STIM.

- Delays from diagnosis to CT were not different in patients who had FP than those who did not, neither in patients with NAC (no FP: 24.1 days VS FP: 22.8, p=0.24) nor in patients with adjuvant CT (no FP: 70.6 days VS FP : 66.8, p=0.11).

- 39 patients had at least one pregnancy: 28 spontaneous, 6 without information, and 5 from oocyte/embryo donation. The pregnancy rate was higher in patients in FP group (n=16 ; 6%) than in no FP group (n=23 ; 2%). 3 reused material : 2 without pregnancy and one had a miscarriage.

- About oncologic outcomes, 90 patients underwent relapse (6,4%), and this rate was not significantly different in the 2 groups (n=12, 4,5% VS n=78, 6,9%).

- Patients with BRCA mutation (BRCAm) had lower AMH (2.9 VS 4.1 ng/mL ; p = 0.03) and antral follicle count (17.6 VS 24 ; p = 0.01). However, there was no difference on the stored material, and pregnancy rate was higher than in patients with no mutation or unknown status (7.6 VS 2.6% ; p = 0.01).

Conclusion: Pregnancy rate was higher in patients with FP, however majority of pregnancies was spontaneous, and no live birth was observed after material reuse. FP procedures were not associated with delay to treatment. Though bias cannot be excluded, preliminary data do not show an adverse impact of FP on oncologic outcome. Further follow-up is needed.
The impact of ductal carcinoma in situ of the breast on health services utilization and general health and well-being of women

Eileen Rakovitch\textsuperscript{1,2}, Rinku Sutradhar\textsuperscript{2}, Limei Zhou\textsuperscript{2}, Sharon Nofech-Mozes\textsuperscript{1}, Wedad Hanna\textsuperscript{1} and Lawrence Paszat\textsuperscript{1,2}. \textsuperscript{1}Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada and \textsuperscript{2}Institute for Clinical Evaluative Sciences, Toronto, ON, Canada.

\textbf{Background:} The impact of DCIS diagnosis on the development of significant anxiety and depression and on the utilization of breast imaging and breast biopsy procedures, which may reflect fears of breast cancer recurrence, is unknown. We established a population cohort of women with DCIS and examined the impact of the DCIS diagnosis on health services utilization (physician, emergency room visits) before and after DCIS, including those related to anxiety or depression, and all breast-related interventions, compared to similar women without DCIS.

\textbf{Methods:} From hospital claims we identified a population-based cohort of women with a first diagnosis of DCIS between 2010-2015. Cases with prior history of cancer were excluded. We identified treatment (mastectomy, breast-conserving surgery (BCS) +/- radiation therapy (RT) by linkage of administrative databases. Using DCIS diagnosis date for each case, we matched 5 unaffected controls (with no history of DCIS) by age, mammography history, socioeconomic status, and comorbidity at same date. For all cases and controls we extracted the following from physician billing claims: breast imaging (mammography, ultrasound, MRI), breast biopsies, breast surgery, all physician visits, and all hospital claims (including those with a diagnosis of anxiety or depression), for five years prior to and following the index date. We excluded claims from the year prior to and subsequent to the index date to remove the effect of services utilization surrounding the diagnosis and management of the index DCIS lesion. We then computed the rate of each service per 100 person-years for 5 years before and after the index date. Cases who developed local recurrence (LR) (and their matched controls) were censored 3 months prior to LR date. We used negative binomial regression to test differences in rates of service utilization before and after DCIS diagnosis and between cases and unaffected controls.

\textbf{Results:} The cohort includes 4,977 women treated for DCIS were identified, each matched to 5 controls. 911/4,977 (18.3\%) of cases were < 50 years old at diagnosis; 1,006/4,977 (20.2\%) were treated by BCS alone, 2,995/4,977 (60.2\%) by BCS+RT, and 976 (19.6\%) by mastectomy. For cases diagnosed with visits with a breast diagnosis code, utilization of breast imaging procedures and the use of breast surgery was significantly greater relative to unaffected controls irrespective of age at diagnosis and treatment (all p values <0.0001). Primary care visits were higher among cases (RR=1.10 (95\% CI 1.06, 1.14), p<0.0001), including those with a breast diagnosis code (RR=3.69 (95\%CI 3.29, 4.14)). However, there was no increase in relative rates of physician or hospital visits for anxiety or depression (RR 1.13 (95\% CI 0.97, 1.32 p=0.11), psychiatry visits (RR 1.07 (95\% CI 0.82, 1.40) p=0.6), non-breast surgical procedures (RR 1.10 (95\% CI 0.88, 1.37) p=0.4), or emergency department visits (unrelated to breast) in cases with DCIS compared to unaffected controls.

\textbf{Conclusion:} DCIS is associated with more visits and procedures related to the breast compared to women without a diagnosis of DCIS but overall health services utilization and visits related to anxiety and depression were not increased.
A self-administered geriatric assessment tool for Spanish-speaking older women with breast cancer

Enrique Soto-Perez-de-Celis1,2, Jessica Vazquez1, Heeyoung Kim1, Can-Lan Sun1, George Somlo1, Yuan Yuan1, James R Waisman1, Joanne E Mortimer1, Laura Kruper1, Lesley Taylor1, Niki H Patel1, Jeanine Moreno1, Kemeberly Charles1, Elsa Roberts1, Carolina Uranga1, Abraham Levi1, Vani Katheria1, Irene Paredero-Perez1,2, Dale Mitani1 and Arti Hurria1. 1City of Hope, Duarte, CA; 2Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico and 3Hospital Universitario Doctor Peset, Valencia, Spain.

Background: Almost a quarter of older adults in the United States will identify themselves as Hispanic/Latino by 2060. Our group has previously developed and validated a self-administered geriatric assessment tool which can be used to identify functional, psychological, social and cognitive impairments among older patients with various types of cancer. Among English-speaking older adults, completing this tool using paper/pencil or a tablet takes a median of 15-21 minutes (min), with < 10% needing assistance to answer it (Hurria, JOP 2016). However, the utilization of this tool among Spanish-speaking older adults has not been tested. We assessed the feasibility of administering a translated and validated Spanish version of our geriatric assessment tool for older Hispanic women with breast cancer, and identified their preferred format (tablet or paper/pencil).

Methods: Spanish-speaking women aged ≥ 65 years with a diagnosis of breast cancer completed the geriatric assessment twice on the same day. Patients were randomized into 3 groups: paper/pencil twice; tablet and paper/pencil in random order; and tablet twice. We assessed the proportion of patients requiring assistance to complete the geriatric assessment, the time needed to complete it, and the proportion of patients who thought the geriatric assessment was difficult/very difficult.

Results: 140 older women with breast cancer completed the geriatric assessment twice and were evaluable. Mean age was 71.6 years (SD 5.8), 53% had ≤ 8th grade education, 43% were married, 45% were retired, 32% were homemakers, and 6% were employed. The participants came from 13 different Spanish-speaking countries, although 70% were born in Mexico. For 90%, Spanish was their primary language, and 75% spoke only in Spanish at home. Regarding computer skills, 64% of the patients said they had none. 39% (n = 54) were unable to complete the geriatric assessment on their own; mean time to complete the geriatric assessment was 29 min (range 8-90); and 28% (n = 39) thought the geriatric assessment was difficult/very difficult. The most common reasons for needing assistance were difficulty understanding questions (39%) and visual problems (31%). Patients with ≤ 8th grade education took longer to complete the geriatric assessment (mean 37.2 vs 29.4 min, p < 0.01), and more often needed help completing the assessment (51% vs 19%, p < 0.01) than those with ≥9th grade education. 53% of the participants preferred using a tablet to answer the geriatric assessment, while 47% preferred paper/pencil.

Conclusions: A substantial proportion of Spanish-speaking older women with breast cancer required assistance to complete our self-administered geriatric assessment tool. This may be a consequence of the low educational level we found among this patient population. Tailoring assessments for diverse populations with particular attention to educational level is needed in multicultural settings.
Radiation oncologists' views on breast radiation therapy guidelines: Utilizing an online Q&A platform to assess current views on whole breast radiation therapy

Lindsay Burt¹, Bruce G Haffty², Benjamin Smith³ and Nadine Housri⁴.⁵. ¹University of Utah Huntsman Cancer Institute, Salt Lake City, UT; ²Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; ³MD Anderson Cancer Center, Houston, TX; ⁴theMednet.org, New York, NY and ⁵Yale School of Medicine, New Haven, CT.

Introduction: Adherence to clinical practice guidelines (CPGs) has long been a challenge due to a lack of knowledge about CPGs and the fact that CPGs may not be practical in the context of a particular patient's situation. Poor adherence to the 2011 American Society for Radiation Oncology (ASTRO) evidence-based guideline on whole breast irradiation has been reported, especially for hypofractionated whole breast radiotherapy (HBRT). In 2018, updated ASTRO guidelines were published. We utilized theMednet, an online Q&A platform of over 3,600 US community and academic radiation oncologists (ROs), to assess current views regarding whole breast RT and evaluate relationships between the strength of guideline recommendation statements and ROs views on treatment choices.

Methods: We identified 11 questions previously asked by community ROs on theMednet that were not addressed in the 2011 ASTRO whole breast irradiation guideline. Questions were originally asked between 10/27/2014 and 5/2/2017. These questions were sent to a senior author of the 2018 guidelines to post an updated response on theMednet, citing the guidelines and degree of consensus. A link to view the full guidelines was provided. New answers citing the guidelines were disseminated in 3 biweekly newsletters between 3/16/2018 and 5/1/2018, along with polls to survey radiation oncologists participating in theMednet.

Results: A total of 792 ROs responded to polls, of whom 523 were community ROs, 129 were academic ROs, and 93 were residents. Of the 11 questions, 10 pertained to WBRT and 1 pertained to conventional dose fractionation. For each question, the answer choice receiving the majority of the votes aligned with the 2018 guideline. Of the 5 questions which referenced a conditional recommendation in the 2018 guideline, the majority vote ranged from 54% to 87%; whereas, of the 6 questions which referenced a strong recommendation in the 2018 guideline, the majority vote from 62% to 97%. The strongest consensus was for HBRT to be used regardless of histology (97%), followed by molecular subtype (90%), grade (89%), and concurrent use of trastuzumab (87%). The least consensus was for age at which HBRT should be offered, with only 54% of respondents agreeing with the guideline consensus that HBRT should be offered regardless of age. When comparing academic and community ROs, 73% of academic ROs do not specify an age threshold for offering HBRT, compared to 47% of community ROs (P<0.0240). Regarding boost dose-fractionation, 83% of academic ROs prefer a 10 Gy in 4 fractions while 54% of community ROs prefer 10 Gy in 5 fractions and 41% prefer 10 Gy in 4 fractions (P=0.1495). Responses were similar between academic and community ROs for all other questions.

Conclusion: Utilizing an online platform, theMednet, we were able to assess current views of management of whole breast radiation therapy among participating ROs. The majority of ROs agree with the major recommendations from this guideline, with practice variation greater in areas with weaker underlying evidence.
Twitter chats: Utilizing an innovative technology platform to offer education and tools to people with breast cancer

Janine E Guglielmino¹, Catherine L Ormerod¹, Amy B Grillo¹ and Sharon A Sood¹. ¹Living Beyond Breast Cancer, Bala Cynwyd, PA.

**Background.** The use of social media for health information and peer support has grown significantly over time. According a 2015 study from the Pew Research Center, 65 percent of U.S. adults utilize social media, up from 7 percent a decade earlier. A 2014 study reported 72 percent of adult internet users search online for health information, often focused on specific diseases or treatments, with 16 percent seeking others with similar health concerns. Twitter, a popular social media platform for information- and support-seekers, grew from 54 million monthly active users in 2010 to approximately 241 million in 2013. To address the growing use of Twitter as an information and support portal, Living Beyond Breast Cancer (LBBC) decided to pilot a Twitter chat in 2014. The goals for the chat were to: (1) increase understanding of a breast cancer concern; (2) connect impacted individuals to one another in a supportive and safe online space; (3) offer practical resources for further exploration; and (4) increase LBBC's reach online among users interested in breast cancer.

**Methods.** LBBC staff researched best practices for Twitter chats. The topic of triple-negative breast cancer (TNBC) was chosen for LBBC's pilot program to coincide with Triple Negative Breast Cancer Awareness Day. The staff developed 7 questions and 10 alternates to deliver over 60 minutes. Using publicly available data from Symplur, hashtags were considered and developed. A panel was recruited of one medical oncologist, two advocates, and two women with TNBC. Panelists were encouraged to prepare Tweets in advance and, during the chat, to use assigned hashtags, correct medical inaccuracies, and attend to emotional concerns among chat participants. LBBC staff developed resource-rich tweets. The program was promoted over social media channels. At the end of the chat, participants were offered an incentivized opportunity to evaluate the program via a URL link to LBBC's existing survey instrument.

**Results.** Using the #TNBCchat hashtag, the March 3, 2014, program and activity the next week produced 234 tweets from 127 contributors, reaching 198,985 accounts. Participants wrote 118 tweet replies and retweeted 291 comments. Questions covered the definition of and treatments for TNBC, differences between metastatic and early-stage disease, unique emotional concerns, and methods to reduce recurrence risk. The three most popular tweets promoted the program, introduced panelists, and shared resources about PARP inhibitors. Encouraged by the pilot program's reach and results, LBBC has delivered 20 Twitter chats as of June 2018. Topics have included nutrition, parenting, caregiving, and breast reconstruction. Over time, LBBC staff has refined the program model with the goals of increasing engagement, delivering more useful content, and driving users toward the evaluation.

**Conclusions.** Twitter chats allow nonprofit organizations to inexpensively utilize innovative technology to provide educational information to and foster a community of support among people impacted by breast cancer. By utilizing core organizational principles of appropriate program delivery, LBBC delivers practical content that may improve the quality of life of users in distant locations.
BACKGROUND: BREAST-Q is a patient-reported outcome (PRO) that has been designed to evaluate perception outcomes among women undergoing different types of breast surgery, the modules include evaluation for mastectomy, breast reconstruction, augmentation, reduction/mastopexy and breast-conserving therapy.

OBJECTIVES: Generate a translated version that is conceptually equivalent to the original version and to validate for Mexican population.

METHODS: A linguistic and psychometric validation was performed in 494 women. We carry out pre and postoperative test. Reliability and internal consistency were performed by Cronbach's alpha and intraclass correlation coefficient (ICC).

RESULTS: The results of patient testing, number of participants, acceptability and reliability are shown in table 1

We report the low and the high value between all sub scales, per questionnaires.

. The average scores were in all cases >0.80.

The internal consistency and reproducibility support the reliability of the instrument; all of the scores were acceptable.

DISCUSSION: The importance of measurements quality of life in patient whit cancer, become an essential end-point, we need validated tools that help us improve our performance in different methods of treatments.

Is the first validation study of an instrument that measures the impact of surgical treatment on the quality of life of breast cancer patients in Mexico, our results support the equivalent Spanish version for Mexican population. Breast-Q will provide valuable metrics for a surgeon team to document and measure their clinical performance and improve quality of healthcare in our Hispanic patients.

CONCLUSIONS: The Mexican Spanish version of tree Modules of Breast-Q is reliable and easy to implement in the population with breast cancer in different scenarios in México with the advantage to measure the quality of life and satisfaction on our population with a locally advanced stage that will help to improve quality of healthcare.

The high acceptability of the questionnaire demonstrate that the version is well accepted for our population so we will include a
significant number of patient in our country; therefore, more hospital centers will be invited to participate for further studies that allow us to evaluate the population in Latin America and thus compare our results.
Using continuing professional development (CPD) as an investigative tool to improve clinical practice and interdisciplinary team treatment

Kathleen Harnden¹ and Danubia Hester². ¹Inova Schar Cancer Institute, Fairfax, VA and ²Inova Fairfax Medical Campus, Falls Church, VA.

Background:
Continued and rapid evolution of diagnosis and staging methods along with the development of new treatments has changed the decision-making process for cancer patients into a more complex task. In breast cancer, quality measures related to sentinel lymph node biopsy (SLNB), axillary dissection (AD), HER2 testing and use of HER2-targeted therapy, provide parameters for assessing care quality. We assessed the influence of quality improvement education (QIE) on alignment with BC quality indicators.

Methods:
39 members of the interprofessional team at Inova (an integrated care network of 5 hospitals) participated in the QIE components. For a baseline Inova provided deidentified electronic medical records (EMR) data that included a total of 67 breast cancer patients treated between 12/1/16 – 2/28/17. The patients diagnosed with HER2+ breast cancer records were retrospectively reviewed for adherence to quality measures pertaining to HER2 testing, SLNB, AD, and treatment. Follow-up reviews were completed 6 months after the launch of the online component, which included 142 patients.

Results:
Patient and disease characteristics were generally similar across the 2 cohorts. At baseline, treatment selection for patients with advanced stage cancer was consistent. The original goal of the activity was to assess adherence to quality measures in breast cancer treatment, in our assessment stage the team discovered potential undersampling of sentinel lymph nodes in patients who underwent neoadjuvant chemotherapy for clinically node-positive, with 3 of 8 patients (37.5%) having only 1 or 2 lymph nodes sampled. The educational programming improved recognition of the risk of false negative rates of sampling under 2 lymph nodes in this setting. In addition, the Inova team recommended that the triage protocol be changed to include the medical oncologist earlier in the treatment decision making process in tandem with the surgeon. In the post-program patient data, 26 patients with clinically N1/N2 disease had neoadjuvant therapy and a SLN biopsy. Of these, 3 (11.5%) had only 1 lymph node sampled, suggesting an increased adherence to recommended sampling.

The educational program also improved participant knowledge of the phase III APHINITY trial efficacy findings, which was consistent with an increase in the use of pertuzumab-containing adjuvant therapy for early breast cancer (use of TCHP, 0% vs 46% in the pre-program and post-program charts, respectively). In addition, participants in the educational programming increased awareness of the need for reflex testing in the event of an equivocal HER2 IHC result. In the post-program follow-up, no cases of equivocal HER2 IHC staining lacked reflex testing with FISH.

Taken together, these findings are consistent with practice change following interventional medical education for incorporating best practices and emerging clinical data in the management of HER2-positive breast cancer.
What research questions matters most to patients? Final results of the metastatic breast cancer priority setting partnership

Nancy A Nixon1, Christine Simmons2, Julie Lemieux3 and Sunil Verma1. 1Tom Baker Cancer Centre, Calgary, AB, Canada; 2British Columbia Cancer Agency, Vancouver, BC, Canada and 3Chu de Quebec, Quebec, Canada.

Background: Research is fundamental to the management of cancer, however many studies are primarily researcher or industry led, with minimal input and involvement from the people most affected by the outcomes- the patients and caregivers. The James Lind Alliance (JLA) is a not for profit initiative that brings patients, caregivers and clinicians together in priority setting partnerships (PSPs) to determine key priorities in research. Breast cancer remains the most common cancer among women, with an estimated third of women diagnosed developing metastatic disease. With advances in treatment, women are living longer with metastatic breast cancer (MBC), in some cases many years. Objectives: The aims of this study are to utilize the JLA approach to (1) identify the unanswered questions about treatment of MBC from patient and clinical perspectives, and (2) to prioritize those that patients and clinicians agree are the most important. Methods: Following the established JLA approach, MBC patients, caregivers, and health professionals were surveyed to elicit their questions pertaining to MBC. Research questions were generated from the survey responses, and following literature review that the questions were currently not completely answered, an interim prioritization survey was conducted to identify a shortlist of questions to take to a final consensus meeting. Results: One thousand, one-hundred and ninety-four responses were collected from 668 individuals (49% patients; 13% physicians; 9% caregivers; 4% allied health care professionals; 2% patient organization representatives; 23% other), which were refined into 62 unique unanswered research questions. The interim prioritization survey was completed by 174 individuals, and the top 27 questions were taken to a final meeting where MBC patients, caregivers, and health care professionals prioritized all the questions, and reached consensus on the top 10

Conclusion: The top 10 questions cover a wide range of research questions, identified by valuable stakeholders as being priorities. These priorities can be used to fund and inform future MBC research.
Is pregnancy testing during chemotherapy standardized?

Natalie Berger¹, Katherine Fitzpatrick¹ and Paula Klein¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY.

The initiative to improve awareness about the risks of infertility for premenopausal patients receiving chemotherapy has improved significantly over time. While the risks for infertility are high, there is still a small risk of pregnancy during chemotherapy. The incidence of cancer diagnosed during pregnancy is 0.1-0.2%. The incidence of women who become pregnant while on chemotherapy is less clear but does occur. Amenorrhea commonly occurs during chemotherapy but this does not necessarily correlate with lack of ovarian function. Treating a patient with an unidentified pregnancy is an adverse event which must be avoided given the high risk it poses to the fetus, especially during the first trimester. Pregnancy testing prior to the initiation of chemotherapy is recommended by the NCCN and ASCO. However, recommendations on how to monitor for pregnancy after an initial screen are inconsistent and lack standardization. Formal guidelines and policies are needed to prevent and/or identify pregnancies while on chemotherapy.

We surveyed five breast medical oncologists and six infusion nurses at a busy urban breast center to determine their baseline practices in regards to pregnancy counseling and testing. Of physicians and nurses surveyed, 40% (2/5) and 33% (2/6) respectively have diagnosed a pregnancy while on chemotherapy. When surveyed about counseling patients on the risks of pregnancy, 80% of physicians counsel patients prior to initiation of chemotherapy, but one physician and one infusion nurse said they do not counsel patients about the risk of pregnancy at any time but do discuss the risks of infertility. All physicians surveyed check a pregnancy test prior to the initiation of chemotherapy, but 60% check urine and 40% check serum. Thereafter 60% will check a pregnancy test after initial screen if the patient is concerned and 40% will check intermittently during chemotherapy. Of the nurses surveyed, 33% will check a pregnancy test after initial screen if the patient is concerned and 50% check intermittently during treatment. Half of the infusion nurses said they ask patients if they are concerned they may be pregnant intermittently during chemotherapy and 50% answered that they do not ask again after the initial screen. On subsequent screens the choice of urine or serum hCG testing varies and is not standardized.

These survey results demonstrate that both pregnancy counseling and pregnancy screening practices vary widely even within the same institution. A standardized approach is essential to increase awareness of pregnancy risk while on chemotherapy, improve education of this risk to patients, prevent unwanted pregnancies, and identify pregnancies as soon as possible. We have initiated a quality improvement project to check urine pregnancy tests monthly in all premenopausal patients (age <55) receiving chemotherapy for breast cancer. Based on our findings we will institute a protocol at our institution for uniform teaching on the small risk of pregnancy and uniform pregnancy testing while on chemotherapy.

Background: HER2-targeted therapies have improved survival for advanced HER2-positive breast cancers (BC), but none have been approved for tumors with low levels of HER2 expression (ie, HER2 IHC 1+ or 2+/ISH-negative). Trastuzumab deruxtecan (DS-8201a) is a novel HER2-targeted antibody-drug conjugate with a humanized HER2 antibody attached to a potent topoisomerase I inhibitor payload by a cleavable peptide-based linker, which is designed to have broad antitumor activity in HER2-expressing tumors. It has a drug-to-antibody ratio of 7 to 8, a novel linker that is stable in plasma and that is selectively cleaved by lysosomal cathepsins which are upregulated in cancer cells, and its payload has a short systemic half-life. In 2015, a phase 1 study (NCT02564900) was initiated to evaluate the safety and efficacy of DS-8201a in subjects with advanced HER2-expressing or HER2-mutated solid tumors, including HER2-low expressing BC. In this study, the overall confirmed response rate (ORR) in the evaluable subjects was 49.3% (103/209) (April 2018 data cutoff; Iwata H, et al. ASCO 2018). Expanded results from the HER2-low expressing BC subjects are presented here.

Methods: This ongoing phase 1 trial included 2 parts. The dose escalation part served to determine the dose-limiting toxicities, the maximum tolerated dose, and to select the recommended dose for expansion (RDE). The dose expansion part further evaluated the safety, tolerability, and efficacy of the DS-8201a at the RDE (5.4 and 6.4 mg/kg; q3wks) in various advanced HER2-expressing or HER2-mutated solid tumors, including heavily pretreated HER2-low BC. In this study, the overall confirmed response rate (ORR) in the evaluable subjects was 49.3% (103/209) (April 2018 data cutoff; Iwata H, et al. ASCO 2018). Expanded results from the HER2-low expressing BC subjects are presented here.

Results: At the cutoff date of 18 April 2018, data from 34 HER2-low BC subjects were collected. The median age was 55.8 (range; 33, 75) years, the median number of prior endocrine therapies was 2, and the median number of prior chemotherapies was 3. In this HER2-low BC population, most patients had hormone receptor (HR)-positive disease (85.3%; 29/34); of which 17.2% (5/29) received prior treatment with a CDK4/6 inhibitor. The confirmed ORR was 50.0% (17/34), the disease control rate was 85.3% (29/34), the median time to response was 2.8 (range; 1.2, 13.8) months, the median duration of response (DOR) was 11.0 months, and the median progression-free survival (PFS) was 12.9 months. In the subgroup with HR-positive disease, the ORR was 55.2% (16/29), the median DOR was 11.0 months, and the median PFS was 13.6 months. After exclusion of 8 HER2-low subjects who received prior HER2-targeted therapy, the ORR was 46.2% (12/26). In the overall study, among the 145 BC subjects who received ≥1 dose of DS-8201a (5.4 or 6.4 mg/kg), the most frequent grade ≥3 adverse events included anemia (14.5%), and decreased counts of neutrophils (13.8%) and white blood cells (10.3%). There were 4 fatal cases of interstitial lung disease/pneumonitis in BC subjects, including 2 fatal cases in HER2-low BC subjects.

Conclusions: In this study, DS-8201a showed substantial antitumor activity and acceptable safety in heavily pretreated HER2-low BC.

Publication Number: P6-17-03

24 months results from a double-blind, randomized phase III trial comparing the efficacy and safety of neoadjuvant then adjuvant trastuzumab and its biosimilar candidate CT-P6 in HER2 positive early breast cancer (EBC)

Background CT-P6 is a proposed biosimilar to reference trastuzumab (RTZ). A double-blind, randomized, phase III trial showed similar efficacy and safety for CT-P6 and RTZ in HER2 positive EBC (NCT02162667). The primary endpoint, pathological complete response rate was within the predefined margin to demonstrate similarity (Lancet Oncol 2017). Safety and efficacy at 1 year (ESMO 2017), and cardiac toxicity at a median of 19 months (SABCS 2017) were similar between the two treatment groups. Here we report updated disease-free survival (DFS), overall survival (OS) and cardiac toxicity data with a median follow-up of 2 years.

Methods A total of 549 patients with HER2 positive EBC were randomized to receive CT-P6 (n=271) or RTZ (n=278) in combination with docetaxel (Cycles 1-4) and 5-fluorouracil, epirubicin and cyclophosphamide (Cycles 5-8). CT-P6 or RTZ was administered at 8 mg/kg (Cycle 1 only) followed by 6 mg/kg every 3 weeks. After surgery, patients received CT-P6 or RTZ monotherapy then entered the follow-up period up to 3 year of last patient enrollment. Time to event analyses were performed using Cox regression and Kaplan-Meier methods.

Results A total of 528 patients (259/271 in CT-P6 and 269/278 in RTZ) entered the follow-up period after completing therapy. The median follow-up duration was over 27 months. The number of DFS events (32 [12.4%] in CT-P6 and 26 [10.0%] in RTZ) and OS events (14 [5.2%] in CT-P6 and 12 [4.3%] in RTZ) were comparable in the ITT set. Additionally, DFS and OS were similar between CT-P6 group and RTZ group in both the per-protocol set (PPS) and the ITT set. In the ITT set, the proportion of 2-year DFS (95% CI) was 86% (80% – 90%) in CT-P6 and 90% (85% – 93%) in RTZ. The proportion of 2-year OS was 97% (93% – 98%) in CT-P6 and 98% (96% – 99%) in RTZ. Median DFS and OS have not been reached. After 1-year treatment, no new cases of heart failure were reported during the follow-up period. Left ventricular ejection fraction (LVEF) was similar in both groups (mean LVEF, more than 60%).

Conclusions The efficacy and cardiac toxicity profile between CT-P6 and RTZ in EBC patients were consistent with published
data. Time to event analyses as secondary efficacy endpoints supported the similarity for the two study drugs. CT-P6 was consistently well tolerated with a similar cardiotoxicity profile to that of RTZ through long duration of follow-up.
3-year relapse-free survival of stage II-III HER2-neu positive breast cancer treated with pertuzumab and trastuzumab-containing neoadjuvant therapy compared to trastuzumab-containing therapy

Rashmi K Murthy¹, Akshara S Raghavendra¹, Kenneth R Hess¹, Carlos H Barcenas¹, Bora Lim¹, Stacy L Moulder¹, Sharon H Giordano¹, Elizabeth A Mittendorf², Alastair Thompson¹, Naoto T Ueno¹, Vicente Valero¹, Jennifer K Litton¹, Debu Tripathy¹ and Mariana Chavez-Macgregor¹. ¹University of Texas MD Anderson Cancer Center, Houston, TX and ²Dana Farber/Brigham and Women's Cancer Center, Boston, MA.

Background: Pertuzumab (P) in combination with trastuzumab (H) based chemotherapy is FDA-approved as a standard neoadjuvant treatment for patients with clinical stage II-III HER2-positive (HER2+) breast cancer (BC). The goal of this study was to evaluate the pathologic complete response (pCR) rate for neoadjuvant HP-containing regimens compared to H-containing regimens and report the 3-year relapse-free survival (RFS) for patients who had a pCR compared to those with residual disease (RD).

Methods: All patients with stage II-III non-inflammatory HER2+ BC who received neoadjuvant H-containing or HP-containing therapy and underwent definitive breast and axillary surgery were identified from 2005 to 2016 through an institutional database. Medical records were examined for patient demographics, breast cancer stage, pathology results, surgical outcomes, and treatment details. pCR was defined as ypT0/is, ypN0. RFS was defined as the interval from surgery to date of last followup or death from any cause. Descriptive statistics, Cox proportional hazards, and Kaplan-Meier estimates were used for statistical analysis.

Results: Patient characteristics and results by pCR or RD status are shown in the table below. The median age was 51 (22-84) years for the HP group and 50 (21-87) years for the H group. The median follow-up time was 1.9 (0-4.2) years for the HP group and 5.3 (0.1-12) years for the H group. For the HP group, the 3-year RFS was 98% (95% CI: 95, 100) for the pCR group and 90% (95% CI: 83, 97) for the RD group; HR 0.17 (0.04, 0.82), p=0.012. For the H group, the 3-year RFS was 91% (95% CI: 88,94) for the pCR group and 75% (95% CI: 71-79) for the RD group; HR 0.31 (0.22, 0.44), p<0.0001. Among the 520 patients who achieved pCR and the 502 patients who had RD, the effect of HP vs. H was statistically significant (pCR: HR 0.24 (0.06, 1.00); p=0.015) (no pCR: HR 0.46 (0.22, 0.94); p=0.017).

Conclusion: Patients who achieve pCR have an improved 3-year RFS compared to patients who have RD. Treatment with HP-containing neoadjuvant regimens is associated with a high 3-year RFS.

¹1 patient in the HP pCR group had nuclear grade 1; 2 patients in the HP RD group had nuclear grade 1 tumors ²2 patients received adjuvant TDM-1 on the NSABP B50 protocol
Independent validation of a combined biomarker based on the PAM50 HER2-enriched subtype and ERBB2 mRNA levels following HER2 blockade without chemotherapy in the PerELISA phase II trial

Aleix Prat¹,², Gaia Griguolo²,³, Maria Vittoria Dieci³,⁴, Giancarlo Bisagni⁵, Antonio Frassoldati⁶, Giulia V Bianchi⁷, Tomas Pascual², Laia Pare², Patricia Galvan², Loredana Urso⁴, Pierfranco Conte³,⁴ and Valentina Guarneri³,⁴. ¹Hospital Clínic de Barcelona, University of Barcelona, Barcelona, Spain; ²Hospital Clinic de Barcelona, Translational Genomics and Targeted Therapeutics in Solid Tumours Lab (IDIBAPS), Barcelona, Spain; ³Istituto Oncologico Veneto IRCCS, Padova, Italy; ⁴University of Padova, Padova, Italy; ⁵Oncology Unit, IRCCS Arcispedale Santa Maria Nuova, Reggio Emilia, Italy; ⁶S Anna University Hospital, Ferrara, Italy and ⁷Medical Oncology Unit 1, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy.

Background: A combined biomarker based on HER2-enriched subtype (HER2-E) and ERBB2 mRNA predicts response and survival in HER2+ breast cancer following trastuzumab +/- lapatinib in the absence of chemotherapy (Prat et al. ASCO 2018). Here, we tested the ability of the combined biomarker to predict pathological complete response (pCR) following neoadjuvant trastuzumab, pertuzumab and endocrine therapy.

Methods: RNA from 40 baseline tumor samples from the phase II PerELISA trial were evaluated. PerELISA evaluated the efficacy of a de-escalated, chemotherapy-free neoadjuvant regimen based on dual HER2 blockade with trastuzumab and pertuzumab in combination with letrozole in HER2+/hormone receptor-positive breast cancer selected on the basis of Ki67 response after short course letrozole-alone (Guarneri ASCO 2018). Ki67 response was defined by protocol as relative Ki67 reduction ≥20% from baseline at day 14. Gene-expression was measured using the nCounter platform. Intrinsic subtypes and ERBB2 levels were determined by the PAM50 gene expression predictor. A pre-specified ERBB2 cutoff was determined to define ERBB2-high. Univariate and multivariable logistic regression analyses were performed.

Results: The proportion of HER2-E disease within the ERBB2-high and ERBB2-low groups was 46.2% (6/13) and 18.5% (5/27), respectively. The discordance rate at the individual level was 30% (12/40). A total of 6 (15%) and 34 (85%) samples were HER2-E/ERBB2-high and others, respectively. The magnitude of Ki67 reduction of the HER2-E/ERBB2-high and others groups was 64.8% and 63.2%, respectively (p=0.88). The pCR rate of HER2-E/ERBB2-high was 66.7%. The pCR rate of the others group was 14.7%. The univariate odds ratio between HER2-E/ERBB2-high tumors and the others groups was 11.60 (95% CI 1.66-81.10; p=0.014). No other clinical-pathological variable was significantly associated with pCR.

Conclusion: The combined HER2-E/ERBB2-high biomarker can identify patients who might be good candidates to receive dual HER2 blockade alone without chemotherapy.
Characterization, monitoring and management of interstitial lung disease in patients with metastatic breast cancer: Analysis of data available from multiple studies of DS-8201a, a HER2-targeted antibody drug conjugate with a topoisomerase I inhibitor payload

**Background:** Several classes of anti-cancer agents including certain immunotherapies, systemic chemotherapies, and targeted therapies including trastuzumab and T-DM1 increase the risk of interstitial lung disease (ILD) and fatal cases have been reported. For DS-8201a, interim efficacy and safety analyses of available data established a final recommended dose of 5.4 mg/kg IV q3wk in advanced HER2-positive breast cancer (BC). Based on preliminary clinical results, ILD was identified as an important risk for DS-8201a. A robust monitoring and management plan was established across all studies and an international, independent ILD adjudication committee (AC) reviews the cases reported as ILD on an ongoing basis.

**Methods:** All subjects (sbj) who received ≥1 dose of DS-8201a across 7 ongoing studies were included in this analysis. Reported ILD (standardized MedDRA Query terms) included the terms ILD, pneumonitis, and organizing pneumonia. ILD frequencies were calculated based on investigator's assessment and after adjudication. The analysis of potential risk factors associated with ILD is ongoing.

**Results:** As of 21 June 2018, 448 sbj received ≥1 dose of DS-8201a across 7 ongoing studies were included in this analysis. Reported ILD (standardized MedDRA Query terms) included the terms ILD, pneumonitis, and organizing pneumonia. ILD frequencies were calculated based on investigator's assessment and after adjudication. The analysis of potential risk factors associated with ILD is ongoing.

| Grade | BC, 5.4 mg/kg (N=111)         | 1              | 2              | 0              | 0              | 1              | 4              |
For adjudicated drug-related ILD cases, the median time to onset was 159 (range; 46-591) days from the time of first dose. **Conclusions:** These analyses confirm that ILD is an important identified risk for DS-8201a. Further analyses are ongoing to better understand the potential risk factors associated with the incidence of on-treatment ILD. When ILD is suspected, early diagnosis through appropriate imaging, laboratory tests, and pulmonary consultation as well as prompt management with steroids are recommended.
Gene signatures and subtype changes during HER2 dual blockade in PAM50 HER2-enriched HER2-positive breast cancer

Fara Brasó-Maristany1, Gaia Griguolo1,2, Antonio Llombart-Cussac3, Tomás Pascual1,4, Laia Paré1,4, Begoña Bermejo5, Mafalda Oliveira6, Serafín Morales7, Noelia Martínez8, María Vidal9, Sonía Pernas9, Rafael Lopez10, Montse Muñoz1, Patricia Galvan1, Isabel Garau11, Luis Manso12, Jesús Alarcón13, Eduardo Martínez14, Patricia Villagrasa1, Javier Cortés13 and Aleix Prat1,4. 1Hospital Clinic de Barcelona / IDIBAPS, Barcelona, Spain; 2University of Padova, Padova, Italy; 3Hospital Universitario Arnau de Vilanova de Valencia, Valencia, Spain; 4SOLTI Breast Cancer Research Group, Barcelona, Spain; 5Hospital Clínico Universitario de Valencia / INCLIVA / CIBERONC, Valencia, Spain; 6Vall d’Hebrón University Hospital, Barcelona, Spain; 7Hospital Universitario Arnau de Vilanova de Lleida, Lleida, Spain; 8Hospital Universitario Ramón y Cajal, Madrid, Spain; 9Institut Català d’Oncologia, Hospital del Llobregat, Spain; 10Hospital Clínico Universitario de Santiago / CIBERONC, Santiago de Compostela, Spain; 11Hospital Son Llàtzer, Palma de Mallorca, Spain; 12Hospital Universitario 12 de Octubre, Madrid, Spain; 13Hospital Universitario Son Espases, Palma de Mallorca, Spain and 14Consortio Hospitalario Provincial de Castellón, Castellón de la Plana, Spain.

**Background:** HER2-positive (HER2+) breast cancer (BC) is composed of 4 molecular subtypes: Luminal A and B, HER2-enriched (HER2-E) and Basal-like. Among them, the HER2-E is highly sensitive to anti-HER2 treatment. However, ~60% of HER2-E tumors do not achieve a pathological complete response (pCR) following neoadjuvant dual HER2 blockade without chemotherapy. Here, we aimed to better understand the molecular changes of the HER2-E subtype during anti-HER2 treatment.

**Methods:** Gene expression was evaluated in 101 patients with HER2-E tumors from the PAMELA neoadjuvant phase II trial (Lancet Oncol 2017). Briefly, women with HER2+ BC were treated with lapatinib and trastuzumab (and hormonal therapy if hormone receptor [HR]-positive) for 18 weeks. The median time between the last dose of treatment and surgery was 35 days (range=213; interquartile range=16). Expression of the PAM50 genes and 6 PAM50 signatures (Luminal A, Luminal B, HER2-E, Basal-like, normal-like and the PAM50 proliferation score) were determined using the nCounter platform at baseline (n=101), after 2 weeks of treatment (n=96) and in residual tumors (non-pCR) at surgery (n=57). Same analyses were done in 2 HER2+/HER2-E cell line models (BT474 [HR+] and SKBR3 [HR-]) following in vitro treatment with trastuzumab in combination with lapatinib.

**Results:** After 2 weeks of treatment, 85.7% and 94.6% of the 56 genes/signatures were found differentially expressed (FDR<5%) in HER2-E/HR+ (n=35) and HER2-E/HR- (n=61) tumors, respectively. The two gene lists were highly correlated (correlation coefficient=0.93). Overall, a significant relative increase in Luminal A and normal-like signature scores, and a relative decrease in proliferation, HER2-E and Luminal B signature scores, were observed between baseline and week 2. Interestingly, a PAM50 subtype switch to Luminal A was observed in 31.6% and 4.8% of HER2-E/HR+ and HER2-E/HR- tumors. In BT474 and SKBR3, all genes/signatures were also found differentially expressed (FDR<5%) following 72h of dual HER2 blockade. The in vitro findings recapitulated the in vivo findings in 80-86% of the genes/signatures. Similar to tumors, a switch to a Luminal A subtype following dual HER2 blockade was observed in BT474 but not in SKBR3. Finally, 92.9% of the 56 genes/signatures were found differentially expressed (FDR<5%) in residual tumors at surgery compared to week 2. Contrary to the findings in the first 2 weeks of treatment, a general rebound effect in gene expression was observed between week 2 and surgery. Similarly, a rebound effect was observed in 60% of the genes/signatures in BT474 after removing anti-HER2 therapy for 72h, leading to a subtype switch from Luminal A back to HER2-E.

**Conclusions:** Dual HER2 blockade in the HER2-E subtype induces large biological changes that lead to a more low-proliferative Luminal A phenotype both in tumors and in vitro models, especially in HER2-E/HR+ disease. These phenotypic changes are reversible upon stopping anti-HER2 treatment. This finding supports the use of maintenance anti-HER2 treatment +/- endocrine therapy (if HR+) in advanced HER2+ BC.
Dynamics of tumor-infiltrating lymphocytes (TILs) during neoadjuvant dual HER2 blockade in HER2-positive (HER2+) breast cancer in the absence of chemotherapy

Gaia Griguolo1,2, Esther Holgado3, Javier Cortés3, Roberta Fasani4, Tomás Pascual1,5, Laia Paré1,5, Begoña Bermejo6, Mafalda Oliveira7, Serafín Morales8, Noelia Martinez9, María Vidal1, Sonia Pernas9, Rafael Lopez10, Montse Muñoz1, Patricia Galvan1, Isabel Garau11, Luis Manzo12, Jesús Alarcón13, Eduardo Martínez14, Patricia Villagrasa4, Antonio LLombart-Cussac15, Aleix Prat1,5 and Paolo Nuciforo4. 1Hospital Clinic de Barcelona / IDIBAPS, Barcelona, Spain; 2University of Padova, Padova, Italy; 3Hospital Universitario Ramón y Cajal, Madrid, Spain; 4Molecular Oncology Group, Vall d’Hebron Institute of Oncology, Barcelona, Spain; 5SOLTI Breast Cancer Research Group, Barcelona, Spain; 6Hospital Clínico Universitario de Valencia / INCLIVA / CIBERONC, Valencia, Spain; 7Vall d’Hebrón University Hospital, Barcelona, Spain; 8Hospital Universitario Arnau de Vilanova de Lleida, Lleida, Spain; 9Institut Catala d’Oncologia, Hospitalat, Hospitalet del Llobregat, Spain; 10Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain; 11Hospital Son Llàtzer, Palma de Mallorca, Spain; 12Hospital Universitario 12 de Octubre, Madrid, Spain; 13Hospital Universitario Son Espases, Palma de Mallorca, Spain; 14Consortio Hospitalario Provincial de Castellón, Castellón de la Plana, Spain and 15Hospital Universitario Arnau de Vilanova de Valencia, Valencia, Spain.

**Background:** TILs in HER2+ breast cancer (BC) predict 1) prognosis in early setting, 2) complete pathological response (pCR) following neoadjuvant antiHER2-based therapy and 3) response to trastuzumab and pembrolizumab in the metastatic setting. However, less is known regarding changes in TILs during antiHER2-based treatment.

**Methods:** Stromal TILs where evaluated centrally using H/E slides in tumor samples from the PAMELA (NCT01973660) neoadjuvant phase II trial. Briefly, 151 women with HER2+ BC were treated with lapatinib and trastuzumab, and hormonal therapy if HR positive, for 18 weeks. TIL levels were determined at baseline (n=148), after 2 weeks of treatment (n=134) and at surgery (n=137). Expression of 560 genes, including immune-related genes (e.g. CD8A, CD4, PD1 and PDL1) was measured at the same timepoints (baseline n=151, 2-weeks n=144, surgery n=144) using the nCounter platform. Intrinsic subtyping at baseline was determined using the PAM50 gene expression predictor. Changes in TILs between 2 time-points were determined by paired t-tests. Correlation of TILs with gene expression was assessed by quantitative SAM analysis using a False Discovery Rate <1%. All statistical tests were two-sided and considered significant when p<0.05. All statistical analyses were carried out using the R software.

**Results:** Compared to baseline, a significant increase in TILs was observed at week 2 in HR- (p<0.001) and HER2-enriched (HER2-E) tumors (p=0.001), but not in HR+ (p=0.133) and non-HER2-E tumors (p=0.067). Within HR- and HER2-E tumors, increase in TILs at week 2 from baseline was observed regardless of pathological response at surgery (p=0.008); RD and HR- (p=0.037); pCR and HER2-E (p=0.010); RD and HER2-E (p=0.056). Compared to week 2, a significant decrease in TILs at surgery was observed in HR- (p=0.002) and HER2-E (p=0.003) tumors, but not in HR+ (p=0.616) and non-HER2-E tumors (p=0.578). Within HR- and HER2-E tumors, a significant decrease in TILs between week 2 and surgery was observed in tumors achieving pCR (p=0.004 and p=0.005), while, in tumors not achieving pCR, no significant tendency was observed (26.4% and 33.0% of tumors showed an increase and a decrease of TILs between week 2 and surgery). Nonetheless, the vast majority of residual tumors (non-pCR) at surgery had TILs above ≥5%: 34.3% 5-10%, 21.0% 10-20%, 15.2% 20-40% and 11.4% >40%. Finally, TILs scoring was found highly enriched (FDR<1%) for immune-related genes tracking activated CD8 T-cells (i.e. CD8A, CD3G, LAG3 and PD1). Expression of these immune genes consistently correlated with TIL levels across the 3 time-points.

**Conclusions:** In early HER2+ BC, a general increase in TILs is observed following 2 weeks of dual HER2 blockade. This observation is mostly observed in HR- and HER2-E subtype, but regardless of pathological response at surgery. After 2 weeks of treatment, TILs consistently decrease in patients achieving a pCR, whereas two main patterns of TILs expression are observed in patients with residual disease at surgery. Nonetheless, most residual tumors at surgery are inflamed (i.e. TILs ≥5%) and might be good candidates for clinical trials evaluating adjuvant immune checkpoint inhibitors.
Event-free survival by ADCC status from a follow-up study comparing SB3 (trastuzumab biosimilar) with reference trastuzumab for HER2 positive breast cancer in neoadjuvant setting

Mark D Pegram1, Xavier Pivot2, Javier Cortes3, Giuseppe Curigliano4, YeChan Yoon5, Jaeyun Lim5, Sujeong Song5 and Evelyn Hong5. 1Stanford Comprehensive Cancer Institute, Stanford, CA; 2Administrateur de l’Institut Régional du Cancer, Strasbourg, France; 3Ramon y Cajal University Hospital, Madrid, Spain; 4European Institute of Oncology, Milano, Italy and 5Samsung Bioepis Co., Ltd., Incheon, Korea.

Background: SB3 has been approved by the European Commission as a biosimilar of reference trastuzumab (TRZ). Equivalent breast pathologic complete response (bpCR) rate and comparable event-free survival (EFS) and overall survival between SB3 and TRZ have been reported.1-3 Upon monitoring quality attributes of TRZ for the development of SB3, a marked downward shift in antibody-dependent cell-mediated cytotoxicity activities (ADCC) was observed in TRZ lots with expiry dates from Aug 2018 to Dec 2019.4 Some of these lots were used in this study. The objective of this report is to evaluate event-free survival by ADCC status from an additional one-year follow-up study.

Methods: Patients with HER2 positive early or locally advanced breast cancer were randomly assigned to receive SB3 or TRZ in neoadjuvant setting concurrently with chemotherapy. Patients then underwent surgery followed by adjuvant SB3 or TRZ. After completion of therapy, patients from selected countries participated in a long-term follow-up study. In TRZ, patients exposed to at least one shifted ADCC lot and those not exposed to shifted ADCC lot during neoadjuvant period were considered as “Exposed” and “Unexposed,” respectively. EFS was defined as the time from the date of randomization to the date when the first event occurred and “Unexposed,” respectively. EFS was defined as the time from the date of randomization to the date when the first event occurred. An event was defined as disease recurrence or progression (local, regional, distant or contralateral) or death due to any cause. EFS after additional one-year follow-up was analyzed by ADCC status in the long-term follow-up set (LFS).

Results: A total of 367 patients (SB3, N=186; TRZ, N=181) were included in the LFS. Within TRZ, 55 patients were Unexposed and 126 patients were Exposed. At a median follow-up duration of 30.1 months in SB3 and 30.2 months in TRZ from initiation of study treatment, 4.8% patients in SB3, 3.6% in Unexposed and 10.3% in Exposed experienced events. 4.3% patients in SB3, 1.8% in Unexposed and 9.5% in Exposed experienced recurrence after surgery (Table). Two-year EFS rate was 96.7% in SB3, 98.2% in Unexposed and 92.5% in Exposed.

Conclusion: A significantly higher proportion of patients experienced events in Exposed compared to Unexposed (HR 0.07, 95% CI 0.01-0.58, p-value=0.0137). No significant difference in EFS was found between SB3 and Unexposed. Although this study has a relatively short follow-up and has not been powered to evaluate the impact of ADCC on survival, these results suggest a possible correlation between ADCC and clinical efficacy. Further long-term results will follow.

Dose justification for DS-8201a, a HER2-targeted antibody-drug conjugate, for HER2-positive breast cancer: Observed clinical data and exposure-response analyses

Kenji Tamura¹, Shanu Modi², Junji Tsurutani³, Shunji Takahashi⁴, Ian E Krop⁵, Hiroji Iwata⁶, Russell Wada⁷, Ophelia Yin⁸, Tushar Garimella⁹, Masahiro Sugihara⁹, Lin Zhang⁸, Caleb Lee⁸, Antoine Yver⁸ and José Baselga². ¹National Cancer Center Hospital, Tokyo, Japan; ²Memorial Sloan-Kettering Cancer Center, New York, NY; ³Kindai University Faculty of Medicine, Osakasayama, Osaka, Japan; ⁴The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Koto-ku, Tokyo, Japan; ⁵Dana-Farber Cancer Institute, Boston, MA; ⁶Aichi Cancer Center Hospital, Chikusa-ku, Nagoya, Japan; ⁷Certara USA, Inc., Princeton, NJ; ⁸Daiichi Sankyo, Inc., Basking Ridge, NJ and ⁹Daiichi Sankyo Co., Ltd., Tokyo, Japan.

Background
DS-8201a is a HER2-targeting antibody-drug conjugate with a high drug-to-antibody ratio of 7 to 8. A novel cleavable peptide-based linker joins the humanized HER2 antibody to a topoisomerase I inhibitor payload. In an ongoing phase 1 study (J101), DS-8201a was tested at doses of 0.8 to 8.0 mg/kg and tolerated with no predefined dose-limiting toxicities; 5.4 and 6.4 mg/kg doses were recommended for expansion. Subjects with HER2-positive breast cancer (BC) treated at these 2 doses had an overall response rate (ORR) of 54.5% (54/99). The phase 2 DESTINY-BREAST01 trial began enrollment in August 2017 with a dose-finding stage, including 5.4, 6.4, and 7.4 mg/kg. To determine the recommended dose for continued development in HER2-positive BC, a comprehensive analysis of observed data and exposure-response (ER) from both trials was performed.

Methods
A population-PK (PPK) model was developed using data from all subjects with available concentration data. Individual exposure parameters (C_{\text{min}}, C_{\text{max}}, \text{AUC}) were estimated from the PPK model and used in the ER analyses. ER analyses were conducted using logistic regression or Cox proportional hazard modeling for efficacy (ORR, duration of response, and PFS) and safety (nausea, diarrhea, left ventricular ejection fraction, neutropenia, anemia, thrombocytopenia, dose reductions due to TEAE, discontinuations due to TEAE, and interstitial lung disease [ILD]).

Results
As of 18 Apr 2018, in J101, there are 111 HER2-positive BC subjects treated at 5.4- or 6.4-mg/kg doses. As of 25 Apr 2018, DESTINY-BREAST01 enrolled 65 HER2-positive BC subjects across 3 doses (5.4, 6.4, and 7.4 mg/kg). Confirmed ORRs in J101 for HER2-positive BC subjects at 5.4 and 6.4 mg/kg were 52.6% (20/38) and 55.7% (34/61), respectively. In J101, AEs Grade ≥3 were reported in 35.6% (16/45) at 5.4 mg/kg and 50% (33/66) at 6.4 mg/kg. The relationship between DS-8201a intact C_{\text{min}} and ORR was statistically significant (P=0.035). There was a trend of improved PFS with higher intact exposures (P=0.238). Statistically significant relationships were observed between exposures and the following safety endpoints based on logistic regression: neutropenia (any grade, P=0.003; Grade ≥3, P=0.037), anemia (any grade, P=0.002; Grade ≥3, P<0.001), thrombocytopenia (any grade, P=0.021), dose reduction due to AE (P=0.003), discontinuations due to AE (P=0.035), and ILD/pneumonitis (any grade, P=0.017). Additionally, Cox proportional hazards modeling suggested higher risk of ILD with higher intact exposures (any grade, P<0.001; Grade ≥2, P=0.007).

Conclusions
In J101, DS-8201a demonstrated an acceptable safety profile and high response rates in HER2-positive BC at both doses. The ER analyses showed a statistically significant relationship between exposures and ORR (with a trend for higher PFS at higher doses), as well as exposures and risk of key adverse events. Considering the predicted benefit/risk profile, 5.4 mg/kg is the recommended dose for continued development of DS-8201a in the DESTINY-BREAST01 trial and in phase 3 clinical trials in HER2-positive BC.
The small molecule inhibitor of HER2, tucatinib, has potent and highly selective activity in preclinical modes of HER2-driven cancer

Neil A O'Brien¹, Dylan Conklin¹, Martina McDermott¹, Tong Luo¹, Raul Ayala¹, Shawnt Issakhanian¹, Suruchi Salgar¹, Sara Hurvitz¹ and Dennis J Slamon¹. ¹UCLA-Translational Oncology Research Laboratories, Los Angeles, CA.

Background: Pharmacologically targeting the HER2 oncoprotein provides clinical benefit for patients with HER2-amplified cancers. However, a significant number of patients do not respond to the currently approved HER2-targeted therapies, despite carrying the HER2-alteration. Small molecule inhibitors of HER2, that target other receptor tyrosine kinases such as EGFR (i.e. lapatinib), are approved and provide some clinical benefit but are often associated with increased toxicity. Tucatinib (ARRY-380) is an orally available, potent, highly selective small molecule inhibitor of the HER2 kinase. In this study, we assessed the in vitro and in vivo activity of tucatinib, relative to approved HER2-targeting molecules, in a panel of molecularly characterized breast cancer cell lines.

Materials and Methods: The growth inhibitory activity of tucatinib, trastuzumab and lapatinib were evaluated in a panel of 48 breast cancer cell lines molecularly characterized at baseline by genomic (array-CGH) and proteomic (Reverse Phase Protein Array; RPPA) profiling. IC₅₀ values for tucatinib and lapatinib were determined from direct cell counts using a Cellavista Cell Imaging System. Trastuzumab activity was measured as % inhibition of cell growth at fixed concentrations. In vivo efficacy of tucatinib was assessed in cell line xenograft models of HER2+/ER- and HER2+/ER+ breast cancers as a single agent or in combination with targeted therapies for breast cancer.

Results: A broad range of IC₅₀ values (3.2nM to >10µM), was seen for tucatinib with a high degree of selectivity for the HER2-amplified sub-type. High levels of total and phosphorylated HER2 (pHER2) accompanied by high levels of pEGFR and pHER3 enriched for sensitivity to tucatinib, confirming that HER2-driven cancers may be uniquely sensitive to tucatinib. The response profile for lapatinib was less clean, with responses also observed in HER2-low/EGFR-high cell lines. Sensitivity to tucatinib was also observed in HER2-amplified cell lines that were either de novo or acquired resistant to trastuzumab. Single agent tucatinib induced tumor regressions in a xenograft model of HER2+/ER- breast cancer. Tumor regressions were further enhanced by combination with trastuzumab. The combination of tucatinib plus trastuzumab was as efficacious and better tolerated than trastuzumab plus docetaxel or trastuzumab plus pertuzumab plus docetaxel. The triple combination of tucatinib plus hormonal blockade (fulvestrant) and CDK4/6 inhibition (abemaciclib) also induced robust tumor regressions, without significant body weight loss.

Discussion: These preclinical data highlight the potential of the HER2-selective small molecule inhibitor, tucatinib, to provide benefit to patients with HER2-amplified cancers. Furthermore, our biomarker analysis of response to tucatinib has identified a HER2-driven signature within the HER2-amplified sub-type that selects for sensitivity to tucatinib. Selecting patients based on this profile may further enrich for individuals most likely to benefit from tucatinib-based therapies.
Neratinib in combination with trastuzumab is superior to each alone and to pertuzumab plus trastuzumab in HER2-positive in vivo breast cancer models.

1 Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX; 2 Dan L. Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX; 3 Baylor College of Medicine, Houston, TX and 4 Puma Biotechnology Inc., Los Angeles, CA.

Background: Lapatinib (L) plus trastuzumab (T) alone or with endocrine therapy for HER2+/ER+ tumors but without chemotherapy, yielded complete tumor eradication in xenograft models. In neoadjuvant trials (NCT00548184, 00999804, 01973660), a substantial number of patients achieved pathologic complete response with this same strategy. The irreversible pan-HER inhibitor neratinib (N) has been recently approved by the FDA for early stage HER2+ breast cancer and has shown greater potency compared to L in the preclinical setting. However, the therapeutic efficacy of N in combination with T (N+T) and how it compares to pertuzumab (P) +T (without chemotherapy) has not been well studied.

We hypothesize that dual HER2 inhibition using N+T will be highly efficacious and more effective than P+T due to more complete blockade of the HER pathway. Here, we evaluate the therapeutic efficacy of N, P, and T, either alone or in combination, with a primary focus on comparing N+T vs. P+T in established cell line- and patient-derived xenograft (PDX) models.

Methods: Athymic nude and SCID/Beige mice bearing BT474-AZ cell line (ER+/HER2+), and BCM-3963 PDX tumors (ER-/HER2+, wild-type PIK3CA), respectively were randomized to vehicle, N (20mg/kg, 5 days/week), T (10mg/kg, twice a week), P (6mg/kg, once a week), N+T, or P+T, with simultaneous estrogen (E2) deprivation (ED) in BT474-AZ model. Treatment response was assessed by biweekly tumor measurements. Study endpoints included time to tumor regression (TTR) and progression (TTP) (tumor halving/doubling over baseline, respectively), and the rate and time of complete response (CR and TCR, respectively). Results were analyzed using survival analysis (Kaplan-Meier estimates) and generalized Wilcoxon tests.

Results: In the BT474-AZ model, mice treated with E2+vehicle and ED+vehicle showed steady tumor growth, with a median TTP of 8 and 25 days, respectively. While tumor regression was observed in 100% of mice treated with N, P, T, N+T, and P+T, tumors treated with N+T regressed faster compared to P (p<0.001), T (p=0.004), and P+T (p=0.044). Further, N+T was superior to N (p=0.018) and T (p=0.007) alone in achieving accelerated CR. In the BCM-3963 model, tumors treated with vehicle, T, P, and P+T continued to grow with a median TTP of 11, 16, 19, and 17 days, respectively. In contrast, CR was achieved in 100% of N and N+T treated mice. Importantly, combining N with T accelerated the attainment of CR compared to N alone (p=0.026).

Molecular and pathologic analysis of short-term treated tumors in both models to evaluate alterations in HER signaling, cell proliferation, and apoptosis is ongoing.

**Conclusions:** Our findings establish the preclinical efficacy of combining N with T for HER2+ breast cancer and warrant further clinical testing to investigate the efficacy of N+T without chemotherapy in the neoadjuvant setting for patients with HER2+ breast cancer.
ZW49, a HER2 targeted biparatopic antibody drug conjugate for the treatment of HER2 expressing cancers

Kevin J Hamblett¹, Stuart D Barnscher², Rupert H Davies¹, Phil W Hammond¹, Andrea Hernandez², Grant R Wickman², Vincent KC Fung³, Tong Ding³, Graham Garnett³, Adam S Galey², Patricia Zwierzchowski³, Brandon C Clavette³, Geoff C Winters², Jamie R Rich³, Gerry J Rowse², John S Babcook² and Diana Hausman¹. ¹Zymeworks Biopharmaceuticals Inc., Seattle, WA and ²Zymeworks Inc., Vancouver, BC, Canada.

Background: HER2-targeted therapies have transformed the treatment of patients with HER2-expressing breast and gastric cancers. Despite this, there remains a need for new treatments that are well tolerated and effective not only for cancers with high HER2 expression levels but also those with lower levels of expression. ZW49 is an antibody drug conjugate (ADC) that combines a novel auristatin payload (potent anti-cancer agent) with the unique mechanisms of action of the anti-HER2 biparatopic antibody, ZW25, which binds to the same domains as trastuzumab and pertuzumab. In preclinical studies in cancer cell lines with low to high levels of HER2 expression, ZW25 is associated with increased binding and internalization compared to trastuzumab, while the novel N-acyl sulfonamide auristatin payload has demonstrated increased in vivo tolerability compared to other microtubule inhibitors. ZW49 therefore has the potential to address unmet medical need across a range of HER2-expressing cancers.

Methods: Multiple in vitro and in vivo experiments were performed to characterize ZW49 as a potential therapeutic candidate. Internalization and cell growth inhibition of ZW49 were evaluated in HER2-expressing cell lines. Anti-tumor activity was assessed in patient-derived xenograft (PDX) tumor models of HER2 low and high expressing breast cancers. Tolerability was assessed in a 6-week repeat-dose non-GLP toxicology study in non-human primates (NHP) with intravenous administration of ZW49 at either 9 mg/kg or 12 mg/kg once every two weeks.

Results: In vitro, ZW49 was more rapidly internalized into HER2-expressing cells compared to a monospecific trastuzumab-ADC. ZW49 also displayed potent in vitro cell growth inhibition in several breast cancer cell lines with a range of HER2 expression. This activity was confirmed in multiple in vivo PDX models, including a HER2 IHC 3+ HBCx-13b xenograft where two doses of ZW49 at 3 mg/kg or higher generated tumor regressions, and a HER2 IHC 1+ ST-910 xenograft where a single dose of ZW49 at 6 mg/kg or higher generated regressions. In both models, regressions occurred at exposures that were well tolerated in NHP. In a repeat dose pilot non-GLP study the highest dose tested (12 mg/kg) was considered to be the no observed adverse effect level (NOAEL) and a GLP repeat-dose toxicology study was ongoing at the time of abstract submission.

Conclusions: ZW49 is a novel biparatopic HER2-targeted ADC that demonstrated anti-tumor activity in low and high HER2-expressing breast cancer cell lines and PDX models. Notably, tumor regressions were observed at exposure levels that were well tolerated in NHP. These results support the potential of ZW49 as a novel therapeutic agent that may help address unmet medical need in patients with high and low HER2-expressing cancers.
Eribulin, trastuzumab, and pertuzumab as first-line therapy for patients with HER2-positive metastatic breast cancer: A multicenter, collaborative, open-label, phase II clinical trial for the SBCCSG-36 investigators

Kenichi Inoue¹, Jun Ninomiya², Katsuhiko Okubo³, Takashi Nakakuma⁴, Hirofumi Yamada⁵, Kei Kimizuka⁶, Tohru Higuchi⁷ and Tsuyoshi Saito⁷. ¹Saitama Cancer Center, Saitama, Japan; ²Ninomiya Hospital, Saitama, Japan; ³Toda Chuo General Hospital Saitama, Saitama, Japan; ⁴Ageo Central General Hospital, Saitama, Japan; ⁵Sekishindo Hospital, Saitama, Japan; ⁶Kasukabe Medical Center, Saitama, Japan and ⁷Saitama Red Cross Hospital, Saitama, Japan.

Background: Docetaxel, trastuzumab, and pertuzumab (DTP) therapy is established first-line therapy for patients with HER2-positive metastatic breast cancer (HER2 + MBC). However, the poor tolerability of docetaxel impedes its long-term administration. The safety of eribulin, trastuzumab, and pertuzumab (ETP) therapy for HER2 + MBC has been confirmed in Japan. We examined the primary endpoint—overall response rate, the secondary endpoints—time to treatment failure, progression-free survival, and overall survival, as well as adverse events (AEs) of ETP therapy. (University Hospital Medical Information Network identifier:000021585)

Methods: Eribulin 1.4 mg/m²/day iv (days 1 and 8), trastuzumab 8 mg/kg iv over 90 min (initial dose) and 6 mg/kg iv over 30 min (second and subsequent doses), and pertuzumab 840 mg/body over 60 min (initial dose) and 420 mg/body over 30 min (second and subsequent doses) were administered. Cycles consisting of 2 doses of eribulin and 1-week drug holiday were repeated. Patients were treated with trastuzumab and pertuzumab when AEs developed that did not allow medication continuation by reducing the dose of eribulin. Antitumor effect was assessed according to RECIST version 1.1. and toxicities to CTCAE Japanese version 4.0. All patients provided written informed consent before enrollment. The study protocol was approved by the Institutional or Central Ethics Committee, and the study was conducted in accordance with the Declaration of Helsinki, Good Clinical Practice, and local ethical and legal regulations.

Results: 25 female patients (median age: 57 years [41-75]) were enrolled from April 18, 2016, through November 22, 2017. Twenty-four had performance status (PS) 0, 1 PS 1, 8 stage 4 breast cancer, and 17 metastatic breast cancer. Anthracycline, taxane, and trastuzumab were administered as neoadjuvant and adjuvant pharmacotherapies to 13, 15, and 14 patients, respectively. Primary tumor was positive for estrogen and progesterone receptors in 12 and 6 patients, respectively. Lung, liver, and bone metastases occurred in 9, 9, and 6 patients, respectively. Three (12%), 17 (68%), 1 (4%), 1 (4%), and 2 (8%) patients showed complete response (CR), partial response (PR), long-term stable disease (LSD; stable disease ≥24 weeks), stable disease (SD; stable disease <24 weeks), and progression disease (PD), respectively; 1 (4%) was unassessable because ETP therapy could not be conducted due to the grade 3 infusion reaction of pertuzumab. Major AEs were neutropenia, anemia, fatigue, peripheral neuropathy, alopecia, and anorexia. The overall response rate (CR+PR) was 80.0% (95% confidence interval 59.3-93.2%). The median follow-up was 10.1 months [3.9-21.5]. Six and 3 patients showed tumor deterioration and died of breast cancer, respectively.

Conclusions: Similar to DTP, ETP showed high response rates and good safety as first-line therapy for HER2 + MBC.
Evaluating preclinical efficacy of anti-HER2 drug combinations using ER+/HER2 mutant models

Shyam M Kavuri, Vaishnavi Devarakonda, LaTerrica C Williams, Sinem Seker, Jonathan T Lei, Purba Singh, Airi Han, Meenakshi Anurag, Kimberly R Holloway, Alana L Welm and Matthew J Ellis. 1Baylor College of Medicine, Lester and Sue Smith Breast Center, Houston, TX and 2Huntsman Cancer Institute, University of Utah, Salt Lake City, UT.

Background
Until recently, HER2 gene amplification was the only mechanism of HER2 activation recognized. However, activating HER2 mutations have been noted in different cancer types. A trials of HER2 mutant breast cancer and the subsequent SUMMIT trial data have shown that monotherapy with the pan-HER drug neratinib as showed clinical efficacy, but with poor response durability. This study therefore investigates the preclinical efficacy of anti HER2 agents alone or in combination with endocrine therapy agents or in combination with CDK4/6 inhibitors using ER+/HER2 mutant cell lines and ex vivo HER2 mutant patient derived xenograft (PDX) model to define a more effective treatment approach.

Methods
ER+ breast cancer cell lines (T47D and MCF7) stably expressing HER2V777L, and ER+/HER2 mutant PDX model (HER2G778_P780dup) were used to examine HER2 signaling and drug responses. Signaling downstream mutant HER2 was examined by immunoblot analysis. Effects of neratinib alone, neratinib + fulvestrant, and neratinib + abemaciclib on cell growth were examined in ER+/HER2 mutant cell lines and in an ex vivo HER2G778_P780dup.

Results
We found that MCF7/T47D cells expressing HER2V777L and HER2G778_P780dup PDX tumors showed strongly activated autophosphorylation of HER2 and increased expression of CDK4, CDK6, phospho-Rb, and cyclin D1 as compared to MCF7/T47D cells expressing HER2WT or ER+/non-HER2mut PDX modes, suggesting that HER2 mutations preferentially depend on CDK4/6 signaling for cell growth. Additionally, we showed that activating MCF7 HER2V777L cause resistance to endocrine therapy treatment (fulvestrant IC50 >5μM). Further, we show that neratinib alone is effective at higher concentrations (IC50 < 2μM) in MCF7/HER2V777L cells. We also demonstrate that abemaciclib alone exhibited moderate activity against MCF7 HER2V777L cells (IC50 < 0.4μM) and additional activity in combination with neratinib (IC50 < 0.06μM) was seen. Moreover, ex vivo HER2G778_P780dup cells are relatively resistant to fulvestrant alone (IC50 < 0.2μM), neratinib alone (IC50 < 0.006μM), abemaciclib alone (IC50 < 0.04μM), and neratinib in combination with abemaciclib (IC50 < 0.005μM), suggesting that patients harboring ER+/HER2-mutant tumors may benefit from neratinib in combination with abemaciclib.

Conclusion
These preclinical data suggest that neratinib monotherapy may not be effective to treat ER+/HER2 mutant patients and we propose that simultaneous targeting of both HER2 and the CDK4/6 axis will be required for effective treatment of ER+ breast cancers harboring HER2 activating mutations.
Efficacy and safety of shorter duration of adjuvant trastuzumab for patients with HER2 positive early breast cancer: A meta-analysis of randomized controlled trials

Juanjuan Li¹,², Guannan Wang¹,², Qi Wu¹, Chuang Chen¹, Yi Tu¹, Feng Yao¹, Wen Wei¹, Shengrong Sun¹, Cesar August Santa-Maria³ and Peiliang Geng⁴. ¹Renmin Hospital of Wuhan University, Wuhan, China; ²Johns Hopkins University School of Medicine, Baltimore, MD; ³Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins, Baltimore, MD and ⁴Cancer Center, Chinese PLA General Hospital, Beijing, China.

Background: Trastuzumab has been shown to be able to improve disease free survival (DFS) and overall survival (OS) in HER2-positive breast cancer patients. Adjuvant trastuzumab is empirically recommended for 1 year as a standard regimen. However, several studies claimed that shorter duration of adjuvant trastuzumab is non-inferior to 12 months treatment with reduced cardiac toxicities and costs.

Methods: PubMed, EMBASE, Cochrane Library, Google scholar Web, ISI Web of Science, BIOSIS and CNKI, and major conference abstracts were searched systematically in June 2018 to identify eligible non-inferiority studies comparing the intervention outcomes of adjuvant trastuzumab in chemotherapy for women with HER-2 positive breast cancer between short-term and 1-year treatments. Hazard-Ratios (HR) and corresponding 95% Confidence Intervals (CI) were calculated to compare OS and DFS of trastuzumab between short-term and long-term treatments. Pooled data of Odds-Ratio was analyzed for cardiac toxicities.

Results: 5 articles were finally eligible in the study. Totally, there were 11,376 women with HER-2 positive early breast cancer, with 5,684 in short-term group and 5,692 in the 1-year group. We found a distinct difference of DFS (HR=1.19, 95% CI=1.08-1.30) and OS (HR=1.22, 95% CI=1.07-1.39) between short-term and 12 months trastuzumab in the total analysis, which demonstrated short-term treatment exhibited a worsening trend on DFS and OS. Subgroup analysis was performed based on estrogen receptor (ER) and lymph node status, and no statistical interaction could be found (p=0.12, 0.52, respectively). The two groups with different duration of trastuzumab treatment displayed statistically significant difference for cardiotoxicities, which favored shorter duration (OR=0.54, 95% CI=0.38-0.77).

Conclusions: 1-year adjuvant trastuzumab remains the standard strategy for HER2 positive early breast cancer, however, a concomitant higher risk of associated cardiac adverse effects should not be ignored.
Pertuzumab, trastuzumab, and docetaxel for HER2-positive early or locally advanced breast cancer in the neoadjuvant setting: Efficacy and safety analysis of a randomized phase III study in Asian patients (PEONY)

Zhimin Shao1, Da Pang2, Hongjian Yang3, Wei Li4, Shusen Wang5, Shude Cui6, Ning Liao7, Yongsheng Wang8, Chuan Wang9, Yuan-Ching Chang10, Hweichung Wang1, Seok Yun Kang12, Zefei Jiang13, Junjie Li1, Julian Zhou14, Betsy Althaus15, Yixiang Mao14 and Jennifer Eng-Wong15.

Fudan University Shanghai Cancer Center, Shanghai, China; Harbin Medical University Cancer Hospital, Harbin, China; Zhejiang Cancer Hospital, Hangzhou, China; The First Hospital of Jilin University, Changchun, China; Sun Yat-sen University Cancer Center, Guangzhou, China; Henan Cancer Hospital, Zhengzhou, China; Guangdong General Hospital, Guangzhou, China; Shandong Cancer Hospital, Jinan, China; Fujian Medical University Union Hospital, Fujian, China; Mackay Memorial Hospital, Taipei City, Taiwan; China Medical University Hospital, Taichung City, Taiwan; Ajou University School of Medicine, Suwon, Republic of Korea; The Affiliated Hospital of Military Medical Sciences (The 307th Hospital of Chinese People's Liberation Army), Beijing, China; Roche Product Development, Shanghai, China and Genentech, Inc., South San Francisco, CA.

Background
Pertuzumab and trastuzumab (P and H; F. Hoffmann-La Roche Ltd, Basel, CH) bind to distinct HER2 subdomains and have complementary modes of anticancer activity in HER2-positive breast cancer (BC). A global Phase II study (NeoSphere) reported that neoadjuvant treatment with P+H+docetaxel (D) significantly increased breast pathologic complete response (bpCR) vs H+D in patients (pts) with early/locally advanced/inflammatory HER2-positive BC (Gianni et al. Lancet Oncol 2012). PEONY (NCT02586025), a randomized, multicenter, double-blind, placebo-controlled, Phase III trial conducted in an Asian population (mainland China, Taiwan, Korea, Thailand), primarily compared the efficacy, safety, and tolerability of P+H+D vs placebo (Pla)+H+D in the neoadjuvant setting. We present data from the primary analysis.

Methods
Pts with centrally confirmed HER2-positive early (T2–3, N0–1)/locally advanced (T2–3, N2 or N3; T4, any N) BC were randomized 2:1 to 4 cycles of P+H+D or Pla+H+D every 3 weeks, before surgery: P, 840 mg loading/420 mg maintenance doses (or Pla); H, 8 mg/kg loading/6 mg/kg maintenance; D, 75 mg/m². Post-surgery, pts received 3 cycles of fluorouracil, epirubicin, and cyclophosphamide followed by 13 cycles of P+H or Pla+H for up to 1 year (total of 17 HER2-targeted therapy cycles). The primary endpoint was total pCR rate (tpCR; absence of any residual invasive cancer in the breast and lymph nodes [ypT0/is, ypN0]) assessed by independent review committee (IRC) when pts completed surgery with a tpCR assessment. Missing/invalid assessments were considered residual disease.

Results
A total of 329 pts were randomized: 219 to P, 110 to Pla. Baseline characteristics were well balanced. Most pts had early BC (69.6%) and were from mainland China (79.3%). In the intention-to-treat population, the tpCR rate by IRC was 39.3% in the P arm and 21.8% in the Pla arm; a clinically and statistically significant difference of 17.5% (95% CI 6.9–28.0; p=0.0014). The local pathologist-assessed tpCR rates were 39.3% and 20.9%, respectively. A consistent treatment benefit of P vs Pla was observed in subgroups. Incidences of grade ≥3 adverse events (Aes) were 48.6% in the P arm and 41.8% in the Pla arm. Of the most common grade 3 Aes (≥3% of pts), neutropenia was higher in the P arm (38.1% vs 32.7%). Of the most common any-grade Aes (≥5%), diarrhea was higher in the P arm (38.5% vs 16.4%). No heart failure (New York Heart Association Functional Classification III or IV) or significant left ventricular ejection fraction decline events (≥10 percentage points from baseline and to <50%) were observed during neoadjuvant therapy.

Conclusions
PEONY met its primary endpoint: P+H+D resulted in a clinically meaningful and statistically significant improvement in the tpCR rate by IRC vs Pla+H+D for the neoadjuvant treatment of HER2-positive early/locally advanced BC in Asian pts. Safety data were in line with the known P safety profile and generally comparable between treatment arms. Results were similar to NeoSphere, and confirm that P+H+D provides superior anticancer activity to H+D alone.
Pathologic complete response (pCR) in locally advanced HER2+ (HER2+) breast cancer (BC) treated with anthracycline-free neoadjuvant therapy

George Somlo¹, James Waisman¹, Yuan Yuan¹, Laura Kruper¹, Paul Frankel¹, Veronica Jones¹, Tumyan Lusi¹, Daniel Schmolze¹, John Yim¹, Arti Hurria¹ and Joanne Mortimer¹. ¹City of Hope, Duarte, CA.

Background: Response to neoadjuvant therapy is a predictor of progression-free and overall survival in HER2+. To decrease treatment associated toxicities in patients with HER2+ breast cancers we utilized a non-anthracycline regimen with pertuzumab (pert), trastuzumab (trast), and nab-paclitaxel (nab). Pre- neoadjuvant therapy biopsies were procured to evaluated possible biological predictors of pathologic complete response (pCR).

Methods: Women with locally advanced HER2 positive breast cancers were recruited from our breast cancer clinics. After obtaining informed consent for this IRB-approved trial, patients were treated with 6 cycles of pertuzumab (day 1 every 21 days [d]), and weekly trastuzumab 2 mg/kg with and nab-paclitaxel 100 mg/m². Formalin fixed paraffin embedded (FFPE) or frozen biopsies pre-NT and post-NT were collected, along with blood samples at pre-treatment, and at the end of study for correlative analysis.

Results: Accrual is complete, with 42 of the 45 HER2+ patients assessed for pCR rate (3 too early to evaluate). The median age was 54 yrs (range 31-77 years). 12 patients were stage 3, 26 stage 2, and 1 stage 1 patient. The pCR rate was 64.2% (27/42), with 73.7% (14/19) in ER/PR negative patients and 56.5% (13/23) in ER/PR positive patients. The initial primary tumor size was similar for in those who achieved pCR and non-pCR patients (mean 4.1 cm vs 3.2 cm, respectively). Most patients required dose modifications. Grade 3 AEs reported included 6 patients with hypertension, 3 patients with hematological AEs, 3 patients with elevated LFTs, and 2 patients with diarrhea.

Conclusions: This anthracycline-free regimen in HER2+ BC can achieve promising pCR response rates, with toxicities well-managed with dose modifications. Results of correlative analysis will be presented.
What to do with trastuzumab therapy after achieving radiological complete remission (rCR) in HER2+ metastatic breast cancer (MBC)?

Tessa G Steenbruggen¹, Nathalie I Bouwer², Carolina H Smorenbury¹, Hanah N Rier², Agnes Jager³, Karin J Beelen⁴, Albert J ten Tije⁵, Paul C de Jong⁶, Jan C Drooger⁷, Cynthia Holterhues⁸, Hugo M Horlings¹, Joyce Sanders¹, Mark-David Levin² and Gabe S Sonke¹. ¹The Netherlands Cancer Institute, Amsterdam, Noord-Holland, Netherlands; ²Albert Schweitzer Hospital, Dordrecht, Zuid-Holland, Netherlands; ³Erasmus MC Cancer Institute, Rotterdam, Zuid-Holland, Netherlands; ⁴Reinier de Graaf Hospital, Delft, Zuid-Holland, Netherlands; ⁵Amphia Hospital, Breda, Brabant, Netherlands; ⁶Sint Antonius Hospital, Utrecht, Netherlands; ⁷Ikazia Hospital, Rotterdam, Zuid-Holland, Netherlands and ⁸Haga Hospital, The Hague, Zuid-Holland, Netherlands.

**Intro** MBC is generally considered incurable, but patients with HER2+ disease treated with trastuzumab do relatively well and some have an exceptional durable response and survive over 10 years. We analyzed the clinical-pathological characteristics associated with long-term survival in patients with HER2+ MBC treated with trastuzumab. In addition, we studied the effect of stopping trastuzumab in case of rCR.

**Methods** We included all patients with HER2+ MBC treated with first- or second-line trastuzumab-based palliative therapy between January 2000 and December 2014 in 8 Dutch hospitals (Netherlands Cancer Institute, Erasmus Medical Center, Albert Schweitzer Hospital, Reinier de Graaf Hospital, Amphia Hospital, St. Antonius Hospital, Ikazia Hospital, Haga Hospital). Patients were identified through the Netherlands Cancer Registry and linkage with the institutes' tumor registries. Data was collected from medical records using case record forms. Primary endpoint was overall survival (OS), defined as first-date of MBC until death due to any cause. Kaplan-Meier survival estimates were calculated and multivariable Cox-regression models used to identify prognostic factors for improved survival. Time to progression (TTP) after achieving rCR for patients who continued and stopped trastuzumab and breast cancer specific survival were secondary outcomes.

**Results** We included 744 patients (median age 53, range 24-87). Median follow-up (FU) was 109 months (range 0-178). Clinical factors associated with improved survival in multivariable analyses were single-organ metastases, ER-positivity, no skin or liver metastases, no prior trastuzumab, local therapy of metastatic disease and achievement of rCR. In line with our first single center analyses¹, achievement of rCR was the strongest predictor of improved survival (multivariable HR 0.30, 95%CI 0.20-0.46). RCR was observed in 71 patients (10%), of whom 60 had been treated with trastuzumab and chemotherapy, 9 with trastuzumab and hormonal therapy, and 2 with hormonal therapy. In patients with rCR the estimated 10-year OS was 53% versus 7% in patients who did not achieve rCR (p<0.001).

Thirty patients stopped trastuzumab after achieving rCR. Median time between onset of rCR and last gift of trastuzumab in these patients was 6 months (0-132). Twenty-one patients (70%) remain in complete remission after a median FU of 75 months (range 54-90) since onset of rCR. Nine patients experienced disease progression after a median time of 14 months (range 9-62) since last gift of trastuzumab. Of these, 8 patients died due to MBC and one again achieved an ongoing rCR. Out of 39 patients who continued trastuzumab after achieving rCR, 12 are in ongoing remission after a median FU of 71 months (range 51-91). In this group median TTP was 14 months (range 5-23).

**Conclusion** Achieving rCR is strongly associated with long-term survival in patients with HER2+ MBC. Seventy percent of patients who stopped trastuzumab after achieving rCR remained in remission, suggesting this can be an attractive approach in selected patients. External validation of these findings is required, however, as well as additional analyses to characterize the patients -and their tumors- who achieved rCR.

Matching the critical function of the biosimilar ABP 980 and trastuzumab: Totality of evidence and scientific justification for extrapolation across trastuzumab indications

Hans-Christian Kolberg¹, Marco A Colleoni², Zorica Tomasevic³, Olga Ponomarova⁴, Helen J McBride⁵, Hans Tesch⁶ and Vladimir Hanes⁵.
¹Marienhospital BottropGmbH, Klinik für Gynäkologie und Geburtshilfe, Bottrop, Germany; ²Divisione di Senologia Medica, Milan, Italy; ³Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; ⁴R.E.Kavetsky Institute of Experimental Pathology, Kiev, Ukraine; ⁵Amgen Inc., Thousand Oaks, CA and ⁶Hämatologisch-Onkologische Gemeinschaftspraxis, Frankfurt am Main, Germany.

Background
Approval of biosimilars is based on the totality of evidence (TOE) supporting clinical equivalence between the proposed biosimilar and the reference product (RP). TOE comprises comprehensive studies designed to evaluate structural, functional, pharmacokinetic (PK), and clinical similarity. TOE provides scientific justification for possible extrapolation across indications that share a common mechanism of action. ABP 980 has been shown to be biosimilar to trastuzumab using robust analytical and functional assessments. Results from phase 1 and phase 3 studies have shown PK and clinical similarity to trastuzumab. Here, we extend the similarity assessment using multiple orthogonal assays for the primary mechanism of action.

Methods
Multiple lots of ABP 980, trastuzumab (US) and trastuzumab (EU) were compared in the biological activity assessment. In addition to the primary assessment, we conducted additional characterization assays assessing human epidermal growth factor receptor 2 (HER2) cell binding, inhibition of HER2 signaling, inhibition of HER2 ligand-independent proliferation in gastric cancer cells, and a synergy study conducted with docetaxel chemotherapy in gastric cancer cells. HER2 cell-based binding assays were performed using SKBR-3 target cells and a competitive inhibition format. Inhibition of AKT phosphorylation was assessed by comparing the effect of test samples on basal pAkt in the BT-474 breast cancer line. Inhibition of HER2 ligand-independent proliferation was assessed using the gastric cell line NCI-N87 and specificity of inhibition was evaluated using MCF-7 cells that do not have amplified HER2 expression. The synergy study was conducted using NCI-N87 gastric cancer cells and docetaxel using the Combinatorix™ method.

Results
Relative cell binding to HER2 was similar (ABP 980, 93%-112%; trastuzumab [EU], 98%-109%; trastuzumab [US], 96%-102%). Synergy scores (mean ± SD) with docetaxel (in NCI-N87 cells) for ABP 980, trastuzumab (US) and trastuzumab (EU), respectively, were 16.1 ± 1.4, 16.4 ± 1.8, and 15.8 ± 1.3. Functionally, ABP 980 and trastuzumab similarly inhibited HER2 ligand-independent proliferation in NCI-N87 gastric cancer cells, exhibited specificity against MCF7 non-amplified HER2 expressing breast cancer cells, and showed similar inhibition of pAkt phosphorylation in BT-474 breast cancer cells.

Conclusions
In this study, we show similar activity between ABP 980 and trastuzumab RP, either alone or in combination with docetaxel, in both breast cancer and gastric cancer cell lines. Our results add to the TOE supporting the biosimilarity of ABP 980 and trastuzumab, and the justification for extrapolation across its approved indications.
2018 San Antonio Breast Cancer Symposium®

Progression free survival (PFS) and overall survival (OS) of patients treated with trastuzumab emtansine (T-DM1) after previous treatment with pertuzumab in patients with advanced breast cancer (NCT02338167)

Background
Studies leading to the approval of trastuzumab emtansine (T-DM1) have been conducted without pertuzumab as previous therapy. Therefore data about patient characteristics and the efficacy of T-DM1 after a treatment with pertuzumab is scarce. Aim of this study was to analyze a real world patient cohort of advanced breast cancer (aBC) patients, who were treated with T-DM1 after a treatment containing pertuzumab in the metastatic setting with regard to patient characteristics and progression free survival (PFS).

Methods
The PRAEGNANT metastatic breast cancer registry (NCT02338167) is a prospective registry for metastatic breast cancer patients with focus on molecular biomarkers. Patients of all therapy lines with any kind of treatment are eligible for this registry. Collected data comprises all relevant patient and tumor characteristics, therapies, adverse events, quality of life, patient reported outcomes, response and survival (PFS/OS). Here we report on the patient characteristics and PFS data for HER2 positive patients treated with T-DM1 after a treatment with pertuzumab. Patients had to be included before or at the beginning of the T-DM1 therapy.

Results
A total of 58 patients could be identified, who were suitable for the analysis. Of those 34 were treated in the second line, 14 in the third line and 10 in the fourth line or higher. Most of the pertuzumab therapies before T-DM1 were conducted in first line (n=46; 79.3%). Median PFS for all patients was 4.8 months (95% CI: 3.0-7.8 months). Median PFS for patients treated in the 3rd line and 4th line or higher was 4.2 months (95% CI: 2.1-NA) and 4.0 months (95% CI: 1.8-NA), respectively. In patients treated 2nd line with T-DM1 PFS was 7.7 months (95% CI: 2.8-12.2).

Conclusion
T-DM1 is effective as 2nd and further line therapy following pretreatment with pertuzumab. Overall PFS was about 5 months with 7.7 months as 2nd line therapy. The PFS in higher therapy lines might be shorter. As the sample size of this real world cohort was rather low and analyses have to be considered exploratory, this data need to be confirmed in studies with a larger sample size.
Randomized phase II study of lapatinib plus vinorelbine versus vinorelbine in patients with HER2 positive metastatic breast cancer progressed after lapatinib and trastuzumab treatment

Background
The continuum of anti-HER2 agents is regarded as a standard strategy for HER2 positive metastatic breast cancer patients who had progressed disease with anti-HER2 agent-containing treatments. However, there has been lack of data on which agents should be continued and how long continuous anti-HER2 therapies would be effective. This study was aimed to evaluate the efficacy of lapatinib plus vinorelbine in HER2 positive metastatic breast cancer patients who had progressed on both trastuzumab and lapatinib treatments.

Methods
A total of 149 patients were randomly assigned to lapatinib with vinorelbine (LV) (n=75; lapatinib, 1000mg daily; vinorelbine 20mg/m\(^2\) D1,D8 q3w) or vinorelbine alone (V) (n=74; 30mg/m\(^2\) D1,D8 q3w). The stratification factors were followings; 1) visceral metastasis, 2) previous response to lapatinib treatment, CR+PR vs. SD ≥12 weeks. The primary endpoint was progression free survival (PFS) rate at 18 weeks. The secondary endpoints were objective response rate (ORR), PFS, and overall survival (OS).

Results:
Both arms were well balanced in various clinical factors. The median number of previous anti-HER2 therapies were 2 (range 2-5). There was no significant difference in PFS rate at 18 weeks between LV and V arms (44.0% vs 36.5%, p=0.44). ORR was 19.7% in LV arm and 16.9% in V arm (p=0.881). PFS and OS did not differ between two arms (LV vs V; median PFS, 16weeks vs 12 weeks, HR= 0.86, 95% CI 0.61-1.22, p=0.41; median OS, 15.0 months vs 18.9 months, HR= 1.07, 95% CI 0.72-1.58, p=0.72). In subgroup analysis, there was no difference in PFS and OS between two arms according to previous response to lapatinib (median PFS, CR+PR vs. SD ≥12 weeks, 12.1weeks vs17.4 weeks; HR= 1.242, 95% CI 0.881-1.751, p=0.215; median OS, 14.9 months vs. 19.4 months; HR= 1.179, 95% CI 0.797-1.744, p=0.41). Most common adverse events in both arms were neutropenia which was more often observed in V arm (55% vs 73%, p=0.03). Overall, the profiles of adverse events were similar in both arms and all were manageable.

Conclusion
Lapatinib plus vinorelbine treatment was tolerable, however, it did not demonstrate the clinical benefits compared to vinorelbine alone in HER2 positive metastatic breast cancer patients after progression on both trastuzumab and lapatinib.
Use of subcutaneous and intravenous trastuzumab: Real-world experience from three hospitals in Sweden

Antonis Valachis\textsuperscript{1}, Lena Carlsson\textsuperscript{2}, Marie Sundqvist\textsuperscript{3}, Bing Li\textsuperscript{4}, Flaminia Chiesa\textsuperscript{4}, Milica Uhde\textsuperscript{4} and Thibaut Sanglier\textsuperscript{5}. \textsuperscript{1}Faculty of Medicine and Health, Örebro University Hospital, Örebro, Sweden; \textsuperscript{2}Sundsvall County Hospital, Sundsvall, Sweden; \textsuperscript{3}Breast Unit, Kalmar County Hospital, Kalmar, Sweden; \textsuperscript{4}Real World and Analytic Solutions (RWAS), IQVIA, Stockholm, Sweden and \textsuperscript{5}PHC Data Science, F. Hoffmann-La Roche Ltd, Basel, Switzerland.

Background
Trastuzumab (H; F. Hoffmann-La Roche Ltd, Basel, CH) reduces recurrence and improves survival in patients (pts) with HER2-positive early breast cancer (EBC). Two formulations which are noninferior in terms of pathologic complete response and serum trough concentration (Ismail et al. \textit{Lancet Oncol} 2012) are available, for intravenous (IV) and subcutaneous (SC) administration. A randomized open-label study, PrefHer, reported compelling pt preference for H SC (Pivot et al. \textit{Lancet Oncol} 2013; \textit{Ann Oncol} 2014), and a prospective observational study reported less societal cost and pt time associated with H SC vs H IV in Sweden (Olofsson et al. \textit{Breast} 2016), which may allow for earlier release of pts from hospital. To assess how this may translate to actual practice, we aimed to describe H SC and H IV use in a real-world setting and investigated a potential switch from one formulation to the other in the real world.

Methods
This observational, retrospective, longitudinal cohort study evaluated electronic medical records of adult female pts with a first incident diagnosis of EBC (neoadjuvant or adjuvant settings) and first use of H from 01/01/10–04/24/18 in three mid-size hospitals in Sweden (Sundsvall, Eskilstuna, and Kalmar). Data from first H administration (index date) until last recorded visit up to the day before metastasis (if any) were analyzed. Combination anticancer treatment was defined as any drug recorded from index date to index date +28 days. A switch between formulations was defined as any H administration using a formulation different from that given at the index date.

Results
Four hundred twenty-one pts received initial H (median age 60.2 years, range 23.3–88.5). Of these, 260 (61.8%) started treatment with H SC and 161 (38.2%) with H IV. After H SC was introduced in Nov 2013, use of H SC as the initial formulation increased from 72.7% in 2014 to 100% in 2017 (Table). Both H SC and H IV were mostly initiated with a combination IV chemotherapy e.g., a taxane (65.8% vs 74.5%, respectively). Some combination pertuzumab (F. Hoffmann-La Roche Ltd) was observed (2.3% vs 1.9%). Since 2013, 40 of 63 pts (63.5%) switched from initial H IV to H SC; ten (25.0%) switched back to H IV. Four of 260 pts (1.5%) switched from H SC to H IV; three (75.0%) switched back to H SC.

**Conclusion**

H SC quickly became the prevailing (practically exclusive) formulation for treatment of pts with HER2-positive EBC. Furthermore, most pts who started on H IV switched to H SC, while a minority switched from H SC to H IV. Most pts also received similar combination IV treatment (e.g., pertuzumab or chemotherapy) regardless of H formulation. Results are in line with pt preference for H SC in the PrefHer study, and the body of evidence that oncology units switch to SC formulations of biologics as an integral part of routine care.
PAM50 and CGH-array genomic characterization of HER2-equivocal breast cancers defined by the ASCO/CAP2013 recommendations and response to treatment

Edith Borcoman1, Carine Ngo1, Audrey Rapinat1, Fatoumata Simaga1, Odette Mariani1, Laetitia Fuhrmann1, Emmanuelle Jeannot1, Marick Laé1, Jean-Yves Pierga1, David Gentien1, Gaelle Pierron1, Pascale Morel2, Heather Ann Brauer2 and Anne Vincent-Salomon1. 1Institut Curie, Paris, Ile de France, France and 2Nanostring Technologies, Seattle, WA.

Background
HER2 breast cancer status determines patients' eligibility for targeted therapy. HER2 level of amplification is associated with a better response to anti-HER2 therapy (Arnould CCR 2007, Singer CCR 2017). Benefit of anti-HER2 therapy for equivocal cases remains debated.

Objectives
We aimed to better characterize HER2-equivocal breast cancers by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) according to 2013 ASCO/CAP guidelines using PAM50 gene expression-based molecular subtyping. We then investigated genome-wide copy number alterations of HER2-equivocal cases, assessing agreement between genomic alterations of the chromosome (chr) 17 and molecular subtypes.

Methods
PAM50 (nCounter assay; Nanostring) was performed on RNA from formalin-fixed paraffin-embedded samples of 40 HER2-equivocal cases. These cases were subsequently analyzed by Agilent 60-mer oligonucleotide microarrays for array-based comparative genomic hybridization (aCGH).

Results
The 40 HER2-equivocal cases were classified as Luminal B in 16 cases (40%), HER2-Enriched in 14 cases (35%), Luminal A in 9 cases (22.5%) and Basal-like in 1 case (2.5%) using PAM50.
By IHC, 34 cases (85%) were ER+, 24 (60%) were also PgR+, 26 (65%) were grade III and 33 (82.5%) showed a high Ki67 > 20%.
Using aCGH, 10 cases (25%) presented chr 17q large copy number gain, 10 (25%) showed segmental copy number gains including HER2, 9 (22.5%) showed HER2 amplification, one (2.5%) showed a large copy number loss and 10 cases (25%) didn't show any copy number alteration of the chr 17.
Out of the 14 PAM50 HER2-Enriched cases, only 5 (35.7%) showed HER2 genomic amplification (Table 1). Four HER2 amplified cases at the genomic level were classified as Luminal B (3 cases, Ki67 > 20%, ER+, PgR- by IHC) or Luminal A (1 case, Ki67<20%, ER+, PgR>10% by IHC) using PAM50, although these luminal B tumors presented strong correlation with the HER2-Enriched centroid. In total, 13 cases (32.5%) were discordant between molecular classification and genomic alteration status of the chr 17.
Among patients with early stage HER2-equivocal breast cancers (n=37), 2 received neo-adjuvant chemotherapy (5.4%), 25 received adjuvant chemotherapy (67.6%) and 2 received adjuvant trastuzumab (5.4%). With a median follow up of 5.8 years (3.8-6.9), one contralateral recurrence (2.7%), four metastatic recurrences (10.8%) and three deaths were observed (8.1%).

Conclusion
Using PAM50, the majority of HER2-equivocal cases were classified as Luminal tumors.
At the genomic level, HER2-equivocal cases harbored mostly chr 17 segmental or large copy number gains. These results emphasized the need of HER2 status genomic determination. In line with the new ASCO 2018 recommendations intending to decrease the number of cases considered as HER2 equivocal, we showed that these tumors were mainly HER2 not amplified, ER positive and grade 3. There is no evidence of benefit of anti-HER2 therapy in these cases.

Care 001: multi-center randomized open-label phase II trial of neoadjuvant trastuzumab emtansine (T-DM1) in combination with lapatinib and nab-paclitaxel compared with paclitaxel, trastuzumab and pertuzumab in HER2-neu over-expressed breast cancer patients (TEAL study)

Sarah L Creamer¹, Tejal A Patel¹,², Joe E Ensor¹,², Angel A Rodriguez¹,², Polly A Niravath¹,², Jorge G Darcourt¹,², Virginia G Kaklamani³, Jane L Meisel⁴, Xiaoxian Li⁵, Jing Zhao⁵, John G Kuhn³, Roberto R Rosato², Wei Qian², Anna Belcheva¹, Toniva Boone¹ and Jenny Chang¹,². ¹Houston Methodist Cancer Center, Houston, TX; ²Houston Methodist Research Institute, Houston, TX; ³The University of Texas Health Science Center, San Antonio, TX; ⁴Winship Cancer Institute Emory University School of Medicine, Atlanta, GA and ⁵Affiliated Hospital of Qingdao University, Qingdao, China.

Background: We conducted a multicenter, randomized open-label phase II neoadjuvant study of trastuzumab-emtansine (T-DM1), Lapatinib (L) and Nab Paclitaxel (Nab-P) compared to standard of care (SOC) Paclitaxel (Pac), Trastuzumab (T), and Pertuzumab (P) in patients with HER2 over-expressed breast cancer.

Methods: Patients in the experimental arm received a biologic window of targeted therapies alone for 6 weeks (T-DM1 and L) followed by T-DM1 3.0 mg/kg Q3W, L 750mg oral daily and Nab-P 80 mg/m² weekly (QW) X 12 weeks. Patients in SOC arm received targeted therapies alone for 6 weeks (T and P) followed by Pac 80mg/m²QW, T 2mg/kg QW, and P 420mg Q3W X 12 weeks. The primary objective was to evaluate the proportion of patients with residual cancer burden (RCB) 0 or 1. Key secondary objectives included correlative assessments of PIK3CA mutations, PTEN expression, and HER2 subtypes which are being reported.

Results: Thirty of the 33 enrolled patients were evaluable. Patient demographics were well balanced. HER2 subtypes and altered PIK3CA (low PTEN or PIK3CA mutations) pathway were not statistically different between both arms. We have previously reported that all patients achieved RCB 0 & I in the T-DM1, L and Nab-P arm, compared to SOC (100% vs. 62.5%, p 0.0035). In the SOC arm, the 6 week change in tumor size on breast MRI during targeted biologic window treatment is significantly different between the responders and non-responders based on two-sided Wilcoxon rank-sum test (p =0.0065).

Sixteen patients total were present in standard of care arm but 5 had incomplete imaging data.

Consistent with literature, among ER positive patients treated with SOC, PTEN low expressers were less likely to respond (0%, 0 of 2) than PTEN high expressers (67%, 2 of 3). In the experimental arm, all patients responded regardless of PTEN. There was only 1 PIK3CA mutation on the experimental arm where all responded.

Conclusions: TDM1 plus L and Nab-P therapy was well tolerated with noteworthy responses in all patients, including in PTEN low expressers. Change in tumor size at 6 weeks of biologic therapies was significant between responders and non-responders and can be evaluated as a surrogate for future studies.
Real world experience of the medical and surgical management of HER2 positive early breast cancer treated with neoadjuvant trastuzumab and pertuzumab via the NHS England cancer drug fund

Benjamin Hall1,2, Ajay Bhojwani1,2, Helen Innes2, Eliyaz Ahmed2, Joanne Cliff2, Zaf Malik2, Julie O'Hagan2, Shaun Tolan2, Alison Hall2, Khizar Hayat2, Douglas Errington2, Farida Alam2, Nicky Thorp2, Helen Flint2, Andrea Law2, Helen Wong2, Susan O'Reilly2, Richard Jackson1, Silvia Cicconi1 and Carlo Palmieri1,2. 1University of Liverpool, Liverpool, Hammersmith and Fulham, United Kingdom and 2Clatterbridge Cancer Centre NHS Foundation Trust, Liverpool, United Kingdom.

Background: Studies of neoadjuvant (NA) dual HER2 blockade with trastuzumab (T) and pertuzumab (P) in combination with chemotherapy (CT) for early breast cancer (BC) have reported pathological complete response (pCR) rates of 39 to 62%. These studies also report manageable toxicity with diarrhoea reported in up to 73% of cases. To date no real-world studies have explored the efficacy and toxicity of this treatment. The objective of this study was to describe the medical and surgical management of women treated with neoadjuvant T-P in combination with CT (NAT-P-CT). As well as to determine the efficacy and toxicity of NAT-P-CT in the context of a routine UK NHS clinical practice.

Methods: Patients with HER2+ BC treated neoadjuvantly with T-P accessed via the NHS England Cancer Drug Fund (CDF) at the Clatterbridge Cancer Centre NHS Foundation Trust between October 2016 and January 2018 were retrospectively identified. Clinico-pathological information, treatment data, nurse led toxicity review and echocardiographic were reviewed. Data lock was 19th June 2018.

Results: 78 female patients were identified with a median age of 50 years (IQR: 44.4-60.2). At diagnosis: median tumour size 30mm (23.0-47.5mm), 62% (48/78) were LN positive & 56% (44/78) ER+. CT regimens: 81% (63/78) FEC-DHP of these 30% (19/63) switched to weekly paclitaxel (wP). or nab-paclitaxel; 5% (4/78); AC/EC-DHP; 9% (8/78) TCHP with 13% (1/8) switched to wP. At time of analysis, 88% (69/78) had undergone definitive surgery. Surgical details: Breast: 52% (36/69) mastectomy & 48% (33/69) WLE, Axillary management: 51% (35/69) axillary dissection (Ax Dx) & 49% (34/69) sentinel node biopsy (4 performed prior to NA treatment). 91% (32/35) of those undergoing Ax Dx were LN+ at presentation, of these 59% (19/32) had no evidence of axillary involvement at surgery. pCR rate (ypT0/is, N0) was 46% (32/69) [pCR by HR: ER+ 43% (21/49) & ER- 55% (11/20). pCR for 20 patients switched to wP was 60% (12/20). 7% (5/69) achieved pCR in the breast alone (in these LN status ITCx1, micrometsx3 & macrometsx1). Of the 54% (37/69) with residual breast tumour median size was 13mm (1-22mm). Toxicity Data: Ejection fraction (EF) did not decline beyond 10% of baseline in any patients. Diarrhoea (any grade) occurred in 74% of cases, and CTCAE grade 3-4 toxicity occurring in >2% of patients: diarrhoea, fatigue, and infection. Updated analysis regarding pCR rate and toxicity, as well as initial outcome data will be presented.

Conclusion: These results (1) confirm the efficacy of NA T-P in a real world population; (2) support the use of NA wP; (3) indicate significant proportion of patients axilla are downstaged & (4) reveal diarrhoea rates in keeping with the literature. Currently, NHS England rules do not allow wP to be used routinely in NA setting with T-P this should be reviewed in light of these data and those of the BERENICE study. Measures to identify patients who can avoid axillary dissection as well as to mitigate diarrhoea should be considered.
Outcomes of real-world use of eribulin plus trastuzumab for HER2-positive metastatic breast cancer

Sarah S Mougalian1, Ronda Copher2, Lindsay McAllister3, Janna Radtchenko3, Edward C Wang2, Mary Broschous3, Hsing-Ting Yu3 and Jonathan Kish3. 1Yale Medical Center, New Haven, CT; 2Eisai Inc., Woodcliff Lake, NJ and 3Cardinal Health Specialty Solutions, Dallas, TX.

Background
Eribulin mesylate is approved for the treatment of metastatic breast cancer (mBC) after two prior chemotherapy regimens including an anthracycline or a taxane in either the metastatic or adjuvant setting. Eribulin in combination with trastuzumab (E+T) has demonstrated tolerability and anti-tumor activity in phase I and II trials but is not FDA-approved for the treatment of HER2-positive mBC. Case series and retrospective research have noted the use of E+T in clinical practice. We sought to describe patient characteristics and long-term outcomes of treatment with E+T for HER2-positive mBC patients treated outside of clinical trials in the US.

Methods
US-based community oncologists from an open network of over 7,000 oncologists, hematologists, and urologists were invited to participate in identifying HER2-positive mBC patients treated with E+T between 01/01/11 and 12/31/13 outside of clinical trials. Data were collected from 03/18/2016 until 09/01/2016. Providers completed an electronic case report form (CRF) by abstracting data on disease characteristics, treatment patterns, disease response (per provider assessment), adverse events (Aes), and date of death. Duration of treatment and overall survival (OS) were calculated from the initiation of the E+T regimen. The target sample size was 60 patients and patients were selected according to resource available for chart data abstraction.

Results
Twenty-three providers submitted CRFs for 62 total patients. After data collection, 59 of 62 submitted records were validated for analysis. At mBC diagnosis, 69.4% of patients were ER/PR negative and 42.4% of patient had de novo stage IV disease. At initiation of E+T, the median age was 57 years and 81.4% were ECOG-OS 0/1. Mean length of follow-up from the initiation of any therapy was 33.6 months. Twenty-two (37.3%) patients initiated E+T as their first- or second-line of treatment; those remaining were in third-line or greater. At initiation of E+T, 72.8% of patients had prior treatment with trastuzumab in combination with chemotherapy, 25.4% had prior trastuzumab in combination with pertuzumab and chemotherapy, and 16.9% had received TDM-1. Mean duration of E+T treatment was 5.2 months (SD=2.4). A response (complete [CR] or partial [PR]) was recorded by the providers for 64.4% of patients (not independently verified). The most common Aes reported were fatigue (67.8%), weakness (50.8%), decreased appetite (28.8%), decreased hemoglobin (27.1%), peripheral neuropathy (25.4%), and neutropenia (18.6%). At the end of the study period, 34 patients (57.6%) were deceased; the median OS from the initiation of E+T was 23.9 months (95% CI: 17.8-30.4).

Conclusions
In a small cohort of patients treated with E+T in the community setting, the observed response rate of 64.4% (CR+PR) was comparable to that of a prior phase II trial of E+T which reported an ORR with first-line E+T of 71.2% overall, 77.4% among T-naïve and 61.9% in T-pretreated patients. Further research is warranted to examine the tolerability and efficacy of E+T for metastatic HER2-positive breast cancer patients in different treatment settings.
Clinical characteristics of prolonged and exceptional responders to HER2 targeted therapy in metastatic breast cancer

Zachary W Veitch¹,², Philippe Bedard¹, Patricia A Tang³, Jessica L Conway³, Domen Ribnikar¹, Hamzeh Albaba¹, Karen King⁴, Sasha Lupichuk² and David Cescon¹. ¹Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada; ²Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada; ³Princess Margaret Cancer Centre, University of Toronto, Edmonton, AB, Canada and ⁴Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada.

Background: The evolution of HER2 targeted therapies continue to improve outcomes for patients with HER2-positive (HER2+) metastatic breast cancer (MBC). Although most patients progress after a relatively short duration, some experience prolonged (PRO) or exceptional (EXC) response to anti-HER2 therapy. However, these are usually described in single case-reports, with larger cohorts being poorly characterized in the literature.

Objectives: To evaluate the clinical characteristics of HER2+ MBC patients experiencing prolonged or exceptional response to HER2 targeted antibody (Ab) therapy.

Methods: Patients receiving HER2 Ab therapy for HER2+ MBC at Princess Margaret Cancer Centre in Ontario, or in the province of Alberta (AB), Canada were evaluated. HER2 therapies were categorized by treatment era. Dates were selected based on provincial approval(s) of Ab therapies and included: chemotherapy plus trastuzumab (CT) for 2005-2013; and taxane plus trastuzumab-pertuzumab (THP), or trastuzumab-emtansine (TDM1) for 2012-2016. Total time on HER2 therapy (without treatment switch) was recorded regardless of treatment line. Patients were then selected using median duration of response (MDR) seen in respective phase II/III clinical trials and identified as having a PRO (2 x MDR) or EXC (3 x MDR) response. Clinical characteristics (ie: pathology, survival, treatment regimen/duration, sites of metastatic disease) and oncologist/radiologist reported or estimated best response (complete [CR] or partial [PR] response, or stable disease [SD]) was collected. Descriptive statistics, Kaplan-Meier method (survival) and, one-way ANOVA with post-hoc Tukey (comparative) were used.

Results: From 2005-2013, 1,830 patients (PMCC, n=651 AB, n=1179) received CT. During 2012-2016, 394 patients (PMCC, n=70; AB, n=324) received THP, and 179 (PMCC, n=40; AB, 139) received TDM1. Selection of PRO (CT=18.2 months [mths]; THP=40.4 mths; TDM1=25.2 mths) and EXC (CT=27.3 mths; THP=60.6 mths; TDM1=37.8 mths) responders using MDR criteria identified 75 (4%) patients as having a PRO (n=20) or EXC (n=55) response to CT. In the THP cohort, 35 (9%) patients had a PRO (n=33) or EXC (n=2) response, whereas in TDM1, 20 (11%) patients had a PRO (n=18) or EXC (n=2) response. Evaluation of best response for historically first-line CT (CR=30%, PR=45%, SD=25%) and current standard of care THP (CR=31.4%, PR=42.9%, SD=25.7%) showed high rates of PR and CR. Lower rates of CR were seen with TDM1 (CR=5%, PR=55%, SD=40%). In the CT cohort, more patients with a CR vs SD were ER/PR-negative (p<0.05); also more CT patients with a CR vs PR (p<0.05) or CR vs SD (p<0.01) were still alive. Median PFS was higher in the CT (PFS=3.0 years, 95%CI: 2.07-3.93;) than TDM1 cohorts (PFS=2.4 years, 95%CI: 1.80 – 2.98), and not reached in the THP cohort.

Conclusion: Small numbers of patients experience a PRO or EXC response to HER2 Ab therapies. Patients treated in the first-line setting are more likely to experience a CR. Patients treated with CT having a CR are more likely to be ER/PR-negative and have improved survival. Further studies are ongoing.
Changes in patient, tumor, and treatment characteristics over time in first-line trastuzumab plus taxane (paclitaxel/docetaxel) arms in HER2-positive metastatic breast cancer trials

Tanja Badovinac Crnjevic¹, Eleonora Restuccia², Francesca Michielin¹, Jennifer Eng-Wong² and Eveline Nüesch¹. ¹F. Hoffmann-La Roche Ltd, Basel, Switzerland and ²Genentech Inc., South San Francisco, CA.

**Background:**
A retrospective analysis showed improved progression-free survival and consistent underestimation of trastuzumab (H) + taxane (T) efficacy assumptions in first-line (1L) human epidermal growth factor receptor 2 (HER2)-positive metastatic breast cancer (MBC) trials over time (ISCB 2016). We evaluated changes in baseline and treatment characteristics and the safety profile of H+T in 1L HER2-positive MBC trials conducted during 1995–2015.

**Methods:**
Trial-level data on patient, tumor, and treatment characteristics and safety profiles in H+T arms of 15 randomized trials were extracted from published data and clinical study reports. Characteristic and safety profile changes over time were explored by weighted regression; relevance was assessed by F-test.

**Results:**
Patient and tumor characteristics were generally stable over time. We observed relevant changes in types of adjuvant therapy used. Serious adverse events (SAEs) and study withdrawals due to Aes decreased over time; rates of treatment discontinuation due to Aes increased.

**Conclusions:**
In 1L HER2-positive MBC trials, the percentage of patients who received adjuvant chemo-, hormonal, and radio-therapy decreased from 1995 to 2015. These changes in treatment patterns suggest a shift towards a higher percentage of patients with *de novo* metastatic vs recurrent disease in 1L MBC trials over time. Adjuvant H use increased following approval in 2005 as expected. While SAEs decreased over time, no firm conclusions on safety management can be made.
Real world evidence of neoadjuvant treatment based on dual blockade with pertuzumab plus trastuzumab for early HER2+ breast cancer: The NeoPETRA study

José Ignacio Chacón¹, Cristina Saura², Eva Ciruelos³, José Luis Alonso⁴, Pilar de la Morena⁵, Marta Santisteban Eslava⁶, Isabel Gallegos⁷, Alicia de Luna⁷, Elsa Dalmau⁹ and Santiago González-Santiago¹⁰. ¹Hospital Virgen de la Salud, Toledo, Spain; ²Hospital Universitario Valld’Hebron, Vall d’Hebrón Instituto de Oncologia (VHIO), Barcelona, Spain; ³Hospital Universitario 12 de Octubre, Madrid, Spain; ⁴Hospital Universitario Virgen de la Arrixaca, Murcia, Spain; ⁵Hospital General Universitario J.M. Morales Meseguer, Murcia, Spain; ⁶Clínica Universidad de Navarra, Pamplona, Spain; ⁷Hospital General de Segovia, Segovia, Spain; ⁸Hospital Clínico San Carlos, Madrid, Spain; ⁹Parc Taulí Sabadell. Hospital Universitari, Barcelona, Spain and ¹⁰Hospital San Pedro de Alcántara, Cáceres, Spain.

Background: Evidence from clinical trials supports the neoadjuvant use of pertuzumab and trastuzumab with chemotherapy to improve the pathologic complete response (pCR) in early HER2+ breast cancer (BC), but information on the efficacy of this combination in the clinical practice setting is still limited. In order to widen its real-world data (RWD), we conducted an observational study to determine the pCR rate obtained in routine clinical practice.

Methods: This was a multicenter, retrospective, observational study in patients (pts) with early HER2+ BC who received neoadjuvant therapy based on dual blockade with pertuzumab and trastuzumab. All data were retrospectively collected from pts medical charts. The primary study objective was the total pCR rate (ypT0/is ypN0). Secondary objectives included patient characteristics, neoadjuvant treatment patterns with the dual blockade, surgery types, breast pCR rate (ypT0is), and neoadjuvant safety profile.

Results: Two hundred and forty-three evaluable pts treated in Spain between November 2013 and September 2017 were enrolled between October 2017 and February 2018 (median age [range] 51.7 [44.7-60.2] years; postmenopausal 47.7%; ECOG 0/1 88.9/10.6%; stage II/III tumors 54.3/28.7%; hormone receptor-positive 62.4%). The most common neoadjuvant chemotherapies used were taxanes+anthracyclines (n=180, 74.1%), platinum-based chemotherapies (n=35, 14.4%), and taxanes (n=27, 11.1%). Response rates (radiologic/clinical assessments) before surgery were: complete response 62.1% (n=151), partial response 33.3% (n=81), stable disease 4.1% (n=10), and non-evaluable 0.4% (n=1). Breast-conserving surgery (tumorectomy/lumpectomy and quadrantectomy) was performed in 57.8% (n=133) pts and not conserving (simple, radical and modified radical mastectomy) in 42.2% (n=97). The total pCR was 66.4% and breast pCR was 67.6%. Total pCR in the breast was achieved by 80.7% (n=67) hormone receptor-negative and 56.3% (n=76) hormone receptor-positive pts (statistically significant differences; p<0.001). According to neoadjuvant treatment, total pCR in the breast was achieved by 71.0% (n=120) taxanes+anthracyclines, 48.6% (n=17) platinum-based chemotherapies, and 59.3% (n=16) taxanes users (statistically significant differences; p=0.028). Sixty-three (35.0%) pts experienced at least one adverse reaction (AR) to pertuzumab/trastuzumab+taxanes+anthracyclines (grade 3 ARs: asthenia 0.6%, diarrhea 2.2%, febrile neutropenia 1.1%, and neutropenia 1.1%; grade 4 AR: neutropenia 0.6%), 3 (8.6%) to pertuzumab/trastuzumab+platinum-based chemotherapies, and 22 (11.1%) to pertuzumab/trastuzumab+taxanes (grade 3 AR: diarrhea 3.7%).

Conclusions: This is the first, to the best of our knowledge, multicenter observational study to determine the pCR rate obtained in routine clinical practice in Spain. Results obtained from it have been remarkable: neoadjuvant therapy based on dual blockade with pertuzumab and trastuzumab for HER2+ BC in the routine clinical practice setting enabled the achievement of total pCR rates over 66%, which are even higher than those obtained in previous clinical trials. In addition, this therapy has showed an acceptable safety profile, in line with previous assessments.
Impact of the line of treatment on progression-free survival in patients treated with T-DM1 for metastatic breast cancer

Francois P Duhoux¹, Victoria Dufour², Aline van Maanen³, Martine Berliere¹, Donatienne Taylor⁴ and Jean-Luc Canon⁵. ¹King Albert II Cancer Institute, Cliniques Universitaires Saint-Luc and Institut de Recherche Expérimentale et Clinique (Pôle MIRO), Université Catholique de Louvain, Brussels, Belgium; ²Université Catholique de Louvain, Brussels, Belgium; ³Statistical Support Unit, King Albert II Cancer Institute, Cliniques Universitaires Saint-Luc, Brussels, Belgium; ⁴CHU UCL Namur, Site Sainte-Elisabeth, Namur, Belgium and ⁵Grand Hôpital de Charleroi, Charleroi, Belgium.

Background Trastuzumab emtansine (T-DM1) is a monoclonal antibody targeting human epidermal growth factor receptor 2 (HER2) receptors, conjugated with a cytotoxic component (a microtubule inhibitor). It is indicated as second-line treatment for HER2-positive metastatic or unresectable locally advanced breast cancer, after progression on trastuzumab and a taxane-based chemotherapy.

In HER2-negative metastatic breast cancer, progression-free survival (PFS) declines with each line of therapy, while patients with HER2-positive disease receive the most lines of chemotherapy and the longest duration for every line. We wished to investigate whether the line of treatment in which T-DM1 is administered has an impact on PFS. We also wished to explore whether prior treatment with capecitabine / lapatinib or pertuzumab had an impact on PFS, as none of the patients included in the registration trial had received these treatments before their inclusion in the trial.

Methods This is a multicenter retrospective study performed in 3 Belgian institutions. All patients received T-DM1 for HER2 positive metastatic or unresectable locally advanced breast cancer. The primary outcome was PFS with T-DM1, defined as the period between the first administration of T-DM1 and the first radiological or clinical assessment demonstrating progression of the disease.

Results We included 51 patients. One patient had to be excluded from the analyses because she no longer had HER positive disease. The median PFS was 9.01 months. The line of treatment in which T-DM1 was administered had no influence on PFS (hazard ratio 0.976, CI95 0.835-1.142).

There was no statistically significant difference in PFS between patients who had not received capecitabine / lapatinib before T-DM1 and those who had (9.11 vs 8.91 months, p-value 0.466).

Median PFS was 10.07 months when T-DM1 was administered prior to pertuzumab, and 5 months when administered after pertuzumab. Patients who received pertuzumab before T-DM1 thus tended to exhibit a shorter PFS. However, this difference is not statistically significant (p-value 0.096).

Conclusions Unlike with conventional chemotherapy, the line of treatment in which T-DM1 is administered does not influence PFS in metastatic breast cancer patients.
A multi-scale mathematical model of combination targeted and cytotoxic therapy to evaluate treatment response in HER2+ breast cancer

Angela M Jarrett1, Alay Shah1, Meghan J Bloom1, Thomas E Yankeelov1 and Anna G Sorace1. 1The University of Texas at Austin, Austin, TX.

Introduction: We have previously established a tissue scale mathematical model with 5 coupled, ordinary differential equations (ODEs) describing the longitudinal relationship of vasculature, hypoxia, necrosis, immune infiltration, and tumor growth in a preclinical model of human epidermal growth factor receptor 2 positive (HER2+) breast cancer undergoing trastuzumab treatment. The purpose of this study is to expand this model to multiple scales (tissue and cellular) and to explicitly include the effects of combination trastuzumab-paclitaxel therapy as measured by time-resolved microscopy of in vitro HER2+ breast cancer cells. This requires interlacing experimental data and additional ODEs at the cellular scale to incorporate drug dynamics within the tissue scale model for overall tumor growth. An integrated multi-scale mathematical-experimental approach bridging in vivo and in vitro experimental data has potential to elucidate the optimal strategies for combination therapy for HER2+ breast cancer.

Experimental: In vitro data was collected to longitudinally evaluate BT474 HER2+ human cancer cells growth when treated with trastuzumab (25-50 ug/ml) and/or paclitaxel (10-250 nmol/L) measured by time-resolved microscopy. Changes in confluence before and after treatment are recorded every 3 hours over the course of 7 days. Ongoing studies are quantifying the change in confluence for these cells with alternating dosing and timing of the two therapies.

Modeling: The in vivo, tissue-scale model parameters were calibrated using mean and 95% confidence intervals of tumor volume from caliper measurements, vasculature and hypoxia from imaging data, and necrosis from histology. The in vitro scale of the model is calibrated with confluence data for controls to define intervals for growth rates and carrying capacities. Experimental results for single drug applications are used to estimate cell death, and data from combinations of both the targeted anti-HER2 therapy and cytotoxic therapies provide estimates of synergistic drug effects. After calibration of parameters, the two scales of the model are coupled via the tumor volume and vasculature components to simulate the effects of combination therapy in vivo.

Results and Discussion: The confluence data shows that trastuzumab dosing in combination with paclitaxel results in the greatest reduction in tumor cells than either drug alone (p < 0.05), and there are distinct differences in alternating the order and timing of these drugs. Further, preliminary results show that the model's in vitro scale equations can be calibrated with the available longitudinal data. As dosing of combination therapy in vitro provides the opportunity to quantify the effects of combination therapy that would not be feasible to collect in an in vivo setting, our aim is to generate experimentally testable predictions for improved combination therapy in vivo with our multiscale model. This is an important step for future clinical translation to provide temporal guidance of standard-of-care, combination therapies, potentially leading to significantly improved anticancer response in HER2+ breast cancer.

Clinical analysis of lapatinib in combination with capecitabine versus continued use of trastuzumab in advanced HER2-positive breast cancer patients with trastuzumab-resistance

Fan Yang¹, Yongmei Yin¹ and Zefei Jiang². ¹The First Affiliated Hospital of Nanjing Medical University, Nanjing, China and ²The First Affiliated Hospital of Nanjing Medical University, Beijing, China.

Purpose
Trastuzumab-refractory patients will derive clinical benefit from further anti-HER2 therapy. It is unclear whether we should adopt empiric continuation of trastuzumab beyond progression. We evaluate the efficacy and safety of lapatinib plus capecitabine (LC or LX) versus trastuzumab plus chemotherapy in patients with HER-positive metastatic breast cancer who were resistant to trastuzumab.

Patients and methods
We retrospectively analyzed breast cancer patients linked to detailed demographic, treatment, outcome data who began the regimen of lapatinib plus capecitabine (LC or LX) or trastuzumab beyond progression (TBP) at eight hospitals between May 2010 and October 2017. Among those, 299 patients had received TBP and 255 were treated with LX. The clinicopathologic parameters explored included age, hormone receptor status, metastatic sites, primary or acquired trastuzumab resistance, previous treatment. Primary endpoint was evaluation of progression-free survival (PFS), key secondary endpoints were overall response rate (ORR), clinical benefit rate (CBR).

Results
Among 554 patients who had developed resistance to trastuzumab, 255 in the LX group and 299 in the TBP group. The median PFS was 6.77 months in the LX group compared with 5.6 months in the TBP group (hazard ratio 0.7955; 95% CI, 0.6632 to 0.9542; log-rank P = 0.014). In the primary resistant patients, the median was significantly increased from 4.3 months for TBP to 6.8 months for LX (HR = 0.4986; 95% CI, 0.3632 to 0.6844; P < 0.001). In the secondary resistant patients, no significant difference was observed (median PFS: 6.6 months for LX vs 6.3 months for TBP, P = 0.883). The central nervous system progression rate during treatment was 5.9% in LX group and 12.5% in TBP group, respectively (P = 0.018). The most frequent grade III-IV AEs were diarrhoea (5.1%), hand–foot syndrome (10.2%) in LX group, and ALT/AST increased (9.1%) and neutropenia (6.4%) in TBP group.

Conclusion
The combination of lapatinib and capecitabine has shown a prolonged PFS compared with TBP in patients who had progressed on trastuzumab.
Consensus and disagreement among experts for treatment of patients with HER2+ early-stage breast cancer suggests unmet need for online decision support tool

Frankie Ann Holmes¹, Kristen M Rosenthal², Sara Hurvitz³, Mark D Pegram⁴, Denise A Yardley⁵, Kevin L Obholz⁴ and Joyce O'Shaughnessy⁶. ¹Texas Oncology, US Oncology, Houston, TX; ²Clinical Care Options, LLC, Reston, VA; ³David Geffen School of Medicine at UCLA, Los Angeles, CA; ⁴Stanford Cancer Institute Stanford University, School of Medicine, Stanford, CA; ⁵Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN and ⁶Baylor University Medical Center, Texas Oncology, US Oncology, Dallas, TX.

Treatment (tx) choices for HER2+ early stage breast cancer (EBC) have become increasingly complex. Clinicians and patients must decide 1) which chemotherapy and HER2-targeted agents to use, 2) the sequence of surgery and chemotherapy: either neoadjuvant (neoadj) or adjuvant (adj) tx, and 3) whether to shorten or extend maintenance HER2-targeted tx. As tx options expand, so does the need for online decision aids. One online decision support tool was developed in 2015 to provide specific tx recommendations for pts with EBC and showed that community healthcare providers (HCPs) did not consistently align with experts for neoadj or adj tx of many pts with EBC (SABCS 2015 Abs P5-09-04).

This study includes analysis of neoadj and adj tx practice patterns of 5 breast cancer experts based on their tx recommendations for 270 unique HER2+ EBC case scenarios made for development of a 2018 online decision tool. We aim to compare these recommendations with the intended treatment of clinicians using the tool.

**Results**

Experts agree on neoadj tx approaches: initial surgery, no neoadj tx for pts with cT1a/b N0 tumors; neoadj tx before surgery for pts with ≥cT2 or N+ tumors. There was disparity among experts for pts with cT1c N0 disease: 3 experts recommend neoadj TCH±P and 2 recommend proceeding directly to surgery.

Experts generally recommend adj TCHP for pts with stage II N+ or higher HER2+ EBC who did not receive neoadj tx. In addition, 5/5 experts would consider extended adj tx with neratinib for these pts if HR+ and 2/5 experts would also consider neratinib if HR–.

In pts who received neoadj chemo+HER2 tx, post-surgery management depends on response to neoadj tx. For pts with pCR, 5/5 experts generally agree on continuing H+P if both were given as neoadj tx or H alone if only H given as neoadj tx for a total of 1 yr of anti-HER2 Ab tx and 2/5 experts would consider extended adj tx with neratinib for HR+ disease. For pts with residual disease, experts would recommend continuing H+P if both were given as neoadj tx and most would add P for subsequent adj tx if H alone was given to complete a total of 1 yr of anti-HER2 Ab tx (Table1). All experts would consider extended adj tx with neratinib for HR+ disease and 3/5 experts would also consider neratinib for HR– disease. None of the experts recommended less than 12 mos of adj HER2-targeted tx.

We will present analyses of cases entered into our online tool and detailed comparisons of expert and the intended treatment of clinicians using the tool.

**Conclusions**

Practice patterns are changing rapidly and are more complex in response to the evolving treatment landscape for HER2+ EBC. This analysis highlights several areas of expert consensus; however, disparities remain for select cases. The current tool addresses an unmet medical need for expert-led evaluation of HER2+ EBC tx choices and warrants further investigation.

**Expert Recommendations: Initial Adj HER2 Ab Tx After Neodj Tx With H Alone**

Therapy landscape of patients with metastatic, HER2 positive breast cancer - Data from the real world breast cancer registry PRAEGNANT (NCT02338167)

Purpose:
This analysis describes comprehensive real-world data concerning the use of anti-HER2 therapies in HER2 positive metastatic breast cancer (MBC). Specifically, it describes the therapy patterns of treatments with trastuzumab (TZM), pertuzumab+trastuzumab (PTZ/TZM), lapatinib (LAP) and trastuzumab emtansine (T-DM1).

Methods:
The PRAEGNANT study is a real-time, real-world registry for patients with MBC. Patients can be registered for PRAEGNANT at any time during the course of their metastatic disease and are followed up until death. All therapy lines are documented. This analysis presents the utilization of anti-HER2 therapies as well as therapy sequences.

Results:
Of 1936 patients within PRAEGNANT at the time of database closure 451 were HER2 positive (23.3%). Within the analysis set (417 patients after an unilateral breast cancer diagnosis), of which 53% were included in PRAEGNANT in the 1st line setting, 241 were treated with TZM (58%), 237 with PTZ (57%), 85 with LAP (20%) and 125 with T-DM1 (30%) during the course of their therapies. The sequence PTZ/TZMâT-DM1 was given to 51 patients (12%). Worse ECOG, negative hormone receptor status, and visceral or brain metastases were associated with a more frequent use of this therapy sequence. Most patients received T-DM1 after a therapy with pertuzumab.

Conclusions:
Both novel therapies (PTZ/TZM and T-DM1) are utilized in a high proportion of HER2 positive breast cancer patients. As most patients receive T-DM1 after pertuzumab real world data might help to understand whether this sequence has similar efficacy like in the approval study.
Clinical and pathological features of breast cancer with 'polysomy' of Chromosome 17

Hongxia Sun¹, Hui Chen¹, Bora Lim¹ and Aysegul A Sahin¹. ¹The University of Texas, M. D. Anderson Cancer Center, Houston, TX.

Background: Anti-HER2 therapy is a standard of care for patients with HER2+ breast cancer. HER2 status is routinely evaluated using immunohistochemical stain and/or florescence in situ hybridization (FISH). Interpretation of FISH results may be challenging in tumors with 'polysomy' of chromosome 17 ('polysomy17'), which is defined by increased chromosome enumeration probe 17 (CEP17) signal number. There is evident that 'polysomy17 might account for anti-HER2 therapy response in breast cancer (BC) with normal HER2/CEP17 ratio. This study aims to study the clinical and pathological features of BC with 'polysomy17'. Method: Primary BC were selected based on elevated CEP17 count (≥3.0) in HER2 FISH performed at MD Anderson Cancer Center between April 2014 and March 2018 (n=385). Patient charts were reviewed for detailed clinical and pathological features. These cases were further divided into four groups according to HER2/CEP17 and HER2 copy number, based on ASCO-CAP guidelines: group 1 (HER2+) – HER2/CEP17≥2.0, HER2 copies≥4.0; group 3 (HER2+) – ratio<2.0, HER2 copies≥6.0; group 4 (HER2 equivocal) – ratio <2.0, HER2 copies ≥4.0 and <6.0; group 5 (HER2-) – ratio<2.0, HER2 copies<4.0. Chi-square tests were performed to study the difference of these characters. Results: In comparison with groups 1 and 3, BC in groups 4 and 5 are more commonly seen in elder patients (p=0.001). Also, these tumors show higher pathological category (p<0.001) and higher rate of lymph nodes metastasis (p<0.05). The clinical and pathological features are summarized in [Table 1]. Conclusion: Understanding the clinical and pathological features of BC with 'polysomy17' may help clinically to choose patients who might be benefit from anti-HER2 therapy. Further study is to follow up the therapy response of those who received anti-HER2 treatment in this cohort of patients.

Clinical and pathological characteristics of breast cancer with 'polysomy' of chromosome 17

BAT8001, a potent anti-HER2 antibody-drug conjugate with a novel stable linker for the treatment of HER2-positive breast cancer

Weijia Tang¹, Xiaobin Deng¹, Ziqiang Ou¹, Jirong Gan¹, Qingfeng Dong¹, Binghua Tan¹, Li Lu¹, Bei Chen¹, Cai Bao¹, Shengfeng Li¹, Bert Thomas¹ and Jin-Chen Yu¹. ¹Bio-Thera Solutions, Ltd., Guangzhou, Guangdong, China.

Overexpression of HER2 occurs in approximately 20% of breast cancers and is associated with shortened survival. Trastuzumab emtansine (T-DM1), an anti-HER2 ADC, has shown efficacy in HER2-positive breast cancer patients and was approved by the FDA and EMA for advanced HER2-positive breast cancer. However T-DM1 causes grade 3 and 4 thrombocytopenia in up to 14.5% of patients as its major toxicity. The thrombocytopenia is likely caused by one of T-DM1’s catabolites and payload, DM1, indicating T-DM1’s linker can be cleaved. Here we adopted a novel noncleavable linker and created an anti-HER2 ADC, BAT8001, which is expected be efficacious in HER2-positive breast cancer and have a better side effect profile relative to T-DM1 due to the stability of BAT8001’s noncleavable linker. BAT8001 is internalized in HER2-positive cancer cells. It inhibits proliferation of HER2-positive tumor cells with IC50s of ~0.1 nM, similar to the potency of T-DM1. BAT8001 also induces apoptosis in HER2-positive cancer cells. In both cell-line and patient-derived mouse xenograft (PDX) models, BAT8001 demonstrates strong inhibition activity on tumor growth. For example, in a cell-line model of breast cancer (BT474), BAT8001 demonstrates potent activity with complete responses in all animals tested at the 15mg/kg dose level. Pharmacokinetics studies in monkey reveals BAT8001 has similar Cmax, AUC, and t1/2 as T-DM1. The major catabolite of BAT8001 is the Cys-linker-payload containing product. No free payload is observed. This compares favorably with T-DM1 where free DM1, T-DM1's payload, is one of the major catabolites. In a multiple dose toxicity study, BAT8001 had a NOAEL of 15 mg/kg versus 10 mg/kg for T-DM1. BAT8001 exhibits similar potency to T-DM1 on inhibiting HER2-positive cell proliferation and tumor growth, yet demonstrates better multiple dose toxicity than T-DM1. The improved toxicity profile of BAT8001 suggests that the novel noncleavable linker utilized in BAT8001 is more stable than the linker utilized in T-DM1. BAT8001 is very efficacious in cell-line xenograft models of breast cancer. The preclinical profile of BAT8001 warrants further development for the treatment of breast cancer and other HER2-positive cancers.
Treatment benefit of ribociclib + letrozole in patients with de novo disease and visceral metastases from the MONALEESA-2 study

Joyce A O'Shaughnessy¹, Carlos L Arteaga², Lowell L Hart³, Deborah L Lindquist⁴, Joseph T Beck⁵, D D Purkayastha⁶, Nicola Caria⁶ and Gabriel N Hortobagyi⁷. ¹Texas Oncology-Baylor Charles A. Sammons Cancer Center, Dallas, TX; ²Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN; ³Florida Cancer Specialists, Fort Myers, FL; ⁴Arizona Oncology, US Oncology, Sedona, AZ; ⁵Highlands Oncology Group, Fayetteville, AR; ⁶Novartis Pharmaceuticals Corporation, East Hanover, NJ and ⁷The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Ribociclib (ribo) + letrozole (LET) demonstrated efficacy and safety in first-line treatment of patients (pts) with hormone receptor–positive (HR+), HER2– advanced breast cancer (ABC). Most endocrine therapy (ET)–naive pts with de novo ABC respond to ET, but first-line monotherapy with ET or fulvestrant elicited only moderate efficacy in the FALCON study of pts with visceral metastases (mets). Visceral mets are associated with poor prognosis and may warrant novel treatment options in addition to ET. Here, we present clinical outcomes of treatment with ribo in pts with de novo ABC and visceral mets.

Methods: In the MONALEESA-2 study, postmenopausal women with HR+, HER2– ABC (N=668) were randomized (1:1) to receive either ribo 600 mg/d or placebo (3 wk on/1 wk off) + LET 2.5 mg/d (continuous). The primary endpoint was median progression-free survival (mPFS).

Results: All pts in this analysis (n=227) had de novo ABC; 108 pts had visceral mets (ribo, n=53; placebo, n=55). Baseline characteristics were similar between the ribo and placebo groups. The median follow-up time was 26.4 months. In pts with visceral mets, mPFS was significantly higher in the ribo group (30.3 months) than in the placebo group (14.1 months; hazard ratio, 0.52; 95% CI, 0.295–0.905; P=0.019). Rates of PFS in these pts in the ribo vs placebo group, respectively, were 76% vs 60% at 12 months and 60% vs 36% at 24 months. Among the pts with visceral mets, clinical benefit rate (CBR) was 79% vs 71% in the ribo vs placebo group, and overall response rate (ORR) in pts with measurable disease at baseline was 55% vs 46%, respectively. In pts without visceral mets (ribo, n=61; placebo, n=58), PFS rates in the ribo vs placebo group, respectively, were 87% vs 72% at 12 months and 66% vs 51% at 24 months. Safety results were consistent with the overall population, and responses were durable with ribo + LET irrespective of whether the pts had visceral or nonvisceral mets.

Conclusions: Clinical outcomes from this analysis of the MONALEESA-2 study are consistent with those of the overall population, and ribo + LET prolonged the mPFS and improved ORR and CBR in pts with de novo ABC with visceral mets vs placebo + LET.
Primary and secondary results of the pilot study.

Methods: A total of 10 sites within SOLTI network in Spain participated. DNA-sequencing of 56 cancer related genes was performed using FFPE tumor samples (primary or metastatic). Each clinical case was reviewed by a multidisciplinary advisory board (MAB), which recommended, in a prospective manner, potential experimental treatments, mainly in the context of clinical trials. The primary objective was to determine the success rate of matching a DNA alteration to an experimental drug or drug class. Secondary objectives included a comprehensive molecular characterization of tumor samples by PAM50 subtyping and quantification of protein expression levels by MASS-SPEC (70 proteins panel).

Results: 305 patients (pts) were screened from September 2014 to July 2017 and 260 (85.3%) were finally evaluated by the MAB. Pts characteristics were: mean age 54 years (29-80), ER+/HER2- (n=192; 74%), HER2+ (n=30; 11.5%) and TNBC (n=38; 14.5%). 163 primary tumors and 97 metastatic samples were profiled. Regarding the primary objective, 116 pts (45%) presented at least one mutation (range 1-6) that could be matched to a drug or drug class. Of these, 13 pts (11.2%) received therapy matched to their molecular profile according to the MAB recommendation and their follow-up is still on-going. No mutation was detected in 97 (37%) pts (WT), and 47 patients (18.1%) presented a mutation but no match was possible. The most common mutations were PIK3CA (34%); TP53 (22%), AKT1 (5%), ESR1 (3%) and ERBB2 (3%). Intrinsic subtype distribution in 177 samples was as follows: 34% Luminal A (n=60); 21% Luminal B (n=36); 13% HER2E (n=22); 19% Basal-like (n=34) and 13% Normal-like (n=23). Compared to primary tumors (n=110), the proportion of HER2-enriched disease in metastatic tumors (n=63) was significantly higher (6% vs 20%; p=0.005). Protein expression analysis was performed in 146 samples (94 primary and 57 metastasis). In 19 cases (13%), the outlier expression of some targetable proteins (FGFR1 [n=4, 2.7%], IGF1R [n=4, 2.7%], EGFR [n=1, 0.7%], CEACAM5 [n=6, 4.1%], IDO1 [n=2, 1.37%], TROP2 [n=2, 1.37%]) were identified. Of note, HER2 overexpression (>740 amol/µg) was observed in 4 HER2- cases. Finally, among WT tumors, 21% presented a potential drug-matched protein target.

Conclusions: Nationwide molecular screening in Spain is feasible. Nearly half of patients had tumors with mutation(s), mostly PIK3CA, that could be matched to a potential drug or drug class. PAM50 profile might be helpful to navigate towards a therapeutic decision making, although the MAB could not make any targeted-driven recommendation yet with this data. More clinical evidence is needed to use MASS-SPEC as a diagnostic tool.
Biomarker analysis of CDK 4/6 and endocrine pathways in hormone-receptor positive (HR+) advanced breast cancer (ABC) bone only disease patients: A joint analysis of PALOMA-2 and PALOMA-3 studies

Richard S Finn1, Nicholas C Turner2, Yuan Liu3, Hope S Rugo4, Sibylle Loibl5, Véronique Diéras6, Dennis J Slamon1, Fabrice André7, Karen Gelmon8, Angela DeMichele9, Sherene Loi10, Zhe Zhang11, Carla Gioretti12, Eric Gauthier13, Cynthia Huang Bartlett14 and Massimo Cristofanilli15. 1David Geffen School of Medicine at University of California Los Angeles, Santa Monica, CA; 2Royal Marsden Hospital and Institute of Cancer Research, London, United Kingdom; 3Pfizer Inc, San Diego, CA; 4University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; 5German Breast Group, Neu-Isenburg, Germany; 6Centre Eugène Marquis and Institut Curie, Rennes, France; 7Institut Gustave Roussy, Villejuif, France; 8British Columbia Cancer, Vancouver, BC, Canada; 9University of Pennsylvania, Philadelphia, PA; 10Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia; 11Pfizer Inc, La Jolla, CA; 12Pfizer Inc, Milan, Italy; 13Pfizer Inc, San Francisco, CA; 14Pfizer Inc, Collegeville, PA and 15Robert H. Lurie Cancer Center of Northwestern University, Feinberg School of Medicine, Chicago, IL.

Background: Palbociclib (PAL) in combination with endocrine therapy (ET) is a preferred treatment option for untreated and previously treated patients with hormone receptor–positive (HR+) human epidermal growth factor receptor 2 (HER2)–negative ABC. Patients with bone only disease could derive prolong disease control with single agent ET. Further understanding the predictive markers for sensitivity to ET alone and P+ET in both endocrine sensitive and resistant settings could help guide clinical treatment sequencing decision. We performed biomarker (BM) analysis of baseline tumor tissues in both PALOMA-2 (P2) and PALOMA-3 (P3) in bone only (BO) vs non-bone (NBO) only patients.

Methods: Postmenopausal women (N=666) with no prior systemic therapy for ER+/HER2-ABC were randomized 2:1 to receive PAL+LET or matching placebo (PBO)+LET in P2. In P3 women (N=521) who progressed on prior endocrine therapy were randomized 2:1 to receive PAL+ FUL vs matching PBO+FUL. All pts including those with BO disease had to consent to provide tumor tissues to participate the current study. EdgeSeq Oncology Biomarker Panel (HTG Molecular Diagnostics; Tucson, AZ) was used for mRNA profiling. Cox regression analysis was used to evaluate the association of BO disease with treatment effect as well as the association of gene expression with treatment effect in BO vs NBO pts.

Results: Treatment effect in the BM population from each study was consistent with that observed in the respective ITT population. In ITT population, BO disease was reported in 151 (23%) pts of P2 with mPFS 36.2mo PAL+LET arm (n=103) vs 11.2mo LET arm (n=48), HR=0.40 (0.26-0.62) and in 124 (24%) pts of P3 with mPFS 14.3mo PAL+FUL arm (n=86) vs 9.2mo FUL arm (n=38), HR=0.64(0.38-1.06). BO disease was reported in 107 (24%) pts in P2 and 81 (27%) pts in P3 BM population. In P2, longer mPFS was seen with PAL+ LET vs PBO+LET in BO vs NBO disease (30.6 mo vs 11.2 mo; HR=0.42 (0.25-0.69) in BO pts and 22.1 mo vs 13.8 mo HR=0.67 (0.52-0.88) in NBO pts) although the interaction effect was not statistically significant. Similar results were also observed in P3 with longer mPFS in PAL+FUL vs PBO+FUL in BO vs NBO disease (16.6 mo vs 11.2 mo HR=0.79 (0.40-1.56) in BO pts and 11.1mo vs 3.5 mo HR=0.47 (0.34-0.66) in NBO pts) with insignificant interaction effect. In both studies, BO pts had higher incidence of luminal A disease (BO vs NBO: P2=62% vs 47%; P3=54% vs 40%) and lower rate of luminal B disease (P2=19% vs 33%; P3: 26% vs 33%). In both studies, baseline ESR1, Cyclin E and CDK 4 gene expression level were comparable between BO vs NBO pts. Elevated CDK4 gene expression level was associated with resistance to LET in P2 and lower Cyclin E gene expression predicts the effect of PAL in P3.

Conclusion: mPFS was significantly prolonged in BO pts with the addition of PAL to ET. BO disease was more frequently associated with luminal A subtype in ABC setting. CDK4 expression level was similar to NBO disease pts but associated with resistance to single agent LET.
Ribociclib with a non-steroidal aromatase inhibitor and goserelin in premenopausal women with hormone receptor-positive, HER2-negative advanced breast cancer: MONALEESA-7 age subgroup analysis

Debu Tripathy1, Saul Campos-Gomez2, Yen-Shen Lu3, Fabio Franke4, Aditya Bardia5, Paul Wheatley-Price6, Felipe Melo Cruz7, Roberto Hegg8, Fatima Cardoso8, Anil Gaur10, Oliver Kong11, Ivan Diaz-Padilla12, Michelle Miller11 and Sara Hurvitz13. 1The University of Texas MD Anderson Cancer Center, Houston, TX; 2Centro Oncológico Estatal, Instituto de Seguridad Social del Estado de México y Municipios, Toluca, Mexico; 3National Taiwan University Hospital, Taipei, Taiwan; 4Hospital de Caridade de Ijuí, CACON, Ijuí, Brazil; 5Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; 6Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; 7Instituto Brasileiro de Controle do Câncer, São Paulo, Brazil; 8Hospital Pêrola Byington, São Paulo, Brazil; 9Breast Unit, Champalimaud Clinical Center, Champalimaud Foundation, Lisbon, Portugal; 10Novartis Healthcare Pvt. Ltd., Hyderabad, India; 11Novartis Pharmaceuticals Corporation, East Hanover, NJ; 12Novartis Pharma AG, Basel, Switzerland and 13UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA.

Background: Younger patients (pts) with breast cancer may experience more aggressive disease and are more likely to die from their cancer vs older pts. In the Phase III MONALEESA-7 study (NCT02278120), the addition of ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) to a non-steroidal aromatase inhibitor (NSAI) or tamoxifen (TAM) + goserelin significantly prolonged progression-free survival (PFS) in premenopausal women with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC; hazard ratio 0.553; p<0.0001). RIB treatment benefit was observed irrespective of endocrine partner (NSAI or TAM). Here we report results from a MONALEESA-7 subgroup analysis in pts aged <40 yrs and ≥40 yrs who received RIB or placebo (PBO) in combination with an NSAI + goserelin.

Methods: Pre- or perimenopausal women with HR+, HER2– ABC who had received no prior endocrine therapy and ≤1 line of chemotherapy for ABC were enrolled. Of the 672 pts randomized, 495 (74%) received RIB (600 mg/day, 3-weeks-on/1-week-off) or PBO + an NSAI (letrozole [2.5 mg/day] or anastrozole [1 mg/day]) and goserelin (3.6 mg every 28 days). The primary endpoint was locally assessed PFS; secondary endpoints included overall response rate (ORR), clinical benefit rate (CBR), and safety. A prespecified subgroup analysis was performed in pts aged <40 yrs and ≥40 yrs.

Results: A total of 144 pts were aged <40 yrs (RIB vs PBO arm: 78 vs 66) and 351 were aged ≥40 yrs (170 vs 181). As of August 20, 2017, in the RIB vs PBO arms, treatment was ongoing in 50% vs 23% of pts aged <40 yrs and 54% vs 43% of pts aged ≥40 yrs; disease progression was the most common reason for treatment discontinuation (<40 yrs: 37% vs 68%; ≥40 yrs: 35% vs 44%). Median PFS was prolonged in the RIB vs PBO arms both in pts aged <40 yrs (not reached vs 10.8 months; hazard ratio 0.435; 95% confidence interval [CI] 0.276–0.686) and in pts aged ≥40 yrs (27.5 vs 19.1 months; hazard ratio 0.625; 95% CI 0.449–0.870). In pts with measurable disease, the ORR (RIB vs PBO arm) was 49% vs 32% in pts aged <40 yrs and 51% vs 38% in pts aged ≥40 yrs; CBR was 81% vs 61% and 82% vs 65%, respectively. The most common Grade 3 adverse events (AEs; ≥5% of pts in either arm; RIB vs PBO arm) were neutropenia (<40 yrs: 47% vs 5%; ≥40 yrs: 58% vs 3%), leukopenia (<40 yrs: 18% vs 2%; ≥40 yrs: 14% vs 1%), diarrhea (<40 yrs: 5% vs 0; ≥40 yrs: 1% vs 0), and increased alanine aminotransferase (<40 yrs: 4% vs 2%; ≥40 yrs: 5% vs 1%); neutropenia was the only Grade 4 AE occurring in ≥5% of pts in either arm (<40 yrs: 15% vs 0; ≥40 yrs: 8% vs 1%). New post-baseline QTcF >480 ms (RIB vs PBO arm) occurred in 3% vs 2% of pts aged <40 yrs and 7% vs 1% of pts aged ≥40 yrs.

Conclusions: Consistent treatment benefit was observed with RIB + NSAI vs PBO + NSAI in premenopausal women with HR+, HER2– ABC irrespective of age. RIB + NSAI had a manageable safety profile in pts aged <40 yrs and in those aged ≥40 yrs, with a safety profile similar to that observed in the full study population.
First-line ribociclib + endocrine therapy in hormone receptor-positive, HER2-negative advanced breast cancer: A pooled efficacy analysis

Debu Tripathy¹, Gabriel Hortobagyi¹, Arlene Chan², Seock-Ah Im³, Stephen Chia⁴, Denise Yardley⁵, Francisco J Esteva⁶, Sara Hurvitz⁷, Oliver Kong⁸, Weibin Bao⁸, Karen Rodriguez Lorenc⁸, Ivan Diaz-Padilla⁹ and Dennis J Slamon¹⁰. ¹The University of Texas MD Anderson Cancer Center, Houston; ²Breast Cancer Research Centre WA & Curtin University, Perth, Australia; ³Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea; ⁴BC Cancer Agency, Vancouver, Canada; ⁵Sarah Cannon Research Institute and Tennessee Oncology PLLC, Nashville; ⁶NYU Langone Health, New York; ⁷UCLA Jonsson Comprehensive Cancer Center, Los Angeles; ⁸Novartis Pharmaceuticals Corporation, East Hanover; ⁹Novartis Pharma AG, Basel, Switzerland and ¹⁰UCLA Medical Center, Santa Monica.

Background: In three separate Phase III randomized, placebo-controlled trials, ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) + various endocrine therapy (ET) partners prolonged progression-free survival (PFS) vs placebo (PBO) + ET in patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC). Here we further evaluate the efficacy of RIB-based regimens of interest (i.e. with a non-steroidal aromatase inhibitor [NSAI] or fulvestrant [FUL]) in pts who were ET-naïve in the ABC setting, using pooled data from three Phase III trials: MONALEESA (ML)-2 (NCT01958021; all pts), ML-3 (NCT02422615; no prior ET for ABC subgroup only), and ML-7 (NCT02278120; RIB + NSAI subgroup only).

Methods: Postmenopausal pts with no prior ET for ABC received RIB (600 mg/day; 3-weeks-on/1-week-off) or PBO + either letrozole (2.5 mg/day) in ML-2 or FUL (500 mg every 28 days, with an additional dose on Day 15 of Cycle 1) in ML-3. In ML-7, premenopausal pts with no prior ET and ≤1 line of chemotherapy for ABC received RIB or PBO + goserelin (3.6 mg every 28 days) + NSAI (anastrozole [1 mg/day]/letrozole [2.5 mg/day]). The primary endpoint of all three trials was locally assessed PFS. Secondary endpoints included overall response rate (ORR), clinical benefit rate (CBR), and duration of response (DoR; ML-3 and -7). DoR was an exploratory endpoint in ML-2.

Results: Data were pooled for 820 pts treated with RIB + ET (ML-2: n=334; ML-3: n=238; ML-7: n=248) and 710 pts treated with PBO + ET (ML-2: n=334; ML-3: n=129; ML-7: n=247). As of the data cutoffs (ML-2: January 2, 2017; ML-3: November 3, 2017; ML-7: August 20, 2017), in the RIB + ET vs PBO + ET arms, 385 (47%) vs 234 (33%) pts remained on-treatment; the most common reason for discontinuation was disease progression (n=292 [36%] vs n=391 [55%]). In this pooled analysis, median PFS was prolonged for RIB + ET vs PBO + ET, with a hazard ratio of 0.570 (95% confidence interval [CI] 0.491–0.662); median PFS was 25.3 months (95% CI 23.9–29.6) vs 15.6 months (95% CI 14.4–16.9), respectively. Consistent PFS benefit for RIB + ET vs PBO + ET was observed across pt subgroups, including ECOG performance status, age, race, or presence/absence of liver and/or lung metastases or bone-only disease. Among all pts in the pooled analysis, the ORR was 41% for RIB + ET vs 28% for PBO + ET and the CBR was 79% vs 70%, respectively. In pts with measurable disease at baseline (RIB + ET: n=639; PBO + ET: n=542), the ORR was 51% for RIB + ET vs 37% for PBO + ET and the CBR was 79% vs 68%, respectively. In the RIB + ET vs PBO + ET arms, the median DoR was 26.7 months vs 20.0 months. A decrease in best percentage change from baseline in the sum of longest diameters per RECIST was observed in 86% of pts receiving RIB + ET vs 73% of pts receiving PBO + ET.

Conclusions: RIB in combination with various ET partners demonstrates improved clinical outcomes vs PBO + ET across a broad population of pts with HR+, HER2– ABC. These data provide further support for the use of RIB-based combinations in pre- and postmenopausal pts with HR+, HER2– ABC who have received no prior ET for advanced disease.
Ribociclib treatment benefit in patients with advanced breast cancer with ≥1 dose reduction: Data from the MONALEESA-2, -3, and -7 trials

J Thaddeus Beck, Patrick Neven, Joohyuk Sohn, Arlene Chan, Gabe S Sonke, Thomas Bachelot, Saul Campos-Gomez, Miguel Martin, Aditya Bardia, Jahangir Alam, Michelle Miller, Ivan Diaz-Padilla, Oliver Kong and Lowell Hart.

Highlands Oncology Group, Fayetteville, AR; Multidisciplinary Breast Centre, Universitair Ziekenhuis Leuven, Leuven, Belgium; Severance Hospital, Yonsei University Health System, Seoul, Korea; Breast Cancer Research Centre, Nedlands, Western Australia, Australia; Netherlands Cancer Institute/BOOG Study Center, Amsterdam, Netherlands; Centre Léon Bérard, Lyon, France; Centro Oncológico Estatal, Instituto de Seguridad Social del Estado de México y Municipios, Toluca, Mexico; Instituto de Investigación Sanitaria Gregorio Marañon, Ciberonc, Geicam, Universidad Complutense de Madrid, Madrid, Spain; Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA; Novartis Pharmaceuticals Corporation, East Hanover, NJ; Novartis Pharma AG, Basel, Switzerland and Florida Cancer Specialists, Sarah Cannon Research Institute, Fort Myers, FL.

Background: In the MONALEESA (ML) trials, addition of ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) to endocrine therapy (ET) prolonged progression-free survival (PFS) in patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC). RIB was generally well tolerated, with adverse events (AEs) managed effectively by dose modifications. Here we present efficacy data for RIB-based regimens of interest for the proposed indication (i.e. with a non-steroidal aromatase inhibitor [NSAI] or fulvestrant [FUL]) from ML-2, -3, and -7 in pts who received no prior ET for ABC and who had ≥1 RIB dose reduction, to explore the efficacy of RIB in pts who need to dose reduce.

Methods: Pts included in this analysis were: postmenopausal women with HR+, HER2– ABC and no prior ET for ABC who received RIB (600 mg; 3-weeks-on/1-week-off) with letrozole (2.5 mg/day; ML-2 [NCT01958021]), or FUL (500 mg per label; ML-3 [NCT02422615]); and premenopausal women with no prior ET and ≤1 line of chemotherapy for ABC who received RIB with an NSAI (anastrozole: 1 mg/day; letrozole: 2.5 mg/day; ML-7 [NCT02278120]) plus goserelin (3.6 mg every 28 days). Dose reductions for RIB (600 to 400 to 200 mg) were permitted. Primary endpoint was PFS. Secondary endpoints included overall response rate (ORR), clinical benefit rate (CBR), and safety.

Results: In ML-2, -3, and -7, ≥1 RIB dose reduction occurred (n/N) in 169/334 (51%), 92/238 (39%), and 91/246 (37%) pts assigned to RIB, respectively. AEs were the main reason for dose reduction, with all-grade neutropenia the most common AE leading to dose reduction (ML-2 69%, ML-3 80%, ML-7 82%). Median PFS (months) was prolonged with RIB vs placebo in pts without a RIB dose reduction (ML-2: 27.7 vs 16.0; ML-3: not reached [NR] vs 18.3; ML-7: 23.8 vs 13.8); median PFS in pts with ≥1 RIB dose reduction was: ML-2 25.3, ML-3 NR, and ML-7 27.5 months. In pts with measurable disease and without a RIB dose reduction, ORR was 46% (ML-2), 43% (ML-3), and 48% (ML-7); CBR was 70%, 68%, and 79%, respectively. In pts with measurable disease and ≥1 RIB dose reduction, ORR was 62% (ML-2), 57% (ML-3), and 55% (ML-7); CBR was 88%, 85%, and 88%, respectively. The most common Grade 3/4 AEs in the RIB vs placebo groups (≥5% of pts in either ML trial, irrespective of causality or dose reduction) were neutropenia (ML-2: 62% vs 1%; ML-3: 55% vs 0%; ML-7: 65% vs 4%), leukopenia (ML-2: 21% vs 1%; ML-3: 12% vs 0%; ML-7: 16% vs 1%), hypertension (ML-2: 13% vs 13%; ML-3: 5% vs 5%; ML-7: 2% vs 3%), increased alanine aminotransferase (ML-2: 10% vs 1%; ML-3: 10% vs 0%; ML-7: 5% vs 1%), and increased aspartate aminotransferase (ML-2: 6% vs 1%; ML-3: 6% vs 0%; ML-7: 4% vs 1%).

Conclusions: Results from the ML-2, -3, and -7 trials suggest that pts who start on 600 mg of RIB and require dose reduction for the management of their AEs, or for other reasons, continue to derive clinical benefit.
Ribociclib + endocrine therapy in patients with hormone receptor-positive, HER2-negative advanced breast cancer presenting with visceral metastases: Subgroup analysis of phase III MONALEESA trials

Sarah Cannon Research Institute and Tennessee Oncology PLLC, Nashville, TN; Breast Cancer Research Centre, Nedlands, Western Australia, Australia; Practice for Haematology and Internal Oncology, Velbert, Germany; Netherlands Cancer Institute and BOOG Study Center, Amsterdam, Netherlands; National Cancer Centre Singapore, Singapore, Singapore; Centre Léon Bérard, Lyon, France; NYU Langone Health, New York, NY; UCLA Medical Center, Santa Monica, CA; Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN; Novartis Healthcare Pvt. Ltd., Hyderabad, India; Novartis Pharmaceuticals Corporation, East Hanover, NJ; Novartis Pharma AG, Basel, Switzerland and University of Ottawa, Ottawa, ON, Canada.

Background: Patients (pts) with advanced breast cancer (ABC) who present with visceral metastases (mets) have a poorer prognosis vs pts with non-visceral disease. In the Phase III MONALEESA (ML) trials, ribociclib (RIB) + endocrine therapy (ET) prolonged progression-free survival (PFS) vs placebo (PBO) + ET in hormone receptor-positive (HR+), HER2-negative (HER2–) ABC. Here we show data for pts with and without visceral mets from the ML-2, -3, and -7 trials.

Methods: Data were collated from 3 trials in HR+, HER2– ABC: in ML-2 (NCT01958021; data cutoff [DCO] Jan 2/4, 2017), postmenopausal pts (no prior ET for ABC) received RIB or PBO + letrozole; in ML-3 (NCT02422615; DCO Nov 3, 2017), postmenopausal pts (no prior ET for ABC subgroup only) received RIB or PBO + fulvestrant; in ML-7 (NCT02278120; DCO Aug 20, 2017), premenopausal pts (no prior ET and ≤1 chemotherapy for ABC) received RIB or PBO + goserelin + anastrozole/letrozole. Endpoints: primary: local PFS; secondary: overall response rate (ORR), clinical benefit rate (CBR), safety.

Results: Of all 820 pts treated with RIB + ET, 484 (59%) had visceral mets (ML-2 197/334; ML-3 137/238; ML-7 150/248); of all 710 pts treated with PBO + ET, 416 (59%) had visceral mets (ML-2 196/334; ML-3 77/129; ML-7 143/247). Median PFS was prolonged for RIB vs PBO in pts with and without visceral mets (Table). ORR and CBR were also higher for RIB vs PBO in pts with and without visceral mets. The most common (≥10% of pts in any arm) Grade 3 and 4 adverse events (AEs) for each trial are shown in the table; no G4 AEs occurred in ≥10% of pts in ML-3.

**Conclusions:** Although the presence of visceral mets is associated with a poorer prognosis, RIB + ET is an effective and well-tolerated treatment option for pts with HR+, HER2– ABC irrespective of the presence of visceral mets.
Everolimus + exemestane for HR+ advanced breast cancer in routine clinical practice- Final results from the non-interventional trial, BRAWO

Diana Lüftner¹, Florian Schuetz², Andreas Schneeweiss², Eva-Maria Grischke³, Wilhelm Bloch⁴, Thomas Decker⁵, Christoph Uleer⁶, Christoph Salat⁷, Frank Förster⁸, Marcus Schmidt⁹, Christoph Mundhenke¹⁰, Hans Tesch¹¹, Christian Jackisch¹², Thomas Fischer¹³, Gernot Guderian¹⁴, Sven Hanson¹⁵ and Peter Fasching¹⁶. ¹Charité University Medicine, Campus Benjamin Franklin, Berlin, Germany; ²University Hospital Heidelberg, Heidelberg, Germany; ³Universitätäts-Frauenklinik Tübingen, Eberhard Karls University, Tübingen, Germany; ⁴German Sport University Cologne, Cologne, Germany; ⁵Studienzentrum Onkologie Ravensburg, Ravensburg, Germany; ⁶Gyn.-onkologische Gemeinschaftspraxis Hildesheim, Hildesheim, Germany; ⁷Hematology-Oncology Clinic, Munich, Germany; ⁸Poliklinik GmbH Chemnitz, Chemnitz, Germany; ⁹Johannes Gutenberg University, Mainz, Germany; ¹⁰University of Kiel, Kiel, Germany; ¹¹Oncological Practice Bethanien, Frankfurt, Germany; ¹²Sana Klinikum Offenbach GmbH, Offenbach, Germany; ¹³Winicker Norimed GmbH, Nuernberg, Germany; ¹⁴Novartis Pharma GmbH, Nuernberg, Germany; ¹⁵Novartis Pharma GmbH, Goettingen, Germany and ¹⁶University Hospital Erlangen, Comprehensive Cancer Center Erlangen-EMN, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany.

Background: In the pivotal BOLERO-2 trial, everolimus (EVE) + exemestane (EXE) more than doubled the median progression-free survival (PFS) vs EXE alone in hormone receptor positive (HR+), human epidermal growth factor-receptor 2-negative (HER2-) advanced breast cancer (ABC) recurring/progressing on/after prior non-steroidal aromatase inhibitors (NSAIs). BRAWO is a German non-interventional study conducted in patients (pts) with HR+, HER2–ABC receiving EVE + EXE, according to Summary of Product Characteristics (SmPC), in routine clinical practice. Here we report the final PFS and safety results.

Methods: This multicenter study documented 2100 pts between October 2012 and December 2017 across 341 sites in Germany. Postmenopausal women with HR+, HER2– ABC with recurrence or progression after a NSAI were included. Primary observation parameters included the evaluation of the effectiveness of EVE + EXE used in routine care for the entire pt group.

Results: In the final analysis, out of the 2100 documented pts, 2074 were included in the full analysis set. The median time since the primary diagnosis was 7.1 years and the median time from first sign of relapse (local recurrence or distant metastases) was 2.1 years. At baseline, 54.1% of pts presented with visceral metastases and 50.1% had an ECOG performance status of 0. Approximately, 63% of pts started with EVE 10 mg (median duration of exposure: 5.1 months; 95% CI, 4.6-5.4), while 34.1% started with EVE 5 mg (median duration of exposure: 4.6 months; 95% CI, 4.1-5.2). The distribution of treatment lines was as follows: first line, 28.7% (n=595); second line, 31.9% (n=662); third line, 18.1% (n=376); fourth line, 10.7% (n=221) and, fifth line and later, 10.6% (n=220). Treatment was discontinued by 55.7% of pts (n=1170) due to progressive disease and 26% of pts (n=546) due to adverse events. The Kaplan-Meier estimate of the median PFS was 6.6 months (95% CI, 6.2-7.0). The best overall responses, based on clinical routine, were complete response, 0.8% (n=17), partial response, 7.4% (n=150), and stable disease, 41.3% (n=842). The general safety profile was consistent with the previously reported safety findings. The most common adverse events were stomatitis (any grade: 42.6%, grade 3: 3.8%, grade 4: <0.1%) and fatigue (any grade: 19.8%, grade 3: 1.5%).

Conclusions: Data from BRAWO support EVE + EXE as a suitable treatment option with a reasonable safety profile for HR+, HER2– ABC recurring or progressing on/after prior NSAIs.
Clinical management of metastatic breast cancer (MBC) after CDK 4/6 inhibitors: A retrospective single-institution study

Karthik V Giridhar1, Grace M Choong1, Roberto A Leon-Ferre1, Ciara C O’Sullivan1, Kathryn J Ruddy1, Tufia C Haddad1, Timothy J Hobday1, Prema P Peethambaram1, Timothy J Moynihan1, Charles L Loprinzi1, Minetta C Liu1, Vera J Suman1 and Matthew P Goetz1. 1Mayo Clinic, Rochester, MN.

Cyclin dependent kinase 4 and 6 inhibitors (CDK4/6i) are standard first line (1L) and second line (2L) treatments of ER+ MBC. However, the optimal treatment strategy after progression on a CDK 4/6i is unknown. Given concern for rapid disease progression after discontinuation of CDK4/6is (Bashour, J Cancer 2017), further data on responses to subsequent lines of therapy post CDK4/6i are needed. We performed a single institution retrospective review of patients (pts) with ER+ MBC who received 1L or 2L CDK4/6i to examine the prescribing patterns and clinical responses to post-CDK4/6i treatment.

Methods: We identified 136 ER+ MBC pts prescribed a CDK4/6i at Mayo Clinic Rochester (from 12/2014 to 2/2018) on 1L or 2L who received at least 30 days of therapy and ≥ two clinic visits during treatment. For the 1L and 2L cohorts we assessed the time to treatment failure during (TTF-1) and after CDK4/6i therapy (TTF-2). TTF was defined as time from start of therapy to discontinuation for any cause. Additionally, we assessed overall survival (OS) post CDK4/6i discontinuation (defined as the date of TTF-1 to death or last follow up).

Results: The study cohort included 81 and 55 pts treated with 1L and 2L CDK4/6is, respectively. In the 1L cohort, palbociclib/letrozole (82.3%) and palbociclib/fulvestrant (13.6%) were most commonly prescribed. Treatment was discontinued in 39/81 pts due to: progression (84.6%), intolerability (7.7%), and other (7.7%). The median TTF-1 was 19.7 mo (95% CI 11.2 – 25.4 mo). Subsequent treatment and response data were available in 37/39 pts that progressed on 1L CDK4/6i. The most commonly prescribed regimens included single-agent hormonal therapy (29.7%), everolimus/exemestane (27.0%), and single agent chemotherapy (21.7%). The overall median TTF-2 were as follows: everolimus/exemestane 13.2 mo [95%CI 0.33 mo – not reached (NR)]; single agent hormonal therapy 3.1 mo (95%CI 1.4 – 5.4 mo); and single agent chemotherapy 4.1 mo (95%CI 1.4 – 5.4 mo). With a median post-CDK4/6i follow up of 11.2 mo, we observed 8 deaths and the median OS-post CDK4/6i was NR.

In the 2L cohort, common regimens were palbociclib/letrozole (63.6%) and palbociclib/fulvestrant (27.3%). Treatment was discontinued in 30/55 pts due to: progression (73.3%), intolerability (13.3%), and other (13.3%). The median TTF-1 in the 2L cohort was 8.3 mo (95%CI 4.6 – 12.7 mo). Subsequent treatment data were available in 24/30 pts and included single-agent hormonal therapy [n=7 (29.2%); median TTF-2 4.7 mo; 95%CI 1.9 – 14.0 mo], everolimus/exemestane [n=6 (25.0%); median TTF-2 3.2 mo, 95% CI 0.8-10.1 mo] and single agent chemotherapy [n=6 (25.0%); median TTF-2 2.6 mo; 95%CI 1.7 mo – NR].

With a median post-CDK4/6i follow up of 18.7 mo in the 2L cohort, we observed 11 deaths, and the median OS-post CDK4/6i was 11.8 mo (95%CI 11.8 mo – NR).

Conclusions: Single and combination-based endocrine strategies are commonly administered post-CDK4/6i without clinical evidence for rapid deterioration. The observation of a median treatment duration lasting >12 months in patients receiving everolimus/exemestane post-CDK4/6i supports ongoing studies evaluating drugs that target PI3K/mTOR pathway in combination and following progression on a CDK4/6i.
A phase 1b/2 study of ribociclib plus trastuzumab for the treatment of advanced, treatment-refractory HER2-positive breast cancer

Shom Goel¹, Laura Spring², Rebecca Rees¹, Chelsea Andrews¹, Rie K Tahara¹, Erica L Mayer¹, Aditya Bardia², Eric P Winer¹ and Sara M Tolaney¹. ¹Dana-Farber Cancer Institute, Boston, MA and ²Massachusetts General Hospital, Boston, MA.

Introduction:
Despite the success of anti-HER2 therapy, acquired resistance usually develops in the metastatic setting. CDK4/6 pathway activity has been identified as a mediator of this resistance, and in preclinical studies the combination of CDK4/6 and HER2 blockade can be more effective than either therapy alone. We conducted a single-arm phase 1b/2 study of the CDK4/6 inhibitor ribociclib given with trastuzumab or T-DM1 to subjects with advanced, treatment-refractory HER2-positive breast cancer. The results of the trastuzumab cohort are presented below. The primary objective was to determine the clinical benefit rate (CBR) at 24 weeks, and secondary endpoints included objective response rate (ORR), progression-free survival (PFS), and adverse events.

Methods: Individuals with locally advanced or metastatic, measurable HER2-positive breast cancer were eligible. All subjects must have previously received trastuzumab, pertuzumab, and T-DM1 as (neo)adjuvant or metastatic therapy. There was no limit on the number of prior lines of treatment. Patients with previous CDK4/6 inhibitor exposure, QTcF > 450msec on EKG, or without stable brain metastases were excluded. An initial safety run-in phase (with dose-limiting toxicity (DLT) monitoring) included six subjects who received trastuzumab (8mg/kg loading then 6mg/kg IV three-weekly) and ribociclib 400mg PO daily on a continuous schedule (cycle length 21 days). The study had a two-stage design. The first stage required 20 patients, at least 6 of whom must have demonstrated clinical benefit (CR+PR+ SD>24 weeks) in order to recruit 15 more patients to the second stage. All patients with accessible disease underwent metastatic tumor biopsies at baseline and C2D1.

Results: 13 patients were enrolled (6 in the safety run-in and 7 in the expansion cohort). One patient was found to have HER2-negative disease and did not receive treatment. Patient characteristics are shown in Table 1

Table 1

<table>

<td>2.5 (2 - 5)</td>
</tr>
</tbody>
</table>

No DLTs were observed during the safety run-in phase, and ribociclib was thus used at 400mg po daily for the expansion cohort. Grade 3/4 toxicities were observed in 5 patients (41.7%) and included neutropenia (n=2), and fatigue, pain, and muscle weakness (all n=1). No patient demonstrated QTc prolongation >480 msec, or grade 3/4 LFTs. 1/12 patients ((8.3%); 95% CI 0.2%-38.5%) achieved stable disease>24 weeks; no objective responses were observed, and median PFS was 41.5 days. The trastuzumab portion of study was closed early due to limited clinical activity observed (the T-DM1 with ribociclib cohort remains open).

Conclusions: The combination of trastuzumab and ribociclib (400mg daily continuous schedule) is safe, with no new safety signals observed. The limited activity seen in this heavily pretreated population suggests that future efforts to incorporate CDK4/6 inhibition should be limited to a less extensively treat population.
Long-term responders to single-agent margetuximab, an Fc-modified anti-HER2 monoclonal antibody, in metastatic HER2+ breast cancer patients with prior anti-HER2 therapy

Seock-Ah Im1, Yung-Jue Bang1, Do-Youn Oh1, Giuseppe Giaccone2, Todd Bauer3, Jeff Nordstrom4, Hua Li4, Paul Moore4, Shengyan Hong4, Jan Baughman4, Edwin Rock4 and Howard Burris3. 1Seoul National University Hospital, Seoul, Republic of Korea; 2Georgetown University, Washington, DC; 3Sarah Cannon Research Institute, Nashville, TN and 4MacroGenics, Inc., Rockville, MD.

Background
Margetuximab is an Fc-optimized anti-HER2 antibody that recognizes the same epitope as trastuzumab. Margetuximab has increased affinity for the activating CD16A Fc-receptor on NK cells and macrophages as well as decreased affinity for the inhibitory CD32B receptor compared to trastuzumab. In a Phase 1 study (NCT01148849) of 66 patients with relapsed or metastatic HER2+ cancer across multiple indications, margetuximab was well tolerated at all doses. Among 60 response-evaluable patients, confirmed partial response (PR) and stable disease (SD) were seen in 7 (12%) and 30 (50%) patients, respectively. Tumor reductions occurred in 18/23 (78%) evaluable breast cancer patients. Ex-vivo analyses of patient peripheral blood mononuclear cell samples confirmed margetuximab’s ability to enhance antibody dependent cell-mediated cytotoxicity over that from trastuzumab. We report on 3 breast cancer patients with prior anti-HER2 therapy failure with durable (≥3.5 years) SD (1) or PR (2).

Methods
Enrolled patients had histologically/cytologically-confirmed carcinoma with documented HER2 overexpression by immunohistochemistry (2+ or 3+) and disease progression during/following last therapy. Eligibility included life expectancy ≥3 months; performance status ≤1; measurable disease by Response Criteria for Solid Tumors 1.1; adequate bone marrow, renal, hepatic function; and left ventricular ejection fraction ≥50%. Margetuximab was given by intravenous infusion at 0.1 – 6.0 mg/kg for 3 of every 4 weeks or once every 3 weeks (10 – 18 mg/kg).

Results
Three of 17 HER2 3+ metastatic breast cancer patients received long-term margetuximab. Patient 35 had 3 prior regimens (adjuvant doxorubicin+cyclophosphamide followed by docetaxol+trastuzumab; gemcitabine+vinorelbine; lapatinib+capecitabine) and received margetuximab at 10 mg/kg q3wk, 88 cycles to date, with PR achieved Cycle 1 Day 43, maintained 4.4 years. Patient 44 had 3 prior regimens for metastatic disease (docetaxel+trastuzumab+pertuzumab; doxorubicin+cyclophosphamide; lapatinib+capecitabine) and received margetuximab at 15 mg/kg q3wk, 79 cycles to date with SD for 4.3 years. Patient 50 had 4 prior regimens for recurrent/metastatic disease (tamoxifen; anastrozole; capecitabine+trastuzumab; lapatinib+capecitabine) and received margetuximab dose of 18 mg/kg q3wk with PR achieved Cycle 1 Day 43, maintained 3.5 years. Progression was noted at Cycle 57, and margetuximab continues at 63 cycles to date. No cardiac toxicities were found during long-term follow-up for these 3 patients and there were no treatment-related adverse events ≥Grade 3.

Conclusions
Margetuximab is well-tolerated without cardiac toxicities in long-term responders, with single-agent activity including durable responses in heavily pre-treated metastatic breast cancer. A Phase 3, randomized, multi-center clinical trial (SOPHIA; NCT02492711) is enrolling patients with metastatic breast cancer, comparing margetuximab plus chemotherapy to trastuzumab plus chemotherapy in patients who have received 1 to 3 lines of therapy for advanced disease.
EMBRACA: Efficacy and safety of talazoparib or physician’s choice of therapy in patients with advanced breast cancer and a germline BRCA1/2 mutation: A regional analysis

Lida Mina¹, Kyung-Hun Lee², Anthony Gonçalves³, Natasha Woodward⁴, Sara A Hurvitz⁵, Sami Diab⁶, Rinat Yerushalmi⁷, Annabel Goodwin⁸, Marina Moreira Costa Zorzetto⁹, Sung-Bae Kim¹⁰, Akos Czibere¹¹, Iulia Cristina Tudor¹¹, Eric Gauthier¹¹, Jennifer K Litton¹² and Johannes Ettl¹³. ¹Banner Health, Phoenix, AZ; ²Seoul National University Hospital, Seoul, Republic of Korea; ³Aix-Marseille Université, Inserm, CNRS, Institut Paoli-Calmettes, CRCM, Marseille, France; ⁴Mater Cancer Care Centre – Mater Health Services/Mater Research Institute, South Brisbane, Australia; ⁵University of California, Los Angeles, Los Angeles, CA; ⁶University of Colorado Cancer Center, Aurora, CO; ⁷Rabin Medical Center, Beilinson Hospital, Petah Tikva, Israel; ⁸Concord Repatriation General Hospital, Sydney, Australia; ⁹Barretos Cancer Hospital, São Paulo, Brazil; ¹⁰Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; ¹¹Pfizer, Inc., Cambridge, MA; ¹²The University of Texas MD Anderson Cancer Center, Houston, TX and ¹³Klinikum rechts der Isar, Technische Universität München, Munich, Germany.

Background: Talazoparib (TAL) prevents DNA damage repair by inhibiting poly (ADP-ribose) polymerase (PARP) enzymes and trapping PARP on DNA, resulting in cell death in BRCA1/2-mutated cells.

Methods: EMBRACA is an open-label, randomized, 2-arm phase 3 trial in which efficacy and safety of TAL (1 mg/d) were compared with physician’s choice of therapy (PCT; capecitabine, eribulin, gemcitabine, vinorelbine) in patients (pts) with locally advanced or metastatic breast cancer (ABC) and a germline BRCA mutation (gBRCAm). Outcomes were assessed by region of the world (North America [NA]; Europe [EU]; rest of world [ROW]). Progression-free survival (PFS), objective response rate (ORR), and clinical benefit rate (CBR) at 24 wks were assessed; safety was also assessed.

Results: 431 pts were randomized 2:1. Pt characteristics were well balanced, although a higher percentage of pts in ROW had more severe disease (eg, triple-negative breast cancer [TNBC], Disease-free interval [DFI]<12 mo, more distant metastases, more disease sites) and were on average younger than pts in NA/EU. TAL provided improvement in PFS, ORR, and CBR in all regions vs PCT. The most common toxicities with TAL included anemia, neutropenia, thrombocytopenia, fatigue, and nausea for all regions. Alopecia was less frequent with TAL in EU/ROW. Serious adverse events for pts receiving TAL were more frequent in EU than NA/ROW. Incidences of adverse events associated with permanent treatment discontinuation in pts receiving TAL were low in all regions and generally lower than for PCT.

Identification of optimal combination therapy partners for PI3K/Akt/mTOR pathway inhibitor in triple negative breast cancer

Maryam Shariati¹, Natalia Paez-Arango¹, Christopher A Bristow¹, Kurt W Evans¹, Michael D Peoples¹, Alessandro Carugo¹, Tim P Heffernan¹ and Funda Meric-Bernstam¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX.

Triple-negative breast cancer (TNBC) is among the most aggressive subtypes, accounts for 10-15% of all breast cancer cases and is characterized by a lack of hormone receptors with a low overall survival rate. Due to the heterogeneity nature of this disease, the absence of validated molecular targets makes it unresponsive to conventional therapies. PI3K/Akt/mTOR pathway is aberrantly activated in TNBC, but single agent therapy is commonly subject to resistance. The goal of this study is to identify the genes that can be targeted to enhance the efficacy of mTOR inhibitor TAK228, an agent that is being investigated as a treatment for advanced solid tumors, in TNBC with PI3K pathway activation. We utilized an in vivo pooled barcoded shRNA library screening to determine the genes that have the potential to be used as TAK228 synthetic lethal partners. Using deep sequencing analysis of the shRNA profiles, we identified several genes whose loss of function conferred synthetic lethality in the presence of TAK228. We found that targeting the candidate genes (WEE1, BMX and MAPK15) with their inhibitors (AZD1775, Ibrutinib and Sunitinib) did not significantly affect the viability, however combination treatment of these agents with TAK228 induced a robust growth inhibition and demonstrated a significant synergy in MDA-MB-468 cell lines. Investigating the activation of relevant survival signaling pathways will further elucidate the mechanism of synthetic lethal interaction. These observations provide a promising rational strategy for the treatment of TNBC with PI3K pathway aberration.
Patient-reported outcomes with ribociclib-based therapy in hormone receptor-positive, HER2-negative advanced breast cancer: results from the phase III MONALEESA-2, -3, and -7 trials

J Thaddeus Beck, Patrick Neven, Francisco J Esteva, Aditya Bardia, Nadia Harbeck, Sara Hurvitz, Joyce O'Shaughnessy, Sunil Verma, Brad Lanoue, Jahangir Alam, Oliver Kong, David Chandiwana and Stephen Chia.

Highlands Oncology Group, Fayetteville; Multidisciplinary Breast Centre, Universitair Ziekenhuis Leuven, Leuven, Belgium; NYU Langone Health, New York; Massachusetts General Hospital, Harvard Medical School, Boston; Breast Center, University of Munich (LMU), Munich, Germany; UCLA Jonsson Comprehensive Cancer Center, Los Angeles; Texas Oncology-Baylor Charles A. Sammons Cancer Center and US Oncology Network, Dallas; Tom Baker Cancer Centre, Calgary, Canada; Novartis Pharmaceuticals Corporation, East Hanover and BC Cancer Agency, Vancouver, Canada.

Background: In the Phase III MONALEESA (ML) trials, ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) + endocrine therapy (ET) significantly improved progression-free survival (PFS) vs placebo (PBO) + ET in patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC). Here we report key patient-reported outcomes (PROs) for pts treated with RIB-based regimens of interest (i.e. with a non-steroidal aromatase inhibitor [NSAI] or fulvestrant [FUL]) in the ML-2, -3, and -7 trials.

Methods: Postmenopausal pts with HR+, HER2– ABC and no prior ET for advanced disease received RIB (600 mg/day; 3-weeks-on/1-week-off) + letrozole (2.5 mg/day; ML-2 [NCT01958021]), or FUL (500 mg every 28 days, with an additional dose on Day 15 of Cycle [C] 1; ML-3 [no prior ET for ABC subgroup only; NCT02422615]). Premenopausal pts with no prior ET and ≤1 line of chemotherapy for advanced disease received RIB + NSAI (anastrozole [1 mg/day]/letrozole [2.5 mg/day]) + goserelin (3.6 mg every 28 days; ML-7 [NCT02278120]). The primary endpoint for all trials was PFS. PROs were a secondary endpoint of all trials and were evaluated using EORTC QLQ-C30, QLQ-BR23 (ML-2 and ML-7), EQ-5D-5L, WPAI-GH (ML-7 only), and BPI-SF (ML-3 only) questionnaires. Changes from baseline and time to 10% deterioration (TTD) in health-related quality of life (HRQoL) were analyzed using linear mixed-effect and stratified Cox regression models, respectively.

Results: A total of 1530 pts were included in this analysis. Questionnaire compliance was high across trials (ML-2/ML-3: >90%; ML-7: >80%). On-treatment HRQoL (EORTC QLQ-C30 global health status.quality of life [QoL] score) was maintained from baseline up to C34, C28, and C17 in both treatment arms for ML-2, ML-3, and ML-7, respectively. In ML-7, mean overall HRQoL scores continued to improve in the RIB arm from C18 to C28, but scores decreased in the PBO arm. At end of treatment, mean overall HRQoL scores decreased in both arms across trials. Median TTD (RIB vs PBO) was similar between arms, favoring the RIB arms (ML-2: 27.7 vs 27.6 months; hazard ratio 0.944; 95% confidence interval [CI] 0.720–1.237; ML-3: not reached [NR] vs 22.4 months; hazard ratio 0.721; 95% CI 0.484–1.074; ML-7: 24.0 vs 19.4 months; hazard ratio 0.759; 95% CI 0.561–1.028). Clinically meaningful reductions in EORTC QLQ-C30 pain score (<5 points from baseline) were observed in the RIB arm of ML-2 from as early as C3 and were sustained vs only at C7 and C13 in the PBO arm. Clinically meaningful reductions in pain were observed from C22 to C28 in the RIB arm of ML-7 vs only at C28 in the PBO arm. In ML-3, clinically meaningful reductions in pain were observed from C3 to C5, C11–17, and at C22 and C28 in the RIB arm vs C17–C25 in the PBO arm. Furthermore, median TTD of the BPI-SF pain severity index score was NR in either arm of ML-3 (hazard ratio 0.858; 95% CI 0.554–1.330).

Conclusions: In addition to significantly prolonging PFS, RIB consistently maintains QoL regardless of ET combination partner. RIB + ET is also associated with clinically meaningful reductions in pain vs PBO + ET across a broad population of pts with HR+, HER2– ABC.
Ribociclib + endocrine therapy in hormone receptor-positive, HER2-negative advanced breast cancer: A pooled safety analysis

Howard A Burris¹, Arlene Chan², Seock-Ah Im³, Stephen Chia⁴, Debu Tripathy⁵, Francisco J Esteva⁶, Mario Campone⁷, Aditya Bardia¹¹, Oliver Kong⁸, Weibin Bao⁸, Ivan Diaz-Padilla⁸, Karen Rodriguez Lorenc⁸ and Denise A Yardley¹⁰. ¹Sarah Cannon Research Institute, Tennessee Oncology, Nashville; ²Breast Cancer Research Centre – WA, Nedlands, Australia; ³Seoul National University Hospital, Cancer Research Institute, and Seoul National University College of Medicine, Seoul, Korea; ⁴BC Cancer Agency, Vancouver, Canada; ⁵The University of Texas MD Anderson Cancer Center, Houston; ⁶NYU Langone Health, New York; ⁷Centre René Gauducheau, Institut de Cancérologie de l'Ouest, Saint-Herblain, France; ⁸Novartis Pharmaceuticals Corporation, East Hanover; ⁹Novartis Pharma AG, Basel, Switzerland; ¹⁰Sarah Cannon Research Institute and Tennessee Oncology PLLC, Nashville and ¹¹Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston.

**Background:** In Phase III trials, ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) + various endocrine therapy (ET) partners has demonstrated significantly prolonged progression-free survival vs placebo (PBO) + ET in patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC). Here we further evaluate the safety of RIB-based regimens of interest for the proposed indication (i.e. with a non-steroidal aromatase inhibitor [NSAI] or fulvestrant [FUL]) using pooled data from three Phase III trials (MONALEESA [ML]-2 [NCT01958021], -3 [NCT02422615], and -7 [NCT02278120]).

**Methods:** Postmenopausal pts with HR+, HER2– ABC received RIB (600 mg/day; 3-weeks-on/1-week-off) or PBO + letrozole (LET; 2.5 mg/day; ML-2 [no prior ET for ABC]) or FUL (500 mg, Days 1 and 15 of Cycle 1, then Day 1 of every cycle thereafter; ML-3; no or ≤1 prior line of ET for ABC)). Premenopausal pts (ML-7; no prior ET and ≤1 chemotherapy for ABC)) received RIB or PBO + anastrozole (1 mg/day)/LET (2.5 mg/day) + goserelin (3.6 mg every 28 days). Adverse events (AEs) were characterized per Common Terminology Criteria for Adverse Events v4.03; safety analyses included time to first event, duration of event, and rate of associated RIB/PBO discontinuations.

**Results:** Data for 1883 pts were pooled; 1065 pts received RIB + ET and 818 pts received PBO + ET (median exposure to study treatment: 17 and 13 months, respectively). Exposure-adjusted incidence rates for AEs of special interest were 561 and 131 per 100 pt-years in the RIB and PBO arms, respectively. The most common all-causality Grade 3/4 AEs (≥10% in any arm; RIB vs PBO) were neutropenia (59% vs 2%), leukopenia (18% vs 1%), and hypertension (13% vs 13%). A new Fridericia's corrected QT interval (QTcF) >480 ms occurred in (n/N) 52/1054 (5%) vs 11/814 (1%) pts in the RIB vs PBO arms; a new QTcF >500 ms occurred in 14/1054 (1%) vs 1/814 (<1%) pts. Median time to first event for Grade ≥2 neutropenia, elevated alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST), and QTc prolongation in the RIB arm was 2, 12, and 2 weeks, respectively; median duration of first Grade ≥2 event was 4, 4, and 2 weeks. In the RIB arm vs PBO arms, 7% vs 3% of pts discontinued study treatment due to AEs; common all-grade AEs leading to RIB/PBO discontinuation (≥2% in any arm) were elevated ALT (4% vs <1%) and elevated AST (2% vs 1%). Discontinuation due to QT prolongation occurred in 4 pts in the RIB arm and 2 in the PBO arm (both <1%). All-grade serious AEs occurred in 25% of pts in the RIB arm vs 15% of pts in the PBO arm.

**Conclusions:** RIB in combination with various ET partners continues to demonstrate a predictable and manageable tolerability profile across a broad population of pts with HR+, HER2– ABC.
Ribociclib (RIBO) + letrozole (LET) in older patients with hormone receptor-positive (HR+), human epidermal growth factor receptor-2–negative (HER2–) advanced breast cancer (ABC): Preliminary subgroup results from the phase 3b CompLEEment-1 trial

Alistair Ring1, Simona Borstnar2, Ana Ferreira3, Hamdy A Azim4, Paul Cottu5, Janice Lu6, Miguel Martin7, Claudio Zamagni8, J Thaddeus Beck9, Katie Zhou10, Jiwen Wu10, Lakshmi Menon10 and Michelino De Laurentiis11. 1Royal Marsden NHS Foundation Trust, Surrey, United Kingdom; 2Institute of Oncology Ljubljana, Ljubljana, Slovenia; 3Instituto Português de Oncologia do Porto, Porto, Portugal; 4Cairo University, Cairo, Egypt; 5Institut Curie, Paris, France; 6University of Southern California, Los Angeles, CA; 7Instituto de Investigación Sanitaria Gregorio Marañón, Ciberonc, Geicam, Universidad Complutense, Madrid, Spain; 8Addarii Medical Oncology Unit, S. Orsola-Malpighi Hospital, Bologna, Italy; 9Highlands Oncology Group, Fayetteville, AR; 10Novartis Pharmaceuticals, East Hanover, NJ and 11National Cancer Institute “Fondazione Pascale”, Napoli, Italy.

**Background:** The cyclin-dependent kinase (CDK)4/6 inhibitor RIBO is approved in combination with an aromatase inhibitor (AI) for HR+, HER2– ABC in postmenopausal women with no prior therapy for ABC, based on the MONALEESA-2 trial (Hortobagyi et al. NEJM 2016). Although a high proportion of patients with HR+, HER2– ABC are >65 years of age, older patients are often under-represented in clinical trials. Furthermore, treatment decisions may be complicated by comorbidities, functional status, and concurrent medications. Here, we report early safety results for patients ≥65 years of age enrolled in CompLEEment-1, an open-label, phase 3b trial evaluating RIBO+LET as first-line endocrine-based therapy in an expanded patient population.

**Methods:** Patients with HR+, HER2– ABC, ≤1 line of prior chemotherapy (CT), and no prior endocrine therapy for ABC received RIBO (600 mg/day, 3 weeks on/1 week off) + LET (2.5 mg/day); men and premenopausal women received concomitant goserelin (3.6-mg subcutaneous implant every 28 days). The primary outcome was safety and tolerability. A pre-planned interim analysis was conducted ~15 months after first patient first visit.

**Results:** Of the first 1,008 patients enrolled who completed 56 days of follow-up or discontinued before the data cut-off date, 377 were ≥65 years of age. Of these, 157 (41.6%) were 65-<70 years, 107 (28.4%) were 70-<75 years, and 113 (30%) were ≥75 years. The majority of patients (94.4%) had an Eastern Cooperative Oncology Group performance status ≤1; 33.2% presented with stage IV disease at diagnosis; 9 patients were male. The most common sites of metastasis were bone (70.0%), lung (44.8%), and lymph nodes (29.7%). The most common all-grade adverse events (AEs) were neutropenia (58.4%), nausea (31.8%), and fatigue (24.1%). The most common grade 3/4 AEs were neutropenia (37.7%) and alanine aminotransferase increase (4.2%). QT prolongation events were mild (majority grade 1/2) and occurred in 6.1% of patients (0.5% grade 3/4). Dose reduction or interruption due to AEs occurred in 54.5% of patients; 6.9% of patients had AEs leading to treatment discontinuation. In the overall patient population, the most frequent grade 3/4 AEs were neutropenia (42.8%), leukopenia (3.4%), and increased alanine aminotransferase (2.9%); QT prolongation occurred in 5.4% of patients (0.5% grade 3/4).

**Conclusions:** Initial safety results from CompLEEment-1, from the first 56 days of follow-up, demonstrate the tolerability of RIBO+LET in older patients, consistent with the overall patient population. NCT02941926.
Ribociclib + letrozole in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–) advanced breast cancer (aBC) with no prior endocrine therapy (ET) for aBC: CompLEEment-1 trial, preliminary results from Spanish population

Javier Salvador1, Eva Mª Ciruelos2, Aleix Prat3, Begoña Jiménez-Rodríguez4, Luis de la Cruz5, Noelia Martínez6, Rafael Villanueva Vázquez7, Rubén de Toro8, Antonio Antón9, Fernando Moreno10, Isabel Alvarez11, Joaquín Gavila12, Vanesa Quiroga13, Elena Vicente14, Juan de la Haba15, Santiago González-Santiago16, Nieves Díaz17, Agustí Barnadas18, Blanca Cantos Sánchez de Ibargüen19, Juan Ignacio Delgado20, Meritxell Belle21, Asunción Gimeno22, Silvia Sanz23 and Miguel Martín23. 1Virgen del Rocío University Hospital. **Background:** The phase III Monaleesa-2, Monaleesa-3 and Monaleesa-7 trials have shown significantly improved PFS for the combination ribociclib + ET vs ET + placebo in pre-, peri-, and postmenopausal women with HR+/HER2–, first and second line aBC. The Compleement-1 trial is a phase IIIb, single-arm, open-label, international study to assess the safety and efficacy of ribociclib + letrozole in men and women who have not received prior ET for HR+, HER2– aBC [J Clin Oncol 36, 2018 (suppl; abstr 1056)].

**Methods:** 526 patients with HR+, HER2– aBC, ≤1 line of prior CT, and no prior ET for aBC were enrolled in the Compleement-1 trial in Spain from April 2017 to January 2018. Patients received ribociclib (600 mg/day, 3 weeks on/1 week off) + letrozole (2.5 mg/day); men and premenopausal women received concomitant goserelin (3.6 mg subcutaneous implant every 28 days). The primary objective was safety and tolerability. Here we report on a sub-analysis from the Spanish population of Compleement-1 trial including baseline characteristics and early safety results for the first patients enrolled who completed at least 56 days of follow-up or discontinued before the cut-off date (3rd Oct 2017).

**Results:** One hundred fifty four patients constituted the analytical cohort for this sub-analysis. Demographics and baseline characteristics: median age was 52 years (range 24-82); 1% of patients were male, 31.8% female pre-menopausal and 67.5% female post-menopausal; 44.2% vs 38.3% of patients had visceral disease vs bone only disease; 49.9% patients had ≥2 metastatic sites; and 34.4% of patients presented as de novo stage IV. The median exposure for study treatment was 1.8 months (range 0.8-1.8). The grade 3/4 events reported >1% included neutropenia (50%), increased GGT levels (3.2%), leukopenia (1.3%), and increased ALT (1.3%). QTcF prolongation >480ms based on ECG data was reported in 1.2% patients. Median dose intensity for ribociclib was 600mg/day (range 476.5-600); 11% of patients required one dose reduction (8.4% due to AEs), 59.7% had at least one dose interruption (57.1% due to AEs) and 9.7% were permanently discontinued (4.5% due to AEs).

**Conclusions:** Preliminary safety results from this Compleement-1 sub-analysis including Spanish population are consistent with previous data presented from Monaleesa-2, Monaleesa-3, Monaleesa-7 and Compleement-1. These data support the predictable and manageable safety profile of ribociclib in combination with letrozole. Clinical trial information: NCT02941926
Phase I trial of eribulin and everolimus in patients with metastatic triple negative breast cancer

Yuan Yuan1, Susan Yost1, Suzette Blanchard1, Holly Yin1, Min Li1, Kim Robinson1, Aileen Tang1, Norma Martinez1, Lucille Leong1, George Somlo1, Niki Tank Patel1, James Waisman1, Jana Portnow1, Arti Hurria1, The-hang Luu2 and Joanne Mortimer1. 1City of Hope National Medical Center, Duarte, CA and 2OncoGambit, Irvine, CA.

Background: Alteration of PI3K/Akt/mTOR pathway is the most common genomic abnormality detected in triple negative breast cancer (TNBC). Everolimus acts synergistically with eribulin in inducing apoptosis in TNBC cell lines and xenografts in our preclinical study. This phase I trial was designed to test the safety and tolerability of combining eribulin and everolimus in patients (pts) with metastatic TNBC.

Methods: The overall objective of this study was to describe the safety and toxicities of the combination. The secondary objective was to assess activity based on response rate (RR) and progression free survival (PFS). Eligibility criteria included pts with metastatic TNBC, ECOG 0-2, 0-3 lines of prior chemotherapy in metastatic setting, and prior treatment with anthracycline and/or taxane therapy. The study utilized the toxicity equivalence range (TEQR) design with a target equivalence range for dose-limiting toxicities (DLTs) of 0.20-0.35. The recommended phase 2 dose (RP2D) will be the dose closest to the target of 0.25 below 0.51 based on isotonic regression. Three dosing levels of the combinations were tested: level A1 (everolimus 5mg daily; eribulin 1.4 mg/m2 days 1, 8 every 3 weeks), level A2 (everolimus 7.5mg daily; eribulin 1.4 mg/m2, days 1, 8 every 3 weeks), level B1 (everolimus 5mg daily; eribulin 1.1 mg/m2 days 1, 8 every 3 weeks). Nanostring RNA analysis and genomic mutation analysis were conducted in 16 pts with available tumor tissue.

Results: A total of 27 pts were enrolled. Median age was 55 years (range 36-76). Two pts were ineligible due to HER2+ on repeat biopsy and were only included in the toxicity analysis. Dose level B1 (everolimus 5mg daily and eribulin 1.1 mg/m2 days 1, 8 every 3 weeks) was determined to be the RP2D doses. The DLTs were neutropenia, stomatitis and hyperglycemia. Across all cycles, 59% (16/27) had a ≥ Gr3 toxicity attributed to treatment at the possible or above level. 44% (12/27) had Gr3 heme-toxicities. The most common toxicities were ≥ Gr3 neutropenia (10 pts), Gr3 lymphopenia (6 pts) and ≥ Gr3 leukopenia (7 pts). 33% (9/27) had Gr3 non-heme toxicities. The most common were Gr3 stomatitis (3 pts), Gr3 hyperglycemia (3 pts) and Gr3 fatigue (5 pts). The median number of cycles completed was 4 (0-8). 68% (17/25) had a dose modification or hold, 14 of 25 (56%) were for eribulin and 15 of 25 (60%) were for everolimus. Of 25 eligible pts, 8 (32%) achieved a best response as partial response, 11 (44%) had stable disease and 6 (24%) had progression. 80% (20/25) experienced progression by RECIST or showed clinical progression, and the median time to progression was 2.7 mo (95% CI (2.2, 4.6)). At the time of this analysis, 16 participants had died, median OS was 6.3 mo (95% CI (5.3, undefined)). Two pts are still being followed on treatment. PI3K-Akt-mTOR pathway genes and mutations profiles were studied.

Conclusion: Eribulin 1.1 mg/m2 days 1, 8 and everolimus 5mg daily was defined as the RP2D. Genomic analysis is currently underway to understand the molecular mechanisms of resistance.
Real-world survival of heavily pretreated patients with refractory HR+, HER2- metastatic breast cancer receiving single-agent chemotherapy - A Comparison with MONARCH 1

Hope Rugo¹, Veronique Dieras², Javier Cortes³,⁴, Debra Patt⁵,⁶, Hans Wildiers⁷, Joyce O'Shaughnessy⁷, Esther Zamora⁴, Denise Y Yardley¹⁰, Gebr Ayun Carter³, Kristin M Sheffield², Li Li², Valerie AM Andre⁵, Rosemary E Derbyshire³, Xiaohong I Li³, Martin Frenzel¹⁰, Yu-Jing Huang⁴,  Maura N Dickler⁹ and Sara M Tolaney¹¹.¹ University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; ²Centre Eugene Marquis UNICANCER, Rennes Cedex, France; ³Ramon y Cajal University Hospital, Madrid, Spain; ⁴Vall d’Hebron Institute of Oncology, Barcelona, Spain; ⁵Texas Oncology, Austin, TX; ⁶US Oncology, Dallas, TX; ⁷University Hospital Gasthuisberg, Leuven, Belgium; ⁸Baylor University Medical Center, Texas Oncology, US Oncology, Dallas, TX; ⁹Eli Lilly and Company, Indianapolis; ¹⁰Sarah Cannon Research Institute, Tennessee Oncology PLLC, Nashville, TN and ¹¹Dana-Farber Cancer Institute, Boston.

Background
In MONARCH 1 (NCT02102490), abemaciclib demonstrated promising single-agent activity and tolerability in a population of heavily pretreated women with refractory HR+, HER2- metastatic breast cancer (MBC).¹ Confirmed objective response rate (ORR) was 19.7% (95% CI: 13.3, 27.5) and at 18 months minimum follow-up median overall survival (OS) was 22.3 months. Due to the single-arm trial design of MONARCH 1, there is a need to view these results in clinical context relative to available treatment options. This study compared the OS results of abemaciclib in MONARCH 1 vs that in a real-world single-agent chemotherapy cohort with similar patient and disease characteristics.

Methods
MONARCH 1 study design and key eligibility criteria were previously described.¹ The real-world cohort was based on Flatiron Health electronic health records-derived, nationally representative (USA-based) database comprising patient-level structured and unstructured data, curated via technology-enabled abstraction, for patients with MBC between January 1, 2011 through February 28, 2018. A real-world single-agent chemotherapy cohort was created based on the key eligibility criteria of MONARCH 1 and included patients diagnosed with HR+, HER2- MBC who received single-agent chemotherapy (eribulin, capecitabine, gemcitabine, or vinorelbine) following 1-2 prior chemotherapy regimens in the metastatic setting, had an ECOG PS of 0-1, and no prior CDK4 & 6 therapy. The index date was the start of the eligible single-agent chemotherapy, and patients were followed from the index date until date of death, loss to follow-up, or end of the database, whichever occurred earlier. OS results were adjusted using 2 methods (Mahalanobis distance matching and entropy balancing with bootstrapping) to account for baseline demographic and clinical differences between the real-world and trial cohorts.

Results
A real-world cohort (n=281) with eligibility criteria similar to the MONARCH 1 population (n=132) was identified. A subsequent matching based on Mahalanobis distance was performed to match MONARCH 1 population (n=108) with the real-world cohort (n=108). The matched cohorts demonstrated similar patient and disease characteristics. Median OS was 22.3 months in the abemaciclib arm vs 13.6 months in the matched cohort with an estimated hazard ratio (HR) of 0.54 (95% CI: 0.37, 0.77). Results of a sensitivity analysis performed using entropy balancing were consistent with an adjusted median OS of 12.7 months in the real-world cohort (n=281)with HR of 0.57 (95% CI from bootstrapping: 0.44, 0.78).

Conclusion
Methodological advances to adjust for potential biases, and improvements in data quality, have evolved enabling the ability to leverage a real-world cohort as an external comparator arm. This study demonstrates the ability to create a real-world chemotherapy cohort suitable to serve as a comparator for MONARCH 1. These exploratory results suggest a survival advantage and adequately place the clinical benefit of abemaciclib monotherapy in clinical context.

Targeting mitochondrial function for the treatment of triple negative breast cancer: Development of a small molecule inhibitor against mitochondrial STAT3

Madhu M Kanchi¹, Jayshree L Hirpara¹, Karishma Sachaphibulkij², Tuan Zee Tan¹, Henrik Dietzel³, Lina HK Lim⁴, Ruby Yun-Ju Huang¹,⁵, Shazib Pervaiz²,⁴, Jiri Neuzil⁶ and Alan Prem Kumar¹,²,⁷. ¹Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore; ²Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; ³Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark; ⁴NUS Graduate School for Integrative Sciences and Engineering, National University of Singapore, Singapore, Singapore; ⁵National University Health System, Singapore, Singapore, Singapore; ⁶School of Medical Science, Gold Coast Campus, Griffith University, Brisbane, Australia and ⁷Cancer Program, Medical Science Cluster, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore.

Background: Patients with Triple Negative Breast Cancer (TNBC) can benefit significantly from earlier diagnosis/prognosis, targeted therapy, and predictive biomarker panels for optimal therapy. However, currently there are no clinically accepted markers for the prognosis of TNBC and to predict its potential to metastasize. It is well documented that numerous cancer subtypes with increased mitochondrial oxidative phosphorylation in which enhanced mitochondrial activity is linked to aggressiveness. Also, there is greater awareness of metabolic heterogeneity within tumors, with some cells using glycolysis as their main energy source, whereas others use oxidative phosphorylation. Interestingly, TNBC has been shown to adopt increased mitochondrial biogenesis to “fuel” enhanced growth and aggressiveness. Signal Transducers and Activators of Transcription family 3 (STAT3) has been studied extensively as a transcription factor, however the finding that STAT3 also localizes to mitochondria has opened a new area to discover non-classical functions.

Methods: Targeting mitochondrial STAT3 functions challenge the current design of therapies that solely target STAT3 as a transcription factor and suggest the need for “design thinking,” to intervene the STAT3 pathway. With this in mind, we developed an in-house mitochondrial targeting - MitoTam. Data from in vitro cell-based assays, in vivo subcutaneous xenograft and patient-derived xenograft (PDX) models of TNBC will be reported.

Results: Our data shows MitoTam robustly inhibited proliferation of TNBC cells at pharmacological doses and induced apoptosis. Mechanistically, we observed the MitoTam was able to target STAT3 leading to the downregulation of genes which is highly upregulated in most of the cancers. Furthermore, we show inhibition of STAT3 transcriptional activity hampers mitochondrial biogenesis, a prominent feature of cancer cell. Interestingly our in vivo and in vitro protein data showed the decreased phosphorylation of nuclear STAT3 and decreased mitochondria import of STAT3. We also found the decreased phosphorylation of STAT3 is associated with the interaction of GRIM-19 which is a cell death regulatory protein in complex1. Treatment of MitoTam was able to deplete the super complexes involved in OXPHOS and also in the regulation of mitochondrial transcription regulation. Our in vivo and PDX models show significant reduction of tumor size and tumor burden with treatment of MitoTam without effecting body mass. In addition we also found decrease in protein kinases associated with regulation of STAT3 for tumor survival. In addition, nuclear DNA encoded mitochondrial transcription factor A (TFAM), which enhances both transcription and replication of mitochondrial DNA is also shown to be downregulated with treatment, suggesting that MitoTam effectively inhibit TFAM binding to the mitochondrial DNA genes involved in OXPHOS regulation which was further validated by TFAM Chip-seq.

Conclusion: Our results places MitoTam is a promising candidate drug against TNBC and establish mitochondrial STAT3 as its molecular target.
Real world treatment patterns and outcomes of patients receiving palbociclib plus fulvestrant in the United States: Sub-groups analysis based on age, performance status and sites of metastases

John Waller¹, Debanjali Mitra², Gavin Taylor-Stokes¹, Katie Gibson¹, Gary Milligan¹, Lin Zhan² and Shrividya Iyer². ¹Adelphi Real World, Bollington, United Kingdom and ²Pfizer, New York, NY.

**Background:** Ibrance Real World Insights (IRIS) is a multi-country study aimed to describe the clinical characteristics and understand treatment patterns and clinical outcomes of patients receiving palbociclib plus fulvestrant in real world clinical practice. Previously the results on the overall population within the US have been communicated. The current analyses focus on subgroups stratified by age, performance status and visceral status.

**Materials and methods:** A retrospective chart review of HR+/HER2- ABC/MBC patients was conducted between June and October 2017. Physicians extracted data from patient medical records for HR+/HER2- ABC patients who received palbociclib plus fulvestrant following disease progression with endocrine based therapy for their advanced disease. Electronic case report forms collected data covering patient demographics, clinical characteristics, treatment history/patterns and clinical outcomes. Progression free rates and survival rates at 6 and 12 months were estimated via Kaplan-Meier analysis.

**Results:** Data for the US are reported here. In total, 65 physicians extracted data for 292 patients who had a mean follow up time of 7.4 months. Majority of the patients were >65 years (54%), and had ECOG status of 0 (32%) or 1 (48%). Overall 224 (77%) patients had metastatic disease, of which 93 (42%) had visceral metastases. Across all sub-groups, majority of patients prescribed an initial palbociclib dose of 125mg did not require a change of dose while on treatment. The 6-month and 12-month progression free and survival rates across subgroups are presented in Table 1. Patients with a performance status of ECOG ≥ 2 had a slightly lower progression and survival rates at 6 and 12 months compared to those with a score <1. Likewise, patients with visceral disease were observed to have slightly lower progression free and survival rates than others.

**Conclusions:** The analysis indicates consistent trends in different clinical outcomes were observed with palbociclib plus fulvestrant across patients sub-groups based on age, performance status and visceral metastases.
Phase Ib study of rebastinib plus antitubulin therapy with paclitaxel (P) or eribulin (E) in patients with HER2-negative metastatic breast cancer (MBC)

Jesus D Anampa¹, Xiaonan Xue², Sun-young Oh¹, Noah Kornblum¹, Sara Sadan³, Maja H Oktay², John Condeelis² and Joseph A Sparano¹. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY and ³White Plains Hospital, White plains, NY.

BACKGROUND: TMEM (Tumor Microenvironment of Metastasis) are the portal for tumor cell intravasation into the circulation and subsequent metastasis (Harney et al Cancer Discov 2015). The potent Tie2 kinase inhibitor rebastinib inhibits intravasation at TMEM sites, reduces circulating tumor cell (CTC) burden, increases angiopoietin (Ang) 1/2 levels, prevents distant metastases, and improves survival in breast cancer animal models when added to either P or E (Harney et al MCT 2017), and circumvent chemotherapy-induced pro-metastatic changes in the tumor microenvironment mediated by TMEM (Karagiannis et al STM 2017). We sought to determine the safety of rebastinib combined with antitubulin therapy (P or E) in patients with HER2- MBC. We also hypothesized that addition of rebastinib would reduce CTC burden and increase Ang levels by blocking Ang-mediated stimulation of VEGF release from TMEM-associated macrophages.

METHODS: We aimed to determine the safety and recommended phase 2 dose (RP2D) of rebastinib (2 dose levels: 50 mg or 100 mg PO BID) in combination with P (80 mg/m² x 12 weeks) or E (1.4 mg/m² on day 1 & 8 q 21 days) using a standard 3+3 design (1 cycle = 21 days). Secondary objectives included evaluating the effect of the P/E + rebastinib combination on CTCs (TelomeScan) and Ang levels. Dose limiting toxicity (DLT) was defined as grade 3-4 febrile neutropenia, thrombocytopenia, and non-hematologic toxicity during the first 6 weeks of therapy. Eligibility included HER2- MBC, ECOG PS 0-1, CDK4/6 inhibitor progression if ER+. Patients with ≤2 prior non-taxane chemotherapy regimens received P+ rebastinib, whereas those with ≥2 chemo regimens (including a taxane) received E+ rebastinib.

RESULTS: Of 11 treated patients, 6 received rebastinib + P and 5 received rebastinib + E (2 non-evaluable due to rapid disease progression and non-compliance). Among 11 patients who received 60 treatment cycles, only 1 patient (treated with eribulin) had grade 3 events (anemia and neuropathy after week 6) potentially related to treatment. When combined with P, the RP2D of rebastinib was 100 mg PO BID, with DLT occurring in 0/6 patients. When combined with E, 0/3 evaluable patients had a DLT at 50 mg BID of rebastinib (accrual ongoing for 100mg BID). Best response included partial response/stable disease in 4(2PR/2SD) of 6 treated with P+ rebastinib, and 1(1PR) of 5 treated with E+ rebastinib. CTCs decreased during therapy (median decrease 99.7 %) and 4/8 patients converted from CTC+ to CTC-. Ang1 levels increased during therapy in 8 patients (0.2-7.0 fold), while Ang2 levels were also increased in 8 patients (0.2-1.4 fold).

CONCLUSIONS: When combined with P x 12 weeks, the RP2D of rebastinib is 100 mg PO BID. When combined with E, the RP2D of rebastinib is at least 50mg PO BID; however, the 100 mg PO BID dose level is still accruing patients. The P/E + rebastinib combinations are associated with antitumor activity and exhibit pharmacodynamic evidence indicating blockade of Tie2 (increased Ang) and TMEM function (reduced CTCs) We plan to further evaluate the P+ rebastinib combination as neoadjuvant therapy in the I-SPY program, and continue further evaluation of P/E + rebastinib combinations in MBC.
Palbociclib and endocrine therapy in fourth line and beyond for hormone receptor-positive HER2-negative advanced breast cancer: The UK compassionate access program experience

Background
Palbociclib is approved in 1st line for hormone receptor (HR)-positive HER2-negative advanced breast cancer (ABC). A Compassionate Access Program (CAP) previously allowed patients to receive it in 4th line. However, Palbociclib has not been specifically tested in this population. We aimed to determine the safety and efficacy profile of Palbociclib within the CAP across ten institutions in the United Kingdom.

Methods
We retrospectively identified HR-positive HER2-negative ABC patients on the Palbociclib CAP between December 2015 and September 2017. Demographics, disease characteristics, prior treatments, blood tests, toxicities, treatment delays and responses were recorded. Simple statistics, Fisher's exact test, chi-squared method and Cox regression were used as appropriate.

Results
118 patients identified had median age of 59 (32-82). 97 (82.20%) were postmenopausal and 109 (92.37%) had ECOG Performance Status 0-1. 96 (81.36%) had visceral involvement, 19 (16.10%) bony only and 15 (12.71%) visceral only disease. Patients received a median 5 (range 3-11) prior lines of treatment and 3 (range 0-8) prior chemotherapy lines. 105 patients (89.74%) developed neutropenia (grade ≥3 in 59 [56.19%]). 6 experienced febrile neutropenia (5.13%). 57 (48.72%) had a dose reduction, down to 100mg in 48 (41.03%) and 75mg in 9 (7.69%) due to hematologic toxicity in 46 (80.70%). Dose delays were in median 7 days long (range: 0-56). Palbociclib was discontinued due to disease progression in 97 (82.91%) and to toxicity in 5 (4.27%). Grade 3 neutropenia occurred in 45 patients (67.16%) who received ≥3 and in 22 (32.84%) who received <3 prior chemotherapies (p 0.351).

Palbociclib produced clinical benefit rate (CBR) of 47.52% and overall response rate of 15.84% in 101 patients assessed. CBR was 45.45% with previous endocrine treatment (ET) progression-free survival (PFS) ≥6 months versus 49.12% if PFS <6 months (p 0.714).

Overall, median PFS was 4.5 months (95% CI 3.7-5.9). The PFS seen in different subgroups showed no impact in relation to the number of lines of prior chemotherapy (<3 lines: 5.9 months [95% CI 3.7-11.0]; ≥3 lines: 4.3 months [95% CI 3.3-5.5], p 0.159), but was numerically greater in those who had previous benefit from ET (PFS ≥6 months: 5.9 months [95% CI 4.4-8.0]; <6 months: 3.7 months [95% CI 2.8-4.5], p 0.055) or in those with bone only disease (bone only: 11.0 months [95% CI 2.3-not reached]; other sites involved: 4.4 months [95% CI 3.6-5.5], p 0.024).

Median OS was 15.8 months (95% CI 13.3-18.7) for the whole cohort and it was greater in patients who derived longer PFS from prior ET (≥6 months: 18.1 months [95% CI 13.0-NR]; <6 months: 14.4 months [95% CI 7.7-18.3], p 0.052).

Conclusions
To date, this is the most extensive analysis of Palbociclib outcomes in ≥4th-line setting. In this heavily pretreated population clinical benefit was confirmed particularly for endocrine-sensitive disease and predominantly involving the bones and in earlier lines of treatment. Grade ≥3 neutropenia rates were similar to PALOMA trials, but the higher incidence of febrile neutropenia need to be carefully considered.
Lapatinib-based therapies after pertuzumab and/or T-DM1 for HER2+ metastatic breast cancer patients

Simona Frezzini¹, Tommaso Giarratano², Maria Vittoria Dieci¹,², Carlo Alberto Giorgi³, Gaia Griguolo¹, Grazia Vernaci¹, Alice Menichetti¹, Mara Mantiero¹, Giulia Tasca¹, Giovanni Faggioni², Cristina Falci², Federica Miglietta¹, Eleonora Mioranza², Silvia Angelini¹, Cristina Ghiotto², PierFranco Conte¹,² and Valentina Guarneri¹,². ¹Università di Padova, Padova, Italy and ²Istituto Oncologico Veneto - IRCCS, Padova, Italy.

Background:
Trastuzumab + pertuzumab + taxane and ado-trastuzumab emtansine (T-DM1) are standard first and second-line therapies for HER2+ metastatic breast cancer. Lapatinib is approved in combination with capecitabine in trastuzumab-resistant patients and in combination with letrozole in hormone receptor positive HER2+ pts for whom endocrine treatment is indicated. In Italy, L is also approved in combination with trastuzumab for hormone receptor-negative HER2+ pts. There are only few data on the activity of lapatinib in pts who received prior pertuzumab and/or T-DM1.

Methods: We retrospectively analysed HER2+ metastatic breast cancer pts who received lapatinib after prior pertuzumab and/or T-DM1 from July 2013 to June 2018. Objective response rate (ORR) was assessed according to RECIST 1.1. Progression-free survival (PFS) was calculated from lapatinib-based therapy starting to disease progression (PD) or last follow-up. Overall Survival (OS) was calculated from lapatinib-based therapy starting to death or last follow up.

Results: Data from 32 HER2+ mBC treated with lapatinib-based therapy were recorded: 30 pts (94%) received lapatinib combined with capecitabine, 1 pt received lapatinib combined with letrozole and 1 pt received lapatinib combined with trastuzumab. All patients had been treated with prior T-DM1 and 9 (28%) with prior pertuzumab for metastatic breast cancer. Setting of treatment with lapatinib-based therapy was: 2° line (n=2, 6%), 3° line (n=17, 53%) and ≥4° line (n=13, 41%). Patients characteristics were as follows: median age 55 years (range 35-71), hormone receptor positive 66% (n=21), stage IV at diagnosis 34% (n=11), visceral involvement at lapatinib-based therapy starting 91% (n=29). As of June 2018, lapatinib-based therapy was ongoing for 4 pts and 28 pts discontinued treatment due to disease progression (median number of courses for these pts was 8.5, range 2-27).

ORR in evaluable pts was: complete response (n=1, 3%), partial response (n=13, 41%), stable disease (n=9, 28%), disease progression (n=9, 28%). Median PFS was 6.4 months (95% CI 3.0-9.8). As of June 2018, 14 pts (44%) were alive, median OS was 11.8 months (95% CI 9.9-13.6).

Conclusion: These results confirm that lapatinib-based therapy retains clinical efficacy in HER2+ metastatic breast cancer pts treated with prior pertuzumab and/or T-DM1 and represents a valid therapeutic option in this setting.
First-line treatment with ribociclib and letrozole in advanced breast cancer: First interim data from US patients enrolled in the phase 3b CompLEEment-1 clinical trial

Janice Lu¹, Mikhail I Shtivelband², Zahi Mitri³, Linnea Chap⁴, Das Purkayastha⁵, Amrita G Sawhney⁵ and J Thaddeus Beck⁶.
¹University of Southern California, Los Angeles, CA; ²Ironwood Cancer & Research Center, Chandler, AZ; ³Oregon Health & Science University, Portland, OR; ⁴Beverly Hills Cancer Center, Beverly Hills, CA; ⁵Novartis Pharmaceuticals Corporation, East Hanover, NJ and ⁶Highlands Oncology Group, Fayetteville, AR.

**Background:** Addition of ribociclib to aromatase inhibitors significantly increased median progression-free survival in postmenopausal women in the MONALEESA-2 trial and premenopausal women in the MONALEESA-7 trial with hormone receptor–positive (HR+), human epidermal growth factor 2–negative (HER2−) advanced breast cancer (ABC). The global phase 3b CompLEEment-1 trial (Clinicaltrials.gov, NCT02941926) was designed to assess this treatment approach in a cohort of patients with HR+/HER2− ABC that was larger and more diverse than that of the MONALEESA program, particularly in the United States where underrepresented/underserved patient groups were targeted. Here we present the first interim safety analysis of the subset of US patients in the CompLEEment-1 trial.

**Methods:** Women (premenopausal and postmenopausal) and men with HR+/HER2− ABC, ≤1 line of prior chemotherapy, Eastern Cooperative Oncology Group performance status ≤2, and no prior endocrine therapy for ABC received open-label treatment with ribociclib (600 mg/d, 3 weeks on/1 week off) and letrozole (2.5 mg/d). Men and premenopausal women were required to use concomitant goserelin (3.6-mg subcutaneous implant every 28 days). Targeted enrollment in the overall study is ~3000 patients. Patients with ≥56 days of follow-up at the data cutoff (October 3, 2017) were included in the first interim analysis (n=1008). The primary endpoint is safety and tolerability.

**Results:** In the first interim analysis, the US cohort of CompLEEment-1 included 128 patients, 94% of whom were continuing to receive treatment in the study. This cohort included 4 male patients (3%) and 18 patients not identified as white (14%); median age was 62.0 years (Table). The most common adverse events (AEs; >30%) were neutropenia (48%), nausea (45%), and fatigue (36%). The most common grade ≥3 AEs were neutropenia (30%) and leukopenia (6%); all other grade ≥3 AEs occurred in <5% of patients. Rates of AEs leading to discontinuation and dose interruption/adjustment were 5% and 52%, respectively. Four patients experienced at least 1 postbaseline QTcF >480 ms by local assessment. Grade ≥3 increases in alanine aminotransferase and aspartate aminotransferase levels occurred in 3 (2%) and 4 (3%) patients, respectively. There was 1 on-treatment death resulting from a serious AE, bradycardia, that was considered by the investigator to be treatment related.

**Conclusions:** The first interim safety data for ribociclib + letrozole from US patients in the CompLEEment-1 study, which included a broader population reflective of real-world clinical practice, are consistent with the global study population and previously reported safety profiles from the MONALEESA trials.

Ado-trastuzumab for the treatment of metastatic HER2-amplified breast cancer patients previously treated with pertuzumab

Luai S Al Rabadi¹, Andy Kaempf¹, Jeong Y Lim¹, Megan M Saraceni¹, Michael A Savin¹ and Zahi I Mitri¹. ¹Oregon Health & Science University, Portland, OR.

BACKGROUND: Ado-trastuzumab (T-DM1) is an antibody-drug conjugate of trastuzumab and a cytotoxic microtubule-inhibitory agent, emtansine. T-DM1 is approved for the treatment of advanced HER2-amplified breast cancer that progressed following trastuzumab-based therapies based on improvement in progression-free survival (PFS) and overall survival (OS) compared to the therapy of physician choice. However, T-DM1 trials were conducted prior to the widespread adoption of docetaxel, trastuzumab, and pertuzumab as standard frontline therapy for advanced HER2-amplified breast cancer. As such, none of the patients enrolled on T-DM1 studies had been exposed to pertuzumab, and the clinical benefit of T-DM1 in patients previously treated with pertuzumab therapy is unknown.

METHODS: We completed a retrospective review of patients at our institution over the age of 18 with metastatic HER2-amplified breast cancer treated with pertuzumab prior to T-DM1 between February 2013 and May 2018. Data was collected on patient and tumor characteristics, number and duration of therapies in the metastatic setting, and clinical outcomes. The primary endpoint of this study was PFS in patients given T-DM1 after earlier exposure to pertuzumab. Secondary endpoints included overall response rate (ORR), prolonged duration of T-DM1 therapy (> 6 months), and OS. Adverse events following T-DM1 were collected using CTCAE 4.03, with a focus on cardiac dysfunction and peripheral neuropathy. Patient features and outcomes were summarized with descriptive statistics and time-to-event measures were analyzed using the Kaplan-Meier method and log-rank test.

RESULTS: Twenty patients met the inclusion criteria and are included in this study. The patient population consisted of 18 non-Hispanic white and 2 black women, with a median age of 58.5 (range 34-68) years. The number of prior systemic therapies (excluding pertuzumab) ranged from 0-8 with a median of 1 therapy. The duration of T-DM1 therapy (started, on average, 24 months after metastatic diagnosis) ranged from < 1 month to 3.5 years with a median of 6 months. T-DM1 therapy was overall very well tolerated, with all adverse events being grade ≤2. Of note, 2 patients had grade 2 neuropathy, and one patient had grade 1 cardiotoxicity, without any change in left ventricular ejection.

Among 18 patients evaluable for response, ORR was 16.7% (95% CI: 3.6% to 41.4%), with 3 patients achieving a partial response. No complete responses were noted. 10/18 (55.6%) patients had prolonged duration of therapy with T-DM1. Median follow-up time after initiation of T-DM1 was 15 months and 6/20 (30%) patients died while under observation. At the time of data cut-off, 10/20 patients had disease progression on T-DM1. Median PFS was 16 months, with a 1-year PFS rate of 54.5% (95% CI: 36.4% to 81.7%). The 1-year OS rate was 75.0% (95% CI: 58.2% to 96.6%). Patients with liver metastases (n=8) had a significantly worse PFS (p=0.003).

CONCLUSION: T-DM1 following pertuzumab is well tolerated and shows excellent efficacy in the treatment of HER2-positive metastatic breast cancer. Comparing T-DM1 following pertuzumab to T-DM1 in pertuzumab-naïve patients should be explored in this patient population.
Patterns of treatment and outcome of palbociclib plus endocrine therapy in hormone receptor-positive (HR+)/HER2 receptor-negative (HER2-) metastatic breast cancer (MBC): A real life multicenter Italian study

Raffaella Palumbo1, Rosalba Torrisi2, Erica Quaquarini1, Federico Sottotetti1, Anna Gambaro3, Elena Collovà4, Antonella Ferzi4, Sergio Fava4, Elisa Agostinetto2, Barbara Tagliaferri1, Luca Licata1, Cristina Teragni1 and Antonio Bernardo1. 1Medical Oncology, IRCCS ICS Maugeri, Pavia, Italy; 2Humanitas Cancer Center, Istituto Clinico Humanitas, Rozzano, Milano, Italy; 4Medical Oncology, ASST Fатегабенфрателли Сакко PO Sacco, Milano, Italy and 4Medical Oncology, ASST Ovest Milanese, Ospedale di Legnano, Legnano, Italy.

Background
The CDK4/6 inhibitor palbociclib combined with endocrine therapy has proven to prolong progression-free survival (PFS) in previously untreated and pretreated women with HR+/HER2- MBC. Few data are available regarding the performance of such a regimen outside the clinical trials, and there is the need to understand its performances in real world.

Methods
We report a multicenter real-life experience aimed to verify the patterns of treatment and outcome of palbociclib plus endocrine therapy in an unselected population of MBC patients (pts). The primary endpoint was clinical benefit rate (CBR: complete response [CR], partial response [PR], or stable disease for longer than 6 months [SD]); secondary aims were median progression-free survival (mPFS) and safety of the combination. Statistical analysis was performed to identify variables potentially predictive of outcomes. Patients received P at 125 mg daily, 3 wk on/1 wk off in a 28d cycle, combined with letrozole administered orally 2.5 mg on a continuous daily dosing schedule (cohort A) or Fulvestrant 500 mg (F500) i.m. q4wks with loading dose (cohort B); treatment was given until disease progression, toxicity or patient’s refusal.

Results
The study enrolled 150 postmenopausal pts (65 in cohort A, 85 in cohort B) treated from December 2016 to April 2018 at 4 Italian Institutions. Median age in the whole population was 62 years (range 47-79; mean age 59 years in cohort A, 64 in cohort B); 13 pts (20%) in cohort A and 23 pts (27%) in cohort B had de novo metastatic disease; 46% of pts in cohort A and 55% had visceral involvement, while 17% and 20% respectively had bone-only disease. The median number of prior lines was 2 in cohort A (range 1-3) and 3 (range 2-5) in cohort B, including ET (median 3) and chemotherapy (median 2); in cohort B 37 pts (43%) had previously received F 500, while 12% (cohort A) and 15% (cohort B) had been pretreated with everolimus. In cohort A a PR as best response was observed in 32% (20 pts), with 14 pts (23%) achieving SD lasting ≥6 months for a CBR of 52%. In cohort B CBR was 60%, with 25% PR, 48% SD lasting ≥6 months in 35 pts (41%).

The most common adverse events in both cohorts were neutropenia (grade 1-2 in 67%, grade 3-4 in 35%), grade 1 anemia (52%) and thrombocytopenia (34%), requiring dose reduction in 27% of cases. At a median follow-up of 12 months (range 1-16), mPFS was 6.3 months in cohort A and 5.5 months in cohort B. In both groups a better mPFS was observed in pts treated as ≤3rd versus >3rd line: 9.6 versus 5.2 in cohort A (p=0.003), 8.8 versus 4.1 months in cohort B, respectively (p= 0.002). No significant outcome differences were observed according to prior endocrine therapy with F500 or everolimus, or dominant metastatic site.

Conclusions
Our real life data, in line with the results of reported clinical trials, indicate that palbociclib plus letrozolo or F500 is active and safe in HR+/HER2- MBC, also suggesting a better performance of the combinations in earlier treatment lines.
Real-world treatment patterns and clinical outcomes with palbociclib combination therapy received in US community oncology practices

Jeffrey Trocio¹, Junji Lin², Maxine D Fisher², Nan Hu², Cralen Davis², Lynn McRoy¹, Mark S Walker² and Shrividya Iyer¹. ¹Pfizer, Inc., New York, NY and ²Vector Oncology, Memphis, TN.

Background:
The treatment landscape for women with HR+/HER2- advanced and metastatic breast cancer (A/MBC) is changing as new agents are being combined with more established treatments to achieve greater efficacy in combating resistant and unresponsive disease. The present study is designed to describe patient characteristics, treatment patterns, and clinical outcomes in a cohort of women with HR+/HER2- A/MBC treated with palbociclib plus aromatase inhibitor (P+AI) or palbociclib plus fulvestrant (P+FV) in the US community oncology setting.

Methods:
Retrospective medical record data from adult women diagnosed with HR+/HER2- A/MBC who initiated P+AI or P+FV for treatment of A/MBC on or after February 3, 2015 were collected from the Vector Oncology Data Warehouse, a network comprised of 10 community oncology practices across the US. Descriptive analyses were performed on patient characteristics, treatment patterns, and clinical outcomes. Time to event outcomes (progression-free rate (PFR) and survival rate (SR)) at 12 (PFR-12, SR-12) and 24 (PFR-24, SR-24) months for the P+AI combination as first line endocrine therapy and 12 and 18 months for the P+FV combination as treatment following prior endocrine based therapy in either the adjuvant or metastatic setting.

Results:
Among 304 patients who received palbociclib combination therapy, 281 (92.4%) received it per labeled indication. Of the 281 on-label users, the focus of reporting here, 233 (82.9%) received P+AI as their initial endocrine therapy after A/MBC diagnosis; 48 (17.1%) received P+FV after prior endocrine therapy for breast cancer. Patient mean age (SD) was 63.1 (11.4) and 68.2 (10.2) years for patients receiving P+AI and P+FV, respectively. Patients were predominantly white (74.2% for P+AI and 77.1% for P+FV patients). The initial dosing for palbociclib was 125mg/day in 85.4% (n=199) of P+AI and 79.2% (n=38) of P+FV patients. Among patients who received P+AI, PFR-12 was 69.8% and PFR-24 was 46.8% with median follow up time of 10.8 months and 36.8% of progression events. The SR-12 was 89.8% and SR-24 was 71.4%. For patients who received P+FV, PFR-12 was 43.5% and PFR-18 was 39.9% with a median follow up time of 7.6 months and 50.0% of progression events. The SR-12 was 76.3% and SR-18 was 65.0%.

Conclusions:
This study provides real-world assessment of treatment patterns and clinical outcomes of patients with HR+/ HER2- A/MBC who received palbociclib in combination with an AI or a FV in US community oncology settings. These findings demonstrate the benefit of palbociclib combination therapy in a diverse real world population.

Phase Ib/II study of capecitabine 7/7 schedule with neratinib in patients with HER2-positive metastatic breast cancer (MBC)

Rui Wang1, Jasmeet Singh1, Valentina Sterlin1, Michelle Goldstein1, Diana Lake1, Serena Wong1, Jose Baselga1, Larry Norton1 and Chau Dang1. 1Memorial Sloan Kettering Cancer Center, New York, NY.

Background: Neratinib (N) is a potent irreversible inhibitor of HER1, HER2, and HER4 and has been shown to have antitumor activity in patients (pts) with human epidermal growth factor receptor 2 (HER2) - positive breast cancer. A previous study of combination of neratinib with capecitabine (X) was associated with > G 3 diarrhea in > 20% of patients. Currently, the NALA study is evaluating this combination of N with X at standard schedule against control. X at 7 day on and 7 day off schedule (7/7) has been shown to be well-tolerated with less ≥G3 toxicities. We are conducting a phase Ib/II study of N with X (7/7) in pts with pretreated HER2+ MBC (NCT03377387). Methods: Eligible pts had HER2+ MBC, normal left ventricular ejection fraction (LVEF ≥ 50%); pts can have any and up to 4 prior chemotherapy-based treatments in phase Ib and II portions, respectively. Primary endpoints are to define maximum tolerated dose and efficacy in phase I and phase II portions, respectively. Secondary endpoints include safety and tolerability; exploratory endpoint is to quantify cell-free DNA to correlate with response for phase II portion. There were 4 cohorts for phase Ib with dose level 1 with starting dose of X at 1500 mg BID at 7/7 schedule with N at 240 mg daily. Results: As of July 1, 2018 8 pts have been enrolled in 2 cohorts. The median age is 63y (range: 57-79), and median ECOG is 0 (range: 0-1). 4 patients were treated at dose level 1 and 2 of 4 patients experienced dose-limiting toxicity with G3 diarrhea during cycle 1. Other significant toxicities included G3 hand foot syndrome (n=1), G3 fatigue (n=1) and G3 nausea (n=1). Three pts have now been treated at dose level -1 (X at 1000 mg twice daily 7/7 and N at 240 mg daily) and no ≥ G3 toxicities has been noted. Once MTD is reached, the phase II portion will occur to assess the efficacy and to further establish the safety and tolerability of capecitabine and neratinib at the MTD. Conclusions: The phase Ib/II study combining neratinib and capecitabine 7/7 is ongoing and updated result will be presented.
PROCLAIM-CX-072: Monotherapy for advanced triple negative breast cancer with skin metastases in a phase 1-2 trial of the PD-L1 probody therapeutic CX-072

Sylvia Adams¹, Erika Hamilton², Patrick A Ott³, Daniel Cho¹, Kevin Kalinsky⁴, Patricia LoRusso⁵, Matthias Will⁶, Vanessa Huels⁶, Beverly Benson⁶, Carmen Murias⁷ and Hendrik-Tobias Arkenau⁷. ¹Perlmutter Cancer Center, New York University School of Medicine, New York, NY; ²Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN; ³Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; ⁴Columbia University Medical Center, New York, NY; ⁵Yale University School of Medicine, Yale Cancer Center, New Haven, CT; ⁶CytomX Therapeutics, Inc., South San Francisco, CA and ⁷Sarah Cannon Research Institute UK Ltd, London, United Kingdom.

**Background:** Probody™ therapeutics are novel, fully recombinant antibody prodrugs designed to remain relatively inactive in healthy tissue and to be specifically activated by proteases in the tumor microenvironment. In this way, Probody therapeutics may broaden the therapeutic window for effective but potentially toxic anticancer agents. CX-072 is a Probody therapeutic directed against programmed death-ligand 1 (PD-L1) for the treatment of cancer patients. In a first-in-human, open-label, multicenter, dose-escalation, 3+3 design, phase 1-2 study, PROCLAIM-CX-072 (PRObody CLinical Assessment In Man) (NCT03013491), 22 patients were enrolled in the phase 1 dose escalation portion. Twenty patients were evaluable per RECIST v1.1. Three patients had confirmed partial response (15%), including a 39-year-old woman with stage IV triple negative breast cancer (TNBC) treated with 10 mg/kg CX-072 monotherapy whose disease had progressed on one previous line of chemotherapy for metastatic disease. Metastatic sites included extensive nodal disease and skin/chest wall lesions. The tumor was negative for PD-L1 expression, was microsatellite stable, and had a low tumor mutational burden (4 mutations/megabase). Positive results from the phase 1 study suggest that additional exploration of treatment with CX-072 monotherapy in the TNBC patient population is warranted.

**Dose expansion trial design:** The phase 2 dose expansion part of the PROCLAIM-CX-072 study will include enrollment of TNBC patients with skin metastases. Key inclusion criteria for patients in the TNBC cohort are as follows: naive to immunotherapy (PD-1/PD-L1 and CTLA-4 inhibitors), approved immune checkpoint inhibitor agents not available, histologically confirmed triple negative (estrogen receptor–, progesterone receptor–, and human epidermal growth factor receptor-2–negative cancer per ASCO-CAP guidelines), previously treated with 1 to 3 systemic chemotherapy regimens, and locally advanced and recurrent skin or subcutaneous metastases not suitable for surgical resection or radiotherapy. Patients will receive doses of 10 mg/kg CX-072 intravenously every 2 weeks. Efficacy will be evaluated using RECIST v1.1 and immune-related RECIST criteria. Safety and tolerability will be assessed based on the incidence and severity of adverse events (categorized by NCI CTCAE criteria, v4.03) and relationship to study drug. Other analyses will include pharmacokinetics, incidence of anti-drug antibodies against CX-072, exploratory analysis for immune response, and CX-072 activation in the tumor.

Profiling the early haematological dynamics and treatment modifications with palbociclib when used as first line treatment for ER-positive, HER2-negative metastatic breast cancer

Ajay Bhojwani1,2, Helen Flint1, Ben Hall1, Helen Wong1, Helen Innes1, Joanne Clifford1, Elyyaz Ahmed1, Zaf Malik1, Julie O’Hagan1, Shaun Tolan1, Alison Hall1, Khizar Hyatt1, Douglas Errington1, Farida Alam1, Peter Robson1, Nicky Thorp1, Susan O’Reilly1, Andrea Law1, Silivia Cicconi2, Richard Jackson2 and Carlo Palmieri1,2.

1Clatterbridge Cancer Centre NHS Foundation Trust, Liverpool, Merseyside, Switzerland and 2University of Liverpool, Liverpool, Merseyside, United Kingdom.

Background: Palbociclib plus endocrine therapy (ET) significantly increases progression free survival compared to ET alone. Within PALOMA2 neutropenia was the most common AE and reason for dose reductions. No real data exists regarding dose reductions (DRs), dose interruptions (DIs), toxicities and benefits of palbociclib.

Objective: To describe the early haematological dynamics, DRs/DIs with 1st line palbociclib in the context of a routine UK clinical practice.

Methods: A prospective record was maintained of all patients with ER-positive, HER2-negative metastatic BC registered on the Pfizer patient programme at the Clatterbridge Cancer Centre NHS Foundation Trust. The clinical records of all patients commenced on treatment between April and December 2017 were reviewed, and clinico-pathological information, haematological data & toxicity data recorded. Data lock was 31st March 2018.

Results: 48 patients received at least one cycle of treatment. The median age was 58, 29% (14/48) premenopausal & 71% (34/48) postmenopausal. 43% (21/48) had bone only disease with 42% (20/48) having visceral disease. The median number of cycles delivered 8 (range 2-11).

DRs: 18/48 (38%) patients had a total of 21 DRs; 14/18 (78%) had 1 DR to 100mg; 1/18 (5%) 1 DR to 75mg; & 3/18 (17%) 2 DRs to 75mg. Reasons for DRs: 13 neutropenia, 2 leukopenia, 1 thrombocytopenia, 2 fatigue, 1 poor appetite, 1 sore mouth & 1 non-specially unwell. DIs: occurred in 24/48 patients (50%). Details of DRs/DIs by cycle will be presented. 85% (41 of 48) patients remain on treatment with 59% (24/41) on 125mg; 34% (14/41) on 100mg & 7% (3/41) on 75mg. FBC were available for 41/48 (85%) cases & dynamics considered over the first 6 cycles using FBC at the time of planned treatment delivery.

Conclusion: These initial real world data are consistent with the PALOMA2 data. Baseline WCC & ANC show no significant difference between NDR and DR cases. Updated data will be presented as well as outcome data for first time.
GI toxicities in metastatic breast cancer: A comprehensive literature review

Tim Disher1, Muhaimen Siddiqui1, Debanjali Mitra2, Chris Cameron1, Lin Zhan2 and Shrividya Iyer2. 1Cornerstone Research Group, Inc, Burling, ON, Canada and 2Pfizer, New York, NY.

**Background**
Treatments for advanced or metastatic breast cancer (aBC/mBC) are associated with gastrointestinal (GI) toxicities. The objective of this study was to assess the association between GI toxicities in mBC/aBC and health-related quality of life (HRQoL) and economic burden.

**Methods**
We conducted a comprehensive literature search of the Cochrane Central Register of Controlled Trials (2017), NHS Economic Evaluation Database (2016), Embase (1988 – 2017 week 34), and Ovid MEDLINE (1946 to August 2017). Eligible studies evaluated an intervention/comparator treatment in adult patients (age ≥18 years) with aBC/mBC and reported a direct connection between GI toxicities (ie, diarrhea, constipation, nausea, vomiting) and HRQoL and economic evidence. All studies published from January 2000 to August 2017 were assessed for eligibility. Editorials, case reports, conference abstracts, and studies of early, locally advanced, or inflammatory BC were excluded. Abstract and title screening, and full-text screening were conducted by single reviewers. Data were extracted by a single reviewer and verified by a second. Results were synthesized narratively.

**Results**
Database searches identified 3,428 articles; an additional 16 articles were identified through other sources. Ninety-four studies underwent full-text review, of which 27 reported a direct connection between GI toxicities and HRQoL (n = 11) and economic burden (n = 19). Some studies reported both HRQoL and economic data.

Patients identified treatment-related adverse events (AEs), such as GI events, as an important aspect of treatment that can affect therapy choice, discontinuation, and switching. Generally, patients with mBC had lower HRQoL than other BC groups, and increasing toxicity was associated with a greater degree of HRQoL impairment. When patients were asked to rank which AEs they most wanted to avoid, only pain ranked higher than nausea and vomiting. In a willingness to pay study, women with mBC were willing to pay $3,894 (2014 USD) per year to avoid severe diarrhea and $3,211 to avoid severe nausea.

Gastrointestinal events were among the costliest class of AEs, with mean costs as high as $4,809 (2016 USD) per episode; costs increased by 24% if events were persistent or recurrent.

**Conclusions**
Gastrointestinal toxicities are common in patients with aBC/mBC and have significant consequences for HRQoL and system-level economic outcomes. Frequency and implications of GI effects of treatment regimens should be considered carefully during patient counseling, prescribing and coverage decisions in metastatic breast cancer.
Treat ER\textsuperscript{right} Canadian prospective observational study in HR+ advanced breast cancer: 3\textsuperscript{rd} interim analysis

Catherine Doyle\textsuperscript{1}, Nadia Califaretti\textsuperscript{2}, Susan Dent\textsuperscript{3}, Nayyer Iqbal\textsuperscript{4}, Mihaela Mates\textsuperscript{5}, Swati Kulkarni\textsuperscript{6}, Puneet Bains\textsuperscript{7}, Vivian Glenns\textsuperscript{8}, Sabrina R Perri\textsuperscript{9} and Stephen Chia\textsuperscript{10}. \textsuperscript{1}Deschênes-Fabia Breast Cancer Center, Quebec City, QC, Canada; \textsuperscript{2}Grand River Regional Cancer Center, Kitchener, ON, Canada; \textsuperscript{3}Ottawa Hospital Cancer Center, Ottawa, ON, Canada; \textsuperscript{4}Saskatchewan Cancer Agency, Saskatoon, AB, Canada; \textsuperscript{5}Kingston General Hospital, Kingston, ON, Canada; \textsuperscript{6}Windsor Regional Cancer Center, Windsor, ON, Canada; \textsuperscript{7}Lions Gate Hospital, North Vancouver, BC, Canada; \textsuperscript{8}North York General Hospital, North York, ON, Canada; \textsuperscript{9}Novartis Pharmaceuticals Canada Inc., Dorval, QC, Canada and \textsuperscript{10}BC Cancer Agency - Vancouver Cancer Center, Vancouver, BC, Canada.

Treat ER\textsuperscript{right} is the 1\textsuperscript{st} prospective observational study in Canadian HR+ HER2– advanced breast cancer patients currently receiving endocrine therapy (ET) alone or in combination with targeted therapy (TT) in the first, second or third line setting (NCT02753686).

**Methods:** This pre-planned interim analysis describes baseline characteristics, treatment patterns and safety/toxicity of patients enrolled in ET and ET+TT cohorts. At data cut-off (November 2017), 200 patients were enrolled from 24 sites since March 2016. The median follow-up time at data cut-off was 8.1 months and 182 patients were evaluable for this analysis.

**Results:**

**Conclusions:** The majority of patients enrolled (64%) were receiving endocrine-based targeted therapy (CDK4/6 inhibitor or mTOR inhibitor) combinations. ET+TT patients were younger with more visceral disease and liver metastases compared to patients receiving endocrine therapy alone. Real-world starting dose of targeted therapies appears to be lower than the approved full dose for 11% of patients receiving palbociclib and 28% of patients receiving everolimus. Incidence of reported all-grade adverse events appears to be lower than previously reported in randomized trials and may be a consequence of real-world under-reporting of adverse events as well as the heterogeneous nature of the treatment cohorts. There does however appear to be a trend toward increased incidence of adverse events in the ET+TT cohort compared to the ET cohort.
A phase 1 study of erlotinib and metformin in advanced triple negative breast cancer

Kathleen M Fenn1, Matthew A Maurer1, Shing M Lee2, Katherine D Crew1, Meghna S Trivedi1, Melissa K Accordino1, Dawn L Hershman1 and Kevin Kalinsky1. 1Columbia University Irving Medical Center, New York, NY and 2Mailman School of Public Health, Columbia University, New York, NY.

Background: The epidermal growth factor receptor (EGFR) is frequently overexpressed in triple negative breast cancer (TNBC). However, EGFR inhibitors have not shown efficacy as monotherapy in TNBC. One strategy for overcoming resistance to EGFR inhibition is concomitant inhibition of downstream signaling. Metformin is a LKB1-dependent AMPK activator that inhibits both MAPK and AKT signaling. The combination of the EGFR inhibitor erlotinib and metformin synergistically induces apoptosis in TNBC cell lines and decreases tumor burden in PTEN-null EGFR-amplified mouse xenograft models. We evaluated the combination of erlotinib and metformin in a phase 1 study of patients with advanced TNBC.

Methods: Patients with advanced TNBC who had received at least one prior line of therapy for metastatic disease were eligible. Erlotinib dose was fixed at 150mg daily. Metformin dose escalation was planned according to a 3+3 design, beginning at 850mg BID and escalating to 850mg TID. One de-escalation to 500mg BID was allowed. Dose-limiting toxicities (DLT) were assessed during the first five weeks of therapy. The primary objectives were to determine the maximum tolerated dose (MTD) of metformin with fixed dose erlotinib and to determine the potential for clinical benefit. Secondary endpoints were response rate, stable disease rate, and progression free survival. Pre- and on-treatment skin biopsies were collected to determine the effect of the study drugs on their respective cell signaling targets, particularly EGFR, AMPK, and mTOR.

Results: Between March 2013 and May 2015, nine patients were screened and eight were enrolled. Median age was 48 years (range 37-79). Median number of prior therapies for metastatic disease was 2.5 (range 1-6). No DLT events were reported in either of the dose escalation cohorts during the DLT assessment period. AEs occurring in three or more patients and all grade III AEs are reported in Table 1. Grade III diarrhea despite maximum supportive care required dose reduction of metformin from 850mg TID to 850mg BID in one patient. Grade III rash led to study withdrawal in one patient. No grade IV AEs were reported. Per RECIST v1.1, the best observed response was stable disease in two patients (25%). Median time on study was 2.0 months (range 1.2-3.0). Skin biopsy marker assessment is ongoing and will be reported.

Conclusion: The combination of erlotinib and metformin was generally well tolerated in a population of pre-treated metastatic TNBC patients. No unexpected toxicities occurred. While no responses were achieved, stable disease was observed in patients who received this non-chemotherapy combination.

Real world treatment patterns and outcomes of patients receiving palbociclib plus aromatase inhibitor in the United States: Sub-groups analysis based on age, performance status and sites of metastases from the IRIS study

Gavin Taylor-Stokes¹, Debanjali Mitra², John Waller¹, Katie Gibson¹, Gary Milligan¹, Lin Zhan² and Shrividya Iyer². ¹Adelphi Real World, Bollington, United Kingdom and ²Pfizer, New York, NY.

Background: Ibrance Real World Insights (IRIS) is a multi-country study aimed to describe clinical characteristics, treatment patterns and clinical outcomes of patients receiving palbociclib plus aromatase inhibitor. Previously the results on the overall population within the US have been communicated. The current analysis focuses on subgroups stratified by age, performance status and visceral status.

Materials and methods: A retrospective chart review of HR+/HER2- ABC/MBC patients who received palbociclib plus aromatase inhibitor as initial endocrine based therapy for their advanced disease was conducted between June and October 2017. Physicians completed electronic case report forms, extracting data on patient demographics, clinical characteristics, treatment history/patterns and clinical outcomes. Progression free and survival rates at 12 and 24 months were estimated via Kaplan-Meier analysis.

Results: Data for the US are reported here. In total 63 physicians completed 360 eCRFs with a mean follow up time since palbociclib initiation of 12 months. Majority of the patients were >65 years (53%), and had ECOG status of 0 (30%) or 1 (56%). Overall 293 (81%) patients had metastatic disease, of which 50% had visceral metastases. Across all sub-groups, majority of patients prescribed an initial palbociclib dose of 125mg did not require a change of dose while on treatment. The 12-month and 24-month progression free and overall survival rates across subgroups are presented in Table 1. Patients with a performance status of ECOG=1 had a slightly lower progression and survival rates at 12 and 24 months compared to those with a score =0. Likewise, patients with visceral disease were observed to have slightly lower progression free and survival rates than others.

Table 1: Clinical Outcomes for the different sub-groups.

Conclusions: The analysis indicates consistent trends in different clinical outcomes were observed with palbociclib plus aromatase inhibitor across patients sub-groups based on age, performance status and visceral metastases.
The efficacy and safety analysis of the treatments of everolimus and exemestane combination in 101 metastatic breast cancer patients: Real-life experience from Turkey

Ahmet Bilici¹, Serkan Menekse², Semih Akin³, Mustafa Degirmenci⁴, Omer Fatih Olmez⁵, Nilufer Avci⁶, Teoman Sakalar⁷, Deniz Tural⁸, Muhammed Ali Kaplan⁹, Ozgur Tanriverdi⁹, Irem Bilgetekin¹⁰ and Ruchan Uslu¹. ¹Medipol University, Medical Faculty, Istanbul, Turkey; ²Bagcilar Education and Research Hospital, Istanbul, Turkey; ³Ege University, Medical Faculty, Izmir, Turkey; ⁴Izmir Tepecik Education and Research Hospital, Izmir, Turkey; ⁵Ali Osman Sonmez Oncology Hospital, Bursa, Turkey; ⁶Erçiyes University, Medical Faculty, Kayseri, Turkey; ⁷Bakirkoy Sadi Konuk Education and Research Hospital, Istanbul, Turkey; ⁸Dicle University, Medical Faculty, Diyarbakir, Turkey; ⁹Mugla Sitki Kocman University, Medical Faculty, Mugla, Turkey and ¹⁰Gazi University, Medical Faculty, Ankara, Turkey.

Background: Endocrine treatment and chemotherapy are a treatment options for patients with hormone receptor (HR) positive and HER2-negative metastatic breast cancer (MBC). However, response to first-line hormone treatment could not obtained in all patients, and even patients who havea response will eventually relapse. After disease progression, second-line hormonal treatment options are used sequentially. Everolimus with exemestane has demonstrated promising activity in patients with HR-positive HER2-negative endocrine-resistant MBC with respect to the results of the BOLERO-2 study. In the present study, we aimed to evaluate the efficacy and safety of this combination in the real-life clinical setting for the unselected population in Turkey.

Material and Methods: One hundred and one patients with HR-positive HER-2 negative MBC progressing after prior endocrine treatment who were treated with everolimus with exemestane were retrospectively analyzed. The tolerability and efficacy of this combination were evaluated in the unselected Turkish patients. Results: Among 101 patients, 45% of patients had visceral and 50% patients had only bone metastasis. Everolimus with exemestane treatment was administered as a second-line in 21.3% of patients, third-line in 40.4% and forth-line and later in 38.2%. The objective response rate was 24.7% (CR+PR) and stable disease was obtained in 37.7% of patients. At the median follow-up time of 13.5 months, the median progression-free survival (PFS) time and 1-year PFS were 13.8 months and 57.2%, while the median overall survival (OS) interval and 1-year OS were 40 months and 85%. The median treatment duration was 8.3 and 6.5 months for exemestane and everolimus, respectively. The most frequent reason for discontinuation of treatment were disease progression (39%). Moreover, the most common adverse events (AE) causing permanent discontinuation were stomatitis (3%) and pneumonitis (3%). A total of 81 % of patients experienced at least one AE of any grade, 25% of patients at least one grade 3 or 4 AE. Due to AEs, everolimus dosage was reduced to 5 mg in 16 (15.8%) of patients. Conclusions: Our findings confirmed that the combination of everolimus with exemestane was the safe and effective treatment options for patients with HR-positive HER-2 negative MBC after second or later lines treatments.
Treatment patterns and sequences among pre-menopausal women with HR+/HER2- metastatic breast cancer: A chart review study

Anand A Dalal¹, Debbie Goldschmidt², Hela Romdhani³, Sneha Kelkar², Annie Guerin³, Helen Wang², Nicola Caria¹, Amrita Sawhney¹ and Joyce O'Shaughnessy⁴. ¹Novartis Pharmaceuticals Corporation, East Hanover, NJ; ²Analysis Group, New York, NY; ³Analysis Group, Montreal, QC, Canada and ⁴Baylor University Medical Center, Dallas, TX.

Background: Recently, a novel class of treatments, CDK4/6 inhibitors, has been approved, and is now recommended for pre-menopausal women with HR+/HER2- metastatic breast cancer (mBC). This study examined prevailing treatment patterns and sequencing among premenopausal women with mBC treated in clinical practice.

Methods: Patient-level data were collected from patient charts in May 2018 from 30 oncologists, mostly from community practice, in the US. Treatment sequences and patterns were assessed for pre-menopausal women diagnosed with HR+/HER2- mBC between January 2015 and January 2017 (with a minimum of 1 year of follow-up).

Results: Data were collected on 201 pre-menopausal women with HR+/HER2- mBC. In first-line therapy for mBC, 52.7% of the patients received a CDK4/6 inhibitor-based regimen, 23.4% received endocrine monotherapy, 20.9% received a chemotherapy-based regimen, and the remaining 3.0% received an everolimus-based regimen. The majority of patients who received a CDK4/6 inhibitor received it in combination with an AI (73.6%), fulvestrant (11.3%), or tamoxifen (6.6%). Approximately half of all patients (51.2%) received an ovarian suppression agent during first-line therapy. Overall, median time on treatment from Kaplan Meier (KM) analysis for first-line therapy was 16.1 months. Most common reason for discontinuing first line was disease progression or suboptimal response (79.0% of patients who discontinued); another common reason was the completion of the planned duration of therapy (12.6%).

Among the 106 patients who received a CDK4/6 inhibitor in the first line, median time on treatment from KM analysis was 26.8 months. Main reason for CDK4/6 inhibitor discontinuation was disease progression or suboptimal response (90.2% of patients who discontinued).

For the 109 patients for whom we observed a second-line therapy, treatment sequences are presented in Table 1. Median time on treatment for second and third line therapy was 9.6 and 7.8 months, respectively.

Conclusion: Following the introduction of novel CDK4/6 inhibitor treatments in the mBC setting, we observed that approximately half of pre-menopausal patients received a CDK4/6-based regimen in the first line of therapy.

Abemaciclib after prior palbociclib exposure in patients with metastatic hormone-receptor positive (HR+)/HER2- breast cancer

Seth A Wander¹, Laura M Spring¹, Casey R Stein¹, Megan Yuen¹, Mark Zangardi¹, Joyce O'Shaughnessy² and Aditya Bardia³. ¹Massachusetts General Hospital Cancer Center, Boston, MA and ²Texas Oncology-Baylor Charles A. Sammons Cancer Center, Dallas, TX.

Introduction: The advent of cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) has transformed the clinical practice of HR+/HER2-metastatic breast cancer. Palbociclib, ribociclib, and abemaciclib have been approved in conjunction with anti-estrogens, while abemaciclib has also been approved as monotherapy based on single agent activity in the MONARCH-1 trial (objective response rate/ORR: 19.7% and median progression-free-survival/PFS = 6.0 months; Dickler M et al CCR 2017). However, there is limited insight into the mechanisms governing resistance to CDK 4/6i and the potential utility of continued CDK4/6i after progression on a prior CDK 4/6i-based therapy.

Methods: We evaluated the clinical outcomes of patients with metastatic HR+/HER2- breast cancer who had received abemaciclib following an initial course of palbociclib-based therapy at our institution. In addition, we conducted genomic analysis utilizing next-generation sequencing of tissue samples and blood (cell-free DNA/cfDNA analysis) where available.

Results: From June, 2014 through July, 2018, a total of 49 patients received abemaciclib, and 14 patients had prior palbociclib exposure. One patient was deceased shortly after initiating abemaciclib and one patient was lost to follow-up. Among the 12 remaining patients, eight had sequential courses of CDK4/6-based therapy, while four patients had at least one intervening non-CDK 4/6i based regimen. At data-cutoff of 8/15/2018, five patients (41.7%) had early progression on abemaciclib (PFS equal to or less than 120 days) while three (25%) patients had ongoing benefit (PFS greater than 120 days, two of three actively on therapy). Three additional patients had recently initiated abemaciclib therapy (less than 120 days prior to current analysis). Preliminary analysis of baseline cfDNA results in patients with early progression on abemaciclib therapy after prior CDK4/6i revealed the presence of RB1 mutation, FGFR1 amplification, and TP53 mutation, among others. Additional analyses with mature clinical data (including updated PFS and ORR), toxicity assessment during secondary CDK4/6i exposure, and further analysis of genomic sequencing results will be provided at the meeting.

Conclusions: The majority of patients had early disease progression on abemaciclib after prior exposure to CDK4/6i suggesting potential cross-resistance to CDK4/6i mediated by common drivers. However, a subset of patients derived clinical benefit with continued exposure to CDK4/6i, highlighting the need for additional research to evaluate potential predictive biomarkers and guide rational utilization of continued CDK4/6 blockade in metastatic HR+/HER2- breast cancer.
Evaluation of multiple transcriptomic gene risk signatures in male breast cancer

**Introduction:** Male breast cancer (MBC) is a rare disease accounting for less than 1% of all breast cancers (BC) and 1% of all cancers in males. The clinical management is largely extrapolated from female BC. Several multigene assays are increasingly used to guide clinical treatment decisions in female BC, however there is little data on the utility of these tests in MBC.

**Methods:** Here we present the gene expression results of 380 M0, ER+ve, HER2-ve MBCs enrolled in the Part 1 (retrospective joint analysis) International Male Breast Cancer Program of 1483 patients diagnosed between 1990-2010 (Cardoso et al. Annals of Oncology, 2018). Using a custom Nanostring™ panel comprised of the genes from the commercial risk tests Prosigna®, OncotypeDx® and Mammaprint®, risk scores and intrinsic subtyping data were generated to recapitulate the commercial tests as described by Bayani and Yao et al (npjBreast Cancer, 2017). Survival outcomes by risk classification were analyzed using Cox models with time-dependent covariates when the proportional hazard assumption was not met and adjusted for clinical and treatment variables.

**Results:** Prosigna-like risk scores identified 99 (26.1%) as low-risk, 159 (41.8%) as intermediate-risk, and 122 (32.1%) as high-risk. Using the TAILORx cut-off (25) for OncotypeDx-like risk of recurrence scoring, 158 (41.6%) were identified as low-risk, while 222 (58.4%) were identified as high-risk. MammaPrint-like results identified 175 (46.1%) as low-risk and 205 (53.9%) as high-risk. Overall, patients classified as high-risk had higher grade, more nodal involvement, larger tumors, and more frequently treated with chemotherapy than low-risk patients. Survival analyses demonstrated clear clinical utility for each test, showing patients at high-risk with poor relapse-free survival (RFS) as compared to patients classified as low-risk: Prosigna-like RFS at 3-years (HR=2.20, 95% CI, 1.28-3.80); Oncotype-like RFS at 3-years (HR=1.92, 95% CI, 1.17-3.17); MammaPrint-like RFS (HR=1.51, 95% CI, 1.00-2.27); with similar findings for distant relapse-free survival (DRFS) and overall survival (OS). Across outcomes and all gene signatures, patients with concordant Low/Low risk classification had better prognosis than those with discordant High/High risk classification. PAM50 intrinsic subtyping identified 147 (38.7%) as Luminal A, 57 (15.0%) as Luminal B, 80 (21.1%) as Her2-enriched and 96 (25.3%) as Basal-like; showing overall 34.5% concordance to clinic-pathological subtyping by central pathology (95% CI, 29.7%-39.5%). Comparison between the tests in the MBC cohort and a comparable cohort of female BC from the Tamoxifen Exemestane Adjuvant Multinational (TEAM) trial processed in the same way will be presented.

**Conclusion:** Common transcriptomic assays designed to assess residual risk, validated in female BC, provide similar information
in male BC patients. Not surprisingly, disagreement between test results at the individual patient level was observed. To our knowledge, this is the largest study of MBC assayed to generate risk scores of the current commercial BC tests to demonstrate their clinical utility and their differences and similarity to female BC. This work has been funded by the Breast Cancer Research Foundation (BCRF).
Tumor subtypes and survival in male breast cancer: SEER 2010-2014

Julieta Leone¹, Rachel A Freedman², Ariel O Zwenger¹, Nancy U Lin², Sara M Tolaney², Carlos T Vallejo¹, Bernardo A Leone¹, Eric P Winer² and Jose P Leone². ¹Grupo Oncológico Cooperativo del Sur (GOCS), Neuquén, Argentina and ²Dana-Farber Cancer Institute, Boston, MA.

**Background:** Male breast cancer (MaBC) is an uncommon disease, and population-based information regarding prognostic factors is limited. Most MaBC are hormone receptor (HR) positive, however, the association of tumor subtypes with overall survival (OS) and breast cancer-specific survival (BCSS) is unclear. The aim of this study was to analyze the characteristics of each tumor subtype and its impact on OS and BCSS.

**Methods:** Using Surveillance, Epidemiology, and End Results (SEER) data, we identified men with invasive breast cancer between 2010 and 2014 with known estrogen receptor and progesterone receptor (together HR) status and human epidermal growth factor receptor 2 (HER2) status. Tumor subtypes were classified as: HR+/HER2-, HR+/HER2+, HR-/HER2+ and triple negative (TN). We examined tumor subtypes by patient (pt) characteristics and performed multivariate Cox proportional hazards analyses to determine the associations of each variable with OS and BCSS.

**Results:** We included 1508 pts with a median follow-up of 24 months (range 0-60). Median age was 65 years (range 26-97). At diagnosis, 86.6% of tumors were ductal, 97.1% HR+, 42.1% T1, 55.7% N0, 7.9% M1. Tumor subtype distribution was: 85.5% HR+/HER2-, 11.6% HR+/HER2+, 0.9% HR-/HER2+ and 2% TN. Compared with other subtypes, pts with TN tumors had higher grade disease, presented with more advanced stage and died more often from breast cancer (all p<0.0001); whereas pts with HR+/HER2- tumors were older (p=0.02) and more often white (p=0.02). In univariate analysis, OS at 5 years for all HER2- and all HER2+ was 74.2% and 64.1%, respectively (p=0.002); while BCSS at 5 years for all HER2- and all HER2+ was 88.4% and 78.8%, respectively (p=0.009). Of all subtypes, TN had the worst OS and BCSS (p<0.0001). Breast cancer was the cause of death in 43.7% of HR+/HER2-, 54.2% of all HER2+ and 100% of TN (p<0.0001). In multivariate analyses for OS, older pts (Hazard ratio [HaR] 3 vs. <50 years; p=0.001), stage IV (HaR 9 vs. stage I; p<0.001), HR+/HER2+ tumors (HaR 1.9 vs. HR+/HER2--; p=0.003), TN tumors (HaR 8.5 vs. HR+/HER2--; p<0.001) and unmarried pts (HaR 1.9 vs. married; p=0.002) had significantly worse survival. In multivariate analyses for BCSS, stage IV (HaR 25.7 vs. stage I; p<0.001), HR+/HER2+ tumors (HaR 2.1 vs. HR+/HER2--; p=0.019), TN tumors (HaR 17 vs. HR+/HER2--; p<0.001) and unmarried pts (HaR 2.2 vs. married; p=0.009) had significantly worse survival.

**Conclusion:** We observed significant differences in outcomes by tumor type in men with breast cancer which mirror those previously observed for women with breast cancer. Among the limited numbers of men with HER2+ and TN disease in our sample, outcomes were poor, suggesting possible under-treatment, aggressive tumor biology, and/or more advanced of disease at presentation. Studies to better understand the inferior survival for men with these subtypes are warranted and efforts to ensure appropriate treatment are paramount.
The role of lumpectomy and radiation therapy in men 70 years of age and older with early breast cancer on hormone therapy: A NCDB analysis

Sarah B Bateni¹, Mili Arora¹, Megan E Daly¹, Richard J Bold¹, Robert J Canter¹ and Candice AM Sauder¹. ¹University of California Davis Medical Center, Sacramento, CA.

Background: Current consensus guidelines for the treatment of male breast cancer are driven by female-only clinical trials despite data suggesting distinct biologic, clinicopathologic, and prognostic differences between male and female breast cancer patients. This includes a recent retrospective multicenter analysis showing greater overall survival among male breast cancer patients who underwent lumpectomy with radiation therapy (RT), compared to total mastectomy or lumpectomy alone. In light of these findings and the CALGB 9343 trial performed in women, we sought to evaluate if survival was also equivalent in men ≥70 years old with early stage breast cancer treated with hormone therapy and lumpectomy with or without radiation therapy (RT), as shown in women.

Methods: We performed a retrospective analysis of 752 stage I (T1N0M0), estrogen receptor (ER) positive male breast cancer patients ≥70 years of age who were treated with hormone therapy and underwent lumpectomy with or without RT or total mastectomy (without RT) from the National Cancer Database (NCDB) between the years 2004 to 2014. Chi-squared, Kruskal-Wallis, and analysis of variance tests were used to compare demographic and clinicopathologic differences between groups. Multivariable Cox proportional hazards regression analysis was used to compare overall survival between treatment groups, controlling for demographic and clinicopathologic differences.

Results: Most patients underwent total mastectomy (67.4%), with only 32.6% treated with lumpectomy. Of those who underwent lumpectomy, 72.6% (n=178) underwent adjuvant RT. There were significant differences in age, tumor size, histology, grade, surgical margins, nodal surgery, and chemotherapy between patients who underwent lumpectomy without RT, lumpectomy with RT, and total mastectomy (p<0.05). Lumpectomy without RT patients were older (78.9 vs. 76.0 & 76.9 years, p<0.01), more frequently presented with invasive ductal carcinoma (77.6% vs. 71.3% & 85.4%, p<0.0001), and less frequently underwent axillary nodal surgery including sentinel lymph node biopsy (71.7% vs. 91.6% & 94.9%, p<0.0001) compared to lumpectomy with RT and total mastectomy patients. In multivariate analysis, there were no significant differences in overall survival for lumpectomy without RT, lumpectomy with RT (HR 0.71, 95%CI 0.39-1.27, p=0.25), and total mastectomy alone (HR 0.92, 95%CI 0.55-1.56, p=0.76). Older age, higher Charlson-Deyo comorbidity scores, and poorly differentiated tumors were associated with poorer overall survival, while treatment at an academic/research center was associated with improved overall survival (p<0.05).

Conclusion: In this national sample of elderly ER positive male breast cancer patients with early disease on hormone therapy, lumpectomy alone was associated with equivalent survival compared to lumpectomy with RT and total mastectomy alone. These results suggest that breast conserving surgery without radiation therapy is appropriate for this subset of male breast cancer patients and greater adoption by breast surgeons should be considered.
Male breast cancer: Tumour characteristics and treatment compared with females in Australia – 99,768 breast cancers over a 10 year period

Chan Arlene¹,², Lomma Chris¹, HuiJun Chih² and Peter Willsher¹. ¹Breast Cancer Research Centre - WA, Perth, Western Australia, Australia and ²Curtin University, Perth, Western, Australia.

Introduction
Stage and tumour characteristics in males with early breast cancer (EBC) differ from those in females. Guidelines recommend that treatment of males with EBC should be based on evidence derived from clinical trials in females but some studies suggest men may be undertreated. We assessed tumour characteristics and adjuvant treatment in Australian males as recommended by NCCN guidelines.

Methods
Using data collected prospectively in the BreastSurgANZ Quality Audit - society of breast surgeons in Australia and New Zealand. Membership requires entry of tumour and treatment details of all breast cancer patients managed by individual surgeons onto an online secure database. No outcome data is collected. The collected information is bound by the National Privacy Principles of both countries. Patients diagnosed with EBC from 1 October 2006 to 30 September 2016 were analysed. The study period was chosen as it corresponds with the availability of trastuzumab and contemporary chemotherapy regimens. Comparisons between males and females were made using chi-square test, significance was considered with alpha of 0.05.

Results
There were a total of 99,768 episodes, comprising 585 (0.6%) males (544 invasive; 41 DCIS) and 99,183 (99.4%) females (85,596 invasive; 13,525 DCIS; 62 unk). Mean age (range) 68y (25-94) males; 61y (15-102) females. Bilateral synchronous cancer in 6 (1%) males, 3636 (3.7%) females. Histology was ductal/lobular/other in 85%/2%/13% males; 76%/12%/12% females. DCIS in 7% males, 14% females. Triple negative (2% males, 11% females), hormone receptor positive (HR+ - 94% males, 82% females), HER2 positive (7% males, 13% females). Node positive 44% males, 35% females. No breast surgery was performed in 1.9% males, 1.3% females. Where breast surgery was done, complete local excision/mastectomy in 7%/90% males, 55%/40% females. In regard to axillary procedures; 632 were done in males with sentinel node biopsy (SLN) 53%, axillary dissection (AD) unk 3%; 100,187 done in females with SLN 65%, AD 33%, unk 2%. Table 1 shows the rate of adherence to NCCN February 2018 guidelines.

C - chemotherapy, T – trastuzumab, E – Endocrine, TR – treatment received

Discussion
In this Australian study, male breast cancer accounted for only 0.6% of all cases seen over the 10yr period. In line with other
studies, invasive lobular cancer, triple negative and HER2 positive disease was infrequently seen in males, but with a higher likelihood of being node positive. There were no cases of medullary carcinoma in males but a higher than previously reported incidence of DCIS. Males with HR+, HER2-, node positive EBC were significantly less likely to receive chemotherapy and endocrine treatment, with all other subgroups showing similar systemic treatment for both genders.
Clinical characteristics and survival of patients with male breast cancer: The Mayo Clinic experience

Siddhartha Yadav¹, Roberto A Leon-Ferre¹, Rafael E Jimenez¹, John R Hawse¹, Tina J Hieken¹, Fergus J Couch¹, Judy C Boughey¹ and Kathryn J Ruddy¹. ¹Mayo Clinic, Rochester, MN.

Background:
Male breast cancer (MBC) is rare, and usually managed by extrapolation from female breast cancer. We report on the characteristics and survival outcomes of MBC patients from Mayo Clinic Rochester (MCR).

Methods:
Medical records of MBC patients treated at MCR during a 25-year period (1990-2015) were reviewed. Demographic variables, tumor characteristics, recurrences, and overall survival (OS) were collected. Progression free survival (PFS) and OS were estimated by the Kaplan-Meier method. Multivariate Cox-proportional hazard regression was used to identify predictors of OS.

Results:
One hundred sixty-seven patients were included in the final analysis, with a median follow-up of 58 months after diagnosis. Baseline characteristics are presented in Table 1. Eighty percent of patients with ER-positive tumors received endocrine therapy. Among men with stage I-III disease, approximately 90% underwent mastectomy, and 44% received adjuvant chemotherapy. The 5-year locoregional and distant recurrence rates for patients with stage I-III disease were 4.4% and 21.5%, respectively. The 5-year PFS and OS for patients with stage I-III disease were 65.5% and 80.1%, respectively. In a multivariate analysis assessing predictors of OS in patients with stage I-III disease, older age (HR 1.05; 95% CI: 1.02 – 1.09), stage II (HR 11.06; 95% CI: 3.84 – 31.85) or stage III disease (HR 14.74; 95% CI (3.99 – 54.45), and omission of surgery (HR 45.33; 95% CI: 3.97 – 517.32) were associated with poorer OS, while endocrine therapy (HR 0.21, 95% CI: 0.09 – 0.51) was associated with better OS. ER, PR, HER2 and grade were not independently prognostic.

The median OS for stage IV patients was 10 months, though this 11-man cohort was too small to allow assessment of prognostic factors in advanced male breast cancer.

Conclusions:
MBC remains an understudied condition. Prognostic factors in this stage I-III disease are consistent with those identified in other MBC retrospective cohorts. Prospective studies are needed to better understand the unique clinical features of MBC, and to improve outcomes, particularly for advanced disease.

Breast conservation surgery in male breast cancer: A systematic literature review

Carla S Fisher¹, Lucy de la Cruz², Shivani Joshi³, Trina-Jo Mah³, Stephanie Blankenship⁴ and Paul Thiruchelvam³. ¹Indiana University School of Medicine, Indianapolis, IN; ²Perelman School of Medicine, Philadelphia, PA; ³Imperial College Healthcare, London, United Kingdom and ⁴Washington University at St. Louis School of Medicine, St. Louis, MO.

BACKGROUND
Male breast cancer (BC) incidence is low and management is extrapolated from female BC. Breast conservation surgery (BCS) is commonly used for female BC, however, mastectomy remains the most frequently used surgical procedure for male breast cancer. We performed a literature review to assess the use of BCS in male BC as well as outcomes following BCS.

METHODS
A systematic literature review identified peer-reviewed articles in PubMed evaluating male BC and surgery. Abstracts were screened to identify studies that measured overall survival (OS), disease-free survival (DFS), or local recurrence (LR) in patients undergoing BCS. For all studies, we extracted the total number of patients and number of BCS cases. Of patients undergoing BCS, we further extracted mean age, mean follow-up time, clinical stage, type of axillary surgery [sentinel lymph node biopsy (SLNB), axillary lymph node dissection (ALND)], radiation therapy, hormonal therapy, and chemotherapy. Weighted averages, based on number of patients in each study, were performed for LR, DFS and 5-year OS. The time period for LR and DFS was the duration of follow-up time for each study.

RESULTS
The literature search yielded 4341 articles. Twelve studies published from 1998 to 2016 met the inclusion criteria and were selected for the systematic literature review. Among the 12,616 male breast surgery cases included, 1,633 (12.9%) underwent BCS. Only patients who underwent BCS were included in our analysis. The mean follow-up time was 54.4 months and mean age was 62.4 with stage II as the most common presentation. Two studies reported that 50-71.4% of patients underwent SLNB and 4 studies reported ALND in 14.3-100%. Seven studies reported that adjuvant radiation therapy was administered in 12.0-100% of 474 total patients undergoing BCS. Four studies reported use of hormonal therapy in 73.8-100% of patients. Four studies reported use of chemotherapy in 25-66.7% of patients. Seven studies reported LR among 122 patients, with a weighted average 11.8%. Four studies reported on 5-year OS in 1511 patients, with a weighted average of 85.8%.

CONCLUSION
While less commonly used than mastectomy, BCS can be considered a safe alternative in the surgical treatment of male BC. We have demonstrated that the use of adjuvant radiation following BCS is variable in this patient group. Future research should focus on better standardization of local therapy for male BC and improved reporting of outcomes.
METRIC: A randomized international phase 2b study of the antibody-drug conjugate (ADC) glembatumumab vedotin (GV) in gpNMB-overexpressing, metastatic, triple-negative breast cancer (mTNBC)

Linda T Vahdat, Andres Forero-Torres, Peter Schmid, Kimberly Blackwell, Melinda L Telli, Michelle Melisko, Esther Holgado, Volker Moebus, Javier Cortes, Louis Fehrenbacher, Alberto J Montero, Cynthia Ma, Rita Nanda, Gail S Wright, Yi He, Rebecca G Bagley, Abdel Halim, Christopher D Turner, and Denise A Yardley.

1 Weill Cornell Medical College, New York; 2 University of Alabama, Alabama; 3 Barts Cancer Institute, London, United Kingdom; 4 Duke University Medical Center, Durham; 5 Stanford University School of Medicine, Stanford; 6 University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco; 7 Ramon y Cajal University Hospital, Madrid, Spain; 8 Klinikum Frankfurt Hoechst, Frankfurt, Germany; 9 Kaiser Permanente, Vallego; 10 Cleveland Clinic, Cleveland; 11 Washington University, St. Louis; 12 University of Chicago, Chicago; 13 Florida Cancer Specialists, New Port Richey; 14 Celldex Therapeutics, Hampton and 15 Sarah Cannon Research Institute/Tennessee Oncology, Nashville.

Background
gpNMB is an internalizable transmembrane protein overexpressed in ~40% of TNBC, and associated with a worse prognosis. Preclinical data implicates gpNMB in tumor invasion and metastasis. GV is a novel ADC designed to deliver monomethyl auristatin E (MMAE) to gpNMB-overexpressing cells. Prior phase 1/2 studies suggested promising activity of GV in gpNMB-overexpressing TNBC.

Methods
In the METRIC trial (NCT#01997333), patients (pts) with mTNBC were randomized 2:1 to GV (1.88 mg/kg IV q21 days) or capecitabine (2,500 mg/m² PO daily d1-14 q21 days) until disease progression or intolerance. Key eligibility criteria included: gpNMB over-expression (>25% tumor cells positive by central immunohistochemistry of archival tissue); estrogen and progesterone receptor expression <10% and HER2 negative; ECOG 0-1; prior taxane; prior anthracycline exposure (if indicated); <2 chemotherapy regimens for advanced BC. The primary endpoint was progression-free survival (PFS) per independent, blinded central review using RECIST 1.1. Secondary endpoints included overall survival (OS), objective response rate (ORR), duration of response (DOR), safety, and pharmacokinetics. The trial had 85% power to detect a PFS hazard ratio of 0.64 with two-sided \( \alpha = 0.05 \).

Results
From Feb 2014 to Aug 2017, 327 women were randomized at 120 institutions to GV (n=218) or capecitabine (n=109). Pretreatment characteristics were well balanced between arms: median age of 55 years; 77% visceral disease; 2.4 years median duration of disease at study entry; 1 median prior anticancer regimen for metastatic disease. At the cut-off for final data analysis (Nov 30, 2017), 21 pts remained on treatment and 98 pts were alive. For GV vs. capecitabine based on independent central review, median PFS was 2.9 (95% CI: 2.8, 3.5) vs. 2.8 (95% CI: 1.6, 3.2) months (HR=0.95; p=0.76); median OS was 8.9 (95% CI: 7.9, 10.5) vs. 8.7 (95% CI: 6.9, 10.8) months (HR=1.06; p=0.73); ORR was 16% (95% CI: 11.1, 22.4) vs. 15% (95% CI: 8.6, 23.5); and median DOR was 5.6 (95% CI: 3.0, 7.8) vs. 4.2 (95% CI: 3.0, 12.2) months. A post-hoc subgroup analysis suggested the greatest benefit from GV was in potentially taxane-sensitive disease (i.e., not previously rechallenged or >6 months progression-free interval following last taxane). The incidence of grade ≥3 treatment-related adverse events (TRAEs) was 58% in the GV arm and 37% in the capecitabine arm. The most common grade ≥3 TRAEs were neutropenia (27%), rash (15%), and leukopenia (9%) in the GV arm, and diarrhea (14%) and palmar-plantar erythrodysaesthesia (8%) in the capecitabine arm. There was 1 fatal TRAE of neutropenic sepsis in the GV arm and none in the capecitabine arm.

Conclusion
The METRIC study evaluating GV in mTNBC did not meet the primary efficacy endpoint of improved PFS over capecitabine. While anticancer activity was seen with GV, it was comparable to capecitabine with no therapeutic advantage of GV in terms of ORR, PFS, or OS. The safety profile of GV was consistent with prior experience with no new safety signals identified.
Activity of larotrectinib, a highly selective inhibitor of tropomyosin receptor kinase, in TRK fusion breast cancers

Funda Meric-Bernstam, Neerav Shukla, Nir Peled, Yosef Landman, Adedayo Onitilo, Sandra Montez, Nora C Ku, David M Hyman, Alexander Drilon and David S Hong. 1 The University of Texas MD Anderson Cancer Center, Houston, TX; 2 Memorial Sloan Kettering Cancer Center, New York, NY; 3 Institute of Oncology, Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel; 4 Soroka Cancer Institute, Ben Gurion University, Beer Sheva, Israel; 5 Marshfield Clinic Weston Center, Weston, WI and 6 Loxo Oncology, Inc., South San Francisco, CA.

Background: Tropomyosin receptor kinase (TRK fusions) involving the genes NTRK1, NTRK2, and NTRK3 occur in a broad range of malignancies including breast cancers (BC) with secretory features. Larotrectinib, the first selective TRK inhibitor in clinical development, has demonstrated an overall response rate of 75% by independent radiology review across various solid tumors, with a favorable safety profile. Here we report on a case series of TRK fusion BC patients treated with larotrectinib alone or in combination.

Methods: Patients were treated with oral larotrectinib in the NAVIGATE global phase II study or in single-patient compassionate-use protocols. All patients received the Phase 2 dose of 100mg BID on a continuous 28d schedule. Efficacy was evaluated using RECIST v1.1.

Results: As of June 2018, 5 TRK fusion BC patients had been treated, all with secretory characteristics, but diverse ER/PR/HER2 positivity (Table); 2 patients were triple negative. Four patients harbored ETV6-NTRK3 fusions. Larotrectinib treatment yielded a response rate of 80% (4/5 PRs). All responses occurred within the first 2 cycles of therapy and cancer-related symptoms resolved rapidly. No treatment-related Grade ≥3 adverse events have been reported.

Patient 2 (14 yr) presented with a recurrent fungating mass (10.4x8.5 cm) having failed multiple rounds of chemotherapy. Significant reduction in tumor size was noted after one week of larotrectinib treatment with near complete resolution after 2 months.1 Patient 3 (37 yr) had extensive involvement of the lung and pleura, bilateral pleural effusions, peritoneal infiltration with ascites, severe dyspnea with PS=3. There was rapid improvement with larotrectinib treatment and the patient was PS=1 after 2 weeks. At 6 weeks, there was >80% reduction in tumor size.2 Patient 5 had a synchronous, locally advanced TRK fusion positive, ER+/HER2- secretory BC and TRK fusion negative, ER+/HER2- metastatic lobular BC. Prior to TRK inhibition, this patient received 2-months of palbociclib/letrozole to which the TRK fusion negative lobular cancer responded, while the TRK fusion SBC did not. The patient tolerated the larotrectinib/letrozole combination with no notable toxicities and experienced a PR in both sites, now ongoing for 11 months.

Conclusions: We provide the first evidence that larotrectinib is effective in the treatment of BC harboring NTRK gene fusions. Assays capable of identifying NTRK gene fusions should be considered when profiling patients with BC, especially for patients with secretory BC.

Tumor epichaperome expression using $^{124}$I PU-H71 PET (PU-PET) as a biomarker of response for PU-H71 plus nab-paclitaxel in HER2 negative (HER2-) metastatic breast cancer (MBC)

Komal Jhaveri, Mark Dunphy, Rui Wang, Elizabeth Comen, Monica Fornier, Mary Ellen Moynahan, Jacqueline Bromberg, Weining Ma, Sujata Patil, Tony Taldone, Anna Rodina, Valentina Sterlin, Sareh Khoshi, Jonathan Lewis, Larry Norton, Gabriela Chiosis and Shanu Modi. 1Memorial Sloan Kettering Cancer Center, New York and 2Samus Therapeutics, 10 South Main Street Topsfield, MA.

Background: The epichaperome is a new cancer target required for tumor survival (Joshi et al. Nature Reviews Cancer 2018). PU-H71 is a synthetic, purine scaffold epichaperome inhibitor that binds to the ATP-binding site of HSP90 specifically when HSP90 is integrated into the epichaperome (Rodina et al. Nature 2016). It has demonstrated antitumor activity in multiple xenograft models. Furthermore, sequential administration of nab-paclitaxel and PU-H71 in TNBC xenograft models augmented epichaperome levels, and in turn resulted in super-synergistic drug action with ablation of xenografted tumors and cures in mice.

Methods: This is an open label phase1b study of PU-H71 + nab-paclitaxel in pts with HER2- MBC. Pts received nab-paclitaxel at a standard dose of 260mg/m$^2$ IV Q 3weeks. PU-H71 was administered IV 6 hrs (+/-1 hr) post nab-paclitaxel Q3weeks in 2 escalating dose levels (225mg/m$^2$ and 300 mg/m$^2$). All pts underwent FDG PET/CT every 6 weeks. Additionally, patients had the option to enroll on a separate diagnostic PU-PET protocol to measure epichaperome expression prior to initiating treatment on the phase 1b study, wherein they received a single dose of up to 11mci of $^{124}$I-PU-H71 IV and underwent imaging at 3-4hrs and 20-24 hrs. Primary objective was to establish the MTD/RP2D of this regimen. Secondary objectives were to assess PK of PU-H71 + nab-paclitaxel and clinical efficacy. Exploratory analysis included correlation of epichaperome expression at baseline using PU-PET with tumor response.

Results: 12 patients (5 ER+/HER2- ; 7 TNBC) were enrolled (6 at 225mg/m$^2$ of PU-H71 and 6 at 300mg/m$^2$). Median Age: 54 yrs (range: 37-71). Median lines of therapy in the metastatic setting: 6 (range 1-11) including prior taxanes in 75% of pts. Most common toxicities included diarrhea G1 58%; G2 7%, G3 7%) that was easily managed with anti-diarrheal agents, G1 fatigue (25%), G1/2 peripheral neuropathy (17%), G1 hyperglycemia (67%), G1 increases in alk phos (58%), AST (50%) and ALT (42%). Hematological toxicities included G3 leukopenia (42%), G3/4 neutropenia (67%), G3 anemia (50%) and G2 thrombocytopenia (17%). There were no DLTs. 33% (4/12) had PR, 58% (7/12) achieved SD with only 1 PD at the time of first scan; 5 pts are currently ongoing including 2 TNBC pts with PR who have been on therapy > 7 months. PK data will be presented. 8/12 patients also underwent PU-PET at baseline. A higher tumor to muscle SUV ratio at 24 hrs on PU-PET predicted response and increased PU-H71 retention on PU-PET at 24 hrs correlated with a longer duration of response.

Conclusion: The RP2D of PU-H71 was 300mg/m$^2$ with 260mg/m$^2$ of nab-paclitaxel administered IV every 3 weeks. The regimen is well tolerated with promising clinical activity in this heavily pre-treated cohort. Tumor epichaperome expression at baseline using PU-PET has the potential to serve as a predictive biomarker of response. A Phase 2 trial of this combination along with baseline PU-PET is currently planned.
Activation of AR inhibits growth of endocrine-resistant breast cancer

Kee Ming Chia1,2, Heloisa Milioli1,2, Neil Portman1,2, Geraldine Laven-Law3, Aliza Yong1,2, Alexander Swarbrick1,2, Liz Caldon1,2, Wayne Tilley3, Theresa Hickey3 and Elgene Lim1,2. 1Garvan Institute of Medical Research, Sydney, NSW, Australia; 2St Vincent's Clinical School, Faculty of Medicine, UNSW Sydney, Sydney, NSW, Australia and 3Dame Roma Mitchell Cancer Research Laboratories, Adelaide Medical School, University of Adelaide, Adelaide, SA, Australia.

Introduction
Resistance to endocrine therapy is a major clinical problem in estrogen receptor positive (ER+) breast cancer. The androgen receptor (AR) is expressed in ~90% of all ER+ breast cancers and high expression of AR is associated with a better patient outcome in this subtype. In agreement, AR activation in breast cancer cell line models reduces proliferation of cells via antagonism of ER signaling. However, uncertainty surrounding the role of AR in endocrine resistance is reflected in current clinical trials in which both AR agonists and antagonists are being investigated. In this study, we sought to investigate the optimal approach in targeting AR in endocrine-resistant breast cancer.

Methods
We evaluated the consequences of AR activation, using AR cognate ligand 5α-dihydrotestosterone (DHT) and selective AR modulator enobosarm, and AR antagonism using enzalutamide on in vitro and in vivo models of endocrine-resistance. The efficacy of these AR modulators were assessed in vitro using tamoxifen-resistant (TamR) and long-term estrogen derived (LTED) models of MCF7 cells, and in vivo using ESR1 mutant E2-dependent (HCI-005) and ESR1 wild-type E2-independent (Gar15-13) endocrine-resistant PDX models

Results
Treatment with DHT and enobosarm inhibited the growth of MCF7 TamR and LTED cells but enzalutamide had no effect. AR activation was associated with loss of ER in MCF7 TamR cells and loss of ER-regulated PR expression in MCF7 LTED which suggests that this growth suppression was mediated through the antagonism of ER signaling. Notably, an additive anti-proliferative effect was observed with the combination of enobosarm and CDK4/6 inhibitor palbociclib in the MCF7 TamR cells. A similar pattern was observed in vivo with DHT strongly inhibiting the proliferation of both PDX models. Enobosarm similarly suppressed the proliferation of HCI-005, and to a lesser extent in Gar15-13. The benefit of enobosarm in Gar15-13 was significant given that this model is fulvestrant-resistant. Antagonizing AR with enzalutamide had no effect on growth of Gar15-13 model, similar to our in vitro data. AR agonists reduced expression levels of ER and PR in HCI-005, and transcriptomic analysis of AR agonist-treated Gar15-13 identified significant negative enrichment of genes related to proliferation and estrogen response. These observations indicate that the growth-suppressive effects of AR activation in vivo were mediated through inhibiting ER signaling. We identified an AR gene signature, through RNA-seq analysis of DHT-treated Gar15-13 PDX, which is strongly associated with good outcome in the METABRIC dataset, supporting the hypothesis that an active canonical AR signaling is tumor suppressive in both endocrine-sensitive and -resistant disease contexts. Lastly, we present in vivo data demonstrating enhanced suppression of Ki-67 with the combination of enobosarm and palbociclib in the Gar15-13 PDX.

Conclusion
We have demonstrated that activating AR is an effective therapeutic approach in endocrine-resistant breast cancer, and the combination of an AR agonist with a CDK4/6 inhibitor warrants further investigation in this breast cancer subtype.
Therapeutic targeting of \( BRCA1 \) and \( TP53 \) mutant breast cancer through mutant p53 reactivation

Bing Na\(^1,2\), Xin Yu\(^1,2\), Tracy Wither\(^2\), John Gilleran\(^3\), Ming Yao\(^3\), Tzeh Keong Foo\(^5\), Chunxia Chen\(^3\), Dirk Moore\(^5\), Bing Xia\(^5\), Yong Lin\(^5\), David Kimbali\(^6\), Shridar Ganesan\(^2,3\) and Darren Carpizo\(^1,2,3\). \(^1\)Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; \(^2\)Rutgers Cancer Institute of New Jersey, New Brunswick, NJ and \(^3\)Rutgers University, Piscataway, NJ.

Triple negative breast cancer (TNBC) is an aggressive subset for which novel therapeutic approaches are needed. A significant proportion of TNBC patients harbor either germline or somatic mutations in \( BRCA1 \), or epigenetic silencing of \( BRCA1 \), which renders them deficient in DNA repair. Virtually all \( BRCA1 \) deficient breast cancers harbor mutations in \( TP53 \) suggesting that inactivation of p53 is a requirement for tumor progression in the setting of \( BRCA1 \) deficiency. Due to this dependency, we hypothesized that restoring wild type p53 function in \( BRCA1 \) deficient breast cancer would be therapeutic. The majority of \( TP53 \) mutations are missense, which generate a defective protein that potentially can be targeted with small molecules. Zinc Metallochaperones (ZMCs) are a new class of anti-cancer drugs that reactivate a class of zinc deficient mutant \( TP53 \) alleles by restoring zinc binding. Using ZMC1 in human breast cancer cell lines expressing the zinc deficient p53\(^{R175H}\), we demonstrate that loss of BRCA1 sensitizes cells to mutant p53 reactivation. Using genetically engineered murine mammary tumor models with \( Brca1 \) deficiency, we demonstrate that ZMC1 significantly improves survival in mice bearing tumors harboring the zinc deficient \( Trp53^{R172H} \) allele but not the \( Trp53 \) null allele. We synthesized a novel formulation of ZMC1 (Zn-1), in which the drug is made in complex with zinc to improve zinc delivery, and demonstrate that Zn-1 has increased efficacy over ZMC1. Furthermore, we show that ZMC1 plus olaparib is a highly effective combination for tumors expressing the p53\(^{R172H} \) mutant. In conclusion, we have validated preclinically a novel therapeutic approach for \( BRCA1 \) deficient breast cancer through reactivation of mutant p53.
Efficacy and safety of CB-839, a small molecule inhibitor of glutaminase, in combination with paclitaxel in patients with advanced triple negative breast cancer (TNBC): Initial findings from a multicenter, open-label phase 2 study

Gregory Vidal¹, Kevin Kalinsky², Erica Stringer-Reasor³, Filipa Lynce⁴, John Cole⁵, Frances Valdes-Albini⁶, Hatem Soliman⁷, Petros Nikolianakos⁸, Andrea Silber⁹, Angela DeMichele¹⁰, Haythem Alle¹¹, Deena Graham¹², Jeffrey Giguere¹³, Adam Brufsky¹⁴, Yu Liang¹⁵, Sacha Holland¹⁵, Gayle Fijif¹⁵, Bridget O’Keeffe¹⁶ and Keerthi Gogineni¹⁶.¹ West Cancer Center, Germantown, TN; ²Columbia University, New York, NY; ³UAB Comprehensive Cancer Center, Birmingham, AB; ⁴Georgetown University, Lombardi Comprehensive Cancer Center, Washington, DC; ⁵Ochsner Clinic Foundation, New Orleans, LA; ⁶University of Miami, Miami, FL; ⁷Moffitt Cancer Center and Research Institute, Tampa, FL; ⁸University Cancer and Blood Center, Athens, GA; ⁹Yale Cancer Genetics and Genomics Program, Yale Cancer Center, New Haven, CT; ¹⁰University of Pennsylvania, Philadelphia, PA; ¹¹Henry Ford Hospital, Detroit, MI; ¹²Hackensack University Medical Center, Hackensack, NJ; ¹³Greenville Health System, GHS Cancer Institute, Greenville, SC; ¹⁴Magee Women's Hospital--UPMC, Pittsburgh, PA; ¹⁵Calithera Biosciences Inc., South San Francisco, CA and ¹⁶Winship Cancer Institute of Emory University, Atlanta, GA.

Background: CB-839 is an investigational first-in-class, potent, oral inhibitor of glutaminase (GLS), a mitochondrial enzyme that controls a critical step in tumor cell utilization of glutamine. TNBC is associated with high GLS expression and depends on GLS conversion of glutamine to glutamate for tumor cell survival and proliferation. Higher glutamine utilization has been observed in TNBC tumors from patients (pts) of African ancestry (AA), compared to those of European ancestry. CB-839 has demonstrated preclinical antitumor activity in both in vitro and in vivo models of TNBC and synergizes with paclitaxel (Pac) by reversing GLS-dependent mechanisms that lead to taxane resistance. In a phase 1 study, the Pac+CB-839 combination was well tolerated and demonstrated clinical activity in a cohort of heavily pretreated pts with TNBC (22% overall response rate [ORR]; 59% disease control rate [DCR] at ≥600 mg BID dose [n=37]), including those with taxane-refractory disease or of AA (Kalinsky et al. SABCS 2017). Here we present initial findings from an ongoing phase 2 study of Pac+CB-839 in pts with advanced TNBC (NCT03057600).

Methods: Key eligibility criteria included advanced/metastatic TNBC with ECOG PS 0-1 and either 0 (1L) or ≥2 prior lines (3L+) of therapy for metastatic disease were eligible (N=112 pts max). Prior taxane therapy for the 3L+ cohorts was required. For the 1L cohorts, prior neo/adjuvant therapy (including taxanes) was allowed if time to recurrence was >12 months (mo). Pts were allocated to cohorts by line of therapy (1L or 3L+) and ancestry (AA or non-AA) in order to ensure sufficient enrollment to each of these subgroups. Pts received oral CB-839 (800 mg BID) in combination with intravenous Pac (80 mg/m² on days 1, 8, 15 of each 28-day cycle). The primary endpoint was ORR. Other endpoints included overall survival, duration of response, clinical benefit rate, biomarker analyses, and safety.

Results: As of the June 15, 2018 data cutoff, 44 pts have been enrolled (median age, 59 yrs; 41% AA; n=22 each in 1L or 3L+). In the 1L cohort, 64% and 36% had ECOG PS of 0 and 1, respectively. In the 3L+ cohort, 36% and 55% had ECOG PS of 0 and 1, respectively (9% unknown). Of 14 evaluable 1L pts, ORR was 43% and DCR (partial response [PR] + stable disease ≥8 weeks [SD]) was 79% (n=6 PR; n=5 SD). Of 16 evaluable 3L+ pts, ORR was 6% and DCR was 25% (n=1 PR; n=3 SD). Most common CB-839- or Pac-related treatment-emergent adverse events (TEAE) occurring in >15% included fatigue (34%), diarrhea (23%), nausea (18%), neuropathy (18%), alopecia (16%), anemia (16%), AST increased (16%), and hypophosphatemia (16%). Treatment-related grade ≥3 TEAEs occurred in 8 (18%) pts; the most common (occurring in >1 pt) were hypophosphatemia and neutrophil count decreased (n=2 each). No events of febrile neutropenia were reported.

Conclusions: Early analyses of this phase 2 study show that Pac+CB-839 has clinical activity and is well tolerated in pts with advanced/metastatic TNBC. Updated data including exploratory biomarker analysis will be presented.
Anti-tumor activity of elacestrant (RAD1901) in models harboring ESR1 mutations resistant to standard of care therapies

Hitisha Patel1, Nianjun Tao1, Heike Arlt1 and Teeru Bihani1. 1Radius Health, Inc, Waltham.

Background: Estrogen receptor positive (ER+) breast cancers make up approximately 75% of all breast cancers diagnosed and ER, a protein encoded by the ESR1 gene, plays a major role in the initiation, growth and survival of these cancers. Current targeted therapies inhibit the ER pathway by either blocking the synthesis of the natural ligand of ER, estradiol, (aromatase inhibitors (AI)), or by antagonizing and/or degrading the receptor (selective estrogen receptor modulators (SERMs) and selective estrogen receptor degraders (SERDs)). AIs are used in both the adjuvant and metastatic setting and recent clinical reports have shown that 20-50% of patients that had received AI therapy had detectable mutations in the ER ligand binding domain (ER-LBD). Two frequently found point mutations in the ER-LBD, Y537S and D538G, have been shown to result in estradiol-independence and constitutive activation of ER, consistent with their ability to cause resistance to AIs. While the selection of ESR1 mutations post-AI has been demonstrated clinically, the clinical response of ESR1 mutant tumors to fulvestrant, an approved SERD, is not fully understood. Preclinical studies have suggested that ESR1 mutations can cause decreased binding and a corresponding decrease in potency of ER antagonists, including fulvestrant (SERD) and tamoxifen (SERM). Conversely, clinical data from the SoFEA, PALOMA-3, and FERGI trials suggested the presence of ESR1 mutations did not alter fulvestrant activity. The limited clinical data that exists, however, is based on retrospective study designs with relatively small data sets, making it difficult to accurately predict fulvestrant activity against specific mutations and the activity of fulvestrant against tumors that harbor multiple mutations. In fact, recent additional data from the PALOMA-3 trial suggests that the Y537S mutation, specifically, was selected out in clinical samples from patients treated with fulvestrant, more closely matching preclinical results. This suggests there may be certain contexts of ESR1 mutations where fulvestrant may have limited activity. It will be important to further understand the consequence of specific mutations and to utilize therapies that have activity against all ESR1 mutations. We have previously described elacestrant (RAD1901), a novel orally bioavailable SERD, that exhibited activity in multiple ER+ breast cancer models. Interestingly, elacestrant exhibited similar effects to fulvestrant in in vitro ESR1 mutant models, however, in some in vivo PDX models harboring the Y537S mutation elacestrant inhibited growth, while fulvestrant had limited activity. Here, we describe a more complete in vivo dataset describing elacestrant activity versus fulvestrant in multiple patient-derived xenograft (PDX) models harboring ESR1 mutations.

Methods: Multiple PDX models harboring natural mutations in ESR1 or genetically-engineered CRISPR models were used to assess the anti-tumor efficacy and the pharmacokinetic/pharmacodynamic properties of elacestrant and fulvestrant.

Results: Elacestrant significantly inhibited the growth of xenograft models harboring ESR1 mutations, including those harboring Y537S or D538G mutations and models that were insensitive to fulvestrant and tamoxifen.
Pharmacological inhibition of TFF3 enhances chemo-sensitivity and overcomes acquired resistance in breast cancer

Han Ming Poh\textsuperscript{1,2}, Qing Yun Chong\textsuperscript{1}, Ru Mei Chen\textsuperscript{1,2}, Vijay Pandey\textsuperscript{3}, Basappa Salundi\textsuperscript{4}, Alan Prem Kumar\textsuperscript{1,2,5,6}, Soo Chin Lee\textsuperscript{1,5} and Peter Edward Lobie\textsuperscript{3,5}. \textsuperscript{1}Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore; \textsuperscript{2}Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; \textsuperscript{3}Tsinghua Berkeley Shenzhen Institute, Tsinghua University Graduate School at Shenzhen, Shenzhen, China; \textsuperscript{4}Laboratory of Chemical Biology, Bangalore University, Central College Campus, Bangalore, India; \textsuperscript{5}National University Cancer Institute, Singapore, Singapore and \textsuperscript{6}Cancer Program, Medical Science Cluster, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore.

Background
Dose-dependent toxicity and acquired chemo-resistance are two major challenges in the use of doxorubicin in breast cancer treatment. Trefoil factor 3 (TFF3) is a secreted ligand that promotes breast cancer progression and predicts poor survival outcome of breast cancer patients. It has also been shown to confer resistance to anti-estrogens and trastuzumab in breast cancer. Here, the role of TFF3 in regulating the sensitivity and acquired resistance to doxorubicin in breast cancer was investigated.

Methods
MCF7, ZR-75-1 and BT474 breast cancer cell lines with siRNA-mediated depletion of TFF3, and doxorubicin-resistant MCF7 cells generated from the pulsatile exposure to doxorubicin, were used as \textit{in vitro} models. We have developed a novel non-toxic small molecule inhibitor of TFF3 (AMPC) that binds specifically to cysteine 57 residue of dimeric TFF3 and promotes its dissociation to monomers thereby, inhibiting its dimeric functions such as proliferation and apoptosis. Here, the effects of AMPC in enhancing doxorubicin sensitivity and overcoming acquired doxorubicin resistance in breast cancer cells were also explored.

Results
Consistent with siRNA-mediated depletion of TFF3, pharmacological inhibition of TFF3 by AMPC enhanced doxorubicin-mediated decrease in cell viability, foci formation and 3D growth of the breast cancer cells, suggesting that TFF3 inhibition increased the sensitivity of these cells to doxorubicin treatment. Notably, AMPC combined with doxorubicin in a synergistic manner, enabling doxorubicin dose reduction for the same inhibitory effect. Doxorubicin-induced AKT activation has been reported to antagonize the effects of doxorubicin and promote its resistance in breast cancer. Here, the inhibition of TFF3 by AMPC was shown to reduce AKT activation. Mechanistically, AMPC co-treatment suppressed doxorubicin-induced AKT activation thereby enhancing doxorubicin-induced apoptosis, with an overall up-regulation of pro-apoptotic and down-regulation of anti-apoptotic proteins, as compared to doxorubicin monotherapy. TFF3 also mediated the acquired doxorubicin resistance in MCF7 cells. Elevated expression of TFF3 was observed in the doxorubicin-resistant MCF7 cells as compared to the parental MCF7 cells, while the inhibition of TFF3 by AMPC completely abrogated the resistant phenotype of these cells as shown in the cell viability, foci formation and 3D growth assays. In concordance with the elevated levels of TFF3, doxorubicin-resistant MCF7 cells also exhibited increased activation of AKT with reduced susceptibility to doxorubicin-induced apoptosis as compared to the parental MCF7 cells. Consistently, this was reversed with AMPC co-treatment, which suppressed the elevated levels of activated AKT in the doxorubicin-resistant MCF7 cells, resulting in the re-sensitization of these resistant cells to doxorubicin-induced apoptosis. Similar to that in the parental cells, AMPC also exhibited a synergistic inhibitory effect with doxorubicin in the doxorubicin-resistant MCF7 cells.

Conclusion
The pharmacological inhibition of TFF3 with AMPC is a potential therapeutic approach to reduce the dose-dependent toxicity and to overcome the acquired resistance of doxorubicin in breast cancer.
Role of GPR110 in breast cancer

Raksha Bhat¹, Lanfang Qin², Carmine De Angelis², Debashish Sahay¹, Dharmendra Bhargava¹, Chad Creighton², Puja Yadav¹, Sahar Yazdanfard¹, Ahmed Alrawi¹, Vikas Yadav¹, Suhas Vasaika², Sarmistha Nanda², Vidyalakshmi Sethunath², Xiaoyong Fu², Bing Zhang², Vihang Narkar³, Rachel Schiff² and Meghana Trivedi¹,². ¹University of Houston College of Pharmacy, Houston; ²Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston and ³University of Texas MCGovern Medical School, Houston.

Our long-term goal is to discover adhesion GPCR targets in breast cancer. Our previous studies have found GPR110 to be overexpressed in tumorigenic cell population as well as in anti-HER2 drug-resistant derivatives of HER2+ breast cancer cells. In subsequent studies, we found that GPR110 knockdown inhibited anchorage-independent cell growth, mammosphere formation, and invasion/migration of HER2+ breast cancer cells. Conversely, overexpression of GPR110 by lentiviral delivery of cDNA enhanced anchorage-independent cell growth, mammosphere formation, and invasion/migration in HER2+ breast cancer cells. In addition, GPR110 overexpression led to increase in the % of Aldefluor-positive tumorigenic cell population, further emphasizing the role of GPR110 as a mediator of tumorigenesis in addition to the metastatic processes in HER2+ breast cancer. Among various subtypes of breast cancer, GPR110 expression was higher in HER2+ and basal subtypes, most of which are triple-negative (negative for ER, PR, and HER2), compared to luminal A and B subtypes. GPR110 was either gene amplified or upregulated in 4% of all breast cancers based on the publicly available TCGA dataset. GPR110 overexpression predicted poorer recurrence-free survival in triple-negative breast cancer. Furthermore, GPR110 was overexpressed in brain metastatic lesions compared to mammary tumors in patient-derived xenograft models of triple-negative breast cancer (WHIM2 and WHIM30). Knocking down GPR110 reduced anchorage-dependent and -independent cell growth, mammosphere formation, and invasion/migration of triple-negative breast cancer cells. Overall, our results suggest that GPR110 may be a potential drug target in HER2+ and triple-negative breast cancer. Drug discovery efforts to identify GPR110 antagonists will provide useful pharmacological tools for validating GPR110 as a drug target in breast cancer. Since GPR110 is also overexpressed in various other types of cancer, understanding the mechanism of GPR110 upregulation and signaling in cancer is an important future direction.

The stapled peptide ALRN-6924, a dual inhibitor of MDMX and MDM2, enhances antitumor efficacy of paclitaxel and Nab-paclitaxel in TP53 wild-type MCF-7 breast cancer models

Seyed S Pairawan¹, Erkan Yuca¹, Kurt Evans¹, Allen Annis², Narayana Narasimhan², David Sutton², Luis A Carvajal², Jian-Guo Ren², Solimar Santiago², Vincent Guerlavais², Argun Akcakanat¹, Coya Tapia¹, Ecaterina E Illeana Dumbrava¹, Manuel Aivado² and Funda Meric-Bernstam¹.

¹The University of Texas MD Anderson Cancer Center, Houston, TX and ²Aileron Therapeutics, Cambridge, MA.

Background: MDMX and MDM2 are endogenous inhibitors of the p53 tumor suppressor protein. MDMX levels are frequently elevated in luminal breast cancer, which generally expresses wild-type p53. ALRN-6924, an α-helical stapled peptide, is the first and only dual inhibitor of MDMX and MDM2 currently in clinical trials for solid tumors and hematological malignancies. We sought to determine the antitumor efficacy of the combination of ALRN-6924 with taxanes in models of human breast cancer.

Methods: Sulforhodamine B colorimetric assay was used to assess the cytotoxicity of the combination of ALRN-6924 with taxanes in vitro. Athymic nude mice were implanted with MCF-7 tumors and treated for four weeks with ALRN-6924 alone and in combination with paclitaxel in cremaphor (Taxol®, study #1) or a nanoparticle-albumin-bound (nab) formulation (Abraxane®, study #2). In study #1, ALRN-6924 (5, 10 mg/kg) was dosed twice weekly and paclitaxel (10, 15 mg/kg) was dosed weekly, with paclitaxel administered 6 h prior to ALRN-6924. In study #2, ALRN-6924 alone (5 mg/kg) was dosed twice weekly while nab-paclitaxel (15 mg/kg) was administered weekly in combination at -24h, -6h, 0h, +6h, or +24h relative to ALRN-6924 administration.

Results: ALRN-6924 was found to have synergistic activity with paclitaxel in both MCF-7 and ZR-75-1 cell lines in vitro (Combination index: 0.874 and 0.323 respectively). In in vivo study #1, the combination of ALRN-6924 and paclitaxel significantly inhibited MCF-7 tumor growth compared to either agent alone (p≤0.005). Paclitaxel 15 mg/kg + ALRN-6924 5 mg/kg resulted in the greatest tumor inhibition with average tumor size decreased by 13% at four weeks versus the starting size.

In study #2, the combination of nab-paclitaxel with ALRN-6924 administered -6h to +24h relative to nab-paclitaxel resulted in improved efficacy over either single agent and a significant increase in the number of tumor regressions (up to 6/10 with 3 consecutive measurements <50% of starting volume) compared to nab-paclitaxel alone (1/10, p<0.005). When ALRN-6924 was administered 24h prior to nab-paclitaxel, there was a marked decrease in efficacy and no tumor regressions were observed. In both studies, drug treatments were well tolerated with no significant weight loss in mice.

Conclusion: The significant increase in efficacy observed with ALRN-6924 in combination with paclitaxel supports further evaluation in patients with breast cancer.
FGFR1β is a driver isoform of FGFR1 alternative splicing in breast cancer cells

Ming Zhao¹, Ming-Lei Zhuo², Xiaofeng Zheng¹, Xiaoping Su¹ and Funda Meric-Bernstam¹. ¹The University of Texas MD Anderson Cancer Center, Houston, TX and ²Peking University, Beijing, China.

Background: Abnormal FGFR1 alternative splicing is correlated with tumorigenicity and poor prognosis in several tumor types. We sought to determine the roles of FGFR1α and FGFR1β variants in breast cancer. Methods: TCGA breast cancer samples and cell lines were analyzed for FGFR1α and FGFR1β expression. MCF-10A cells were used to overexpress these variants. Cell growth was assessed by SRB and colony formation assays. Cell transformation was assessed by 3D-Matrigel, soft agar, cell motility assays. Cell survival assay was used to determine drug IC50. Results: In the TCGA, compared to FGFR1 non-amplified samples, FGFR1-amplified samples had significantly higher FGFR1α, but not FGFR1β levels. FGFR1β expression levels and FGFR1β/FGFR1α ratio were higher in basal subtype samples than in luminal samples in both the TCGA and in a panel of breast cancer cell lines. Both FGFR1α and FGFR1β induced transformation of MCF-10A cells. However, only FGFR1β-expressing cells, not FGFR1α, enhanced cell growth, cell motility, and FGFR signaling. Cells with higher FGFR1β levels and FGFR1β/FGFR1α ratio were more sensitive to FGFR inhibitor BGJ-398. Interestingly, in ER-negative cells, BGJ-398 decreased FGFR1β levels, likely by increasing expression of splicing repressor PTBP1. In ER-positive cells, estrogen treatment increased FGFR1β levels by decreasing PTBP1 expression, which was blocked by 4-OHT. Lastly, combination treatment with BGJ-398 and 4-OHT synergistically inhibited cell survival. Conclusions: These findings suggest that FGFR1 alternative splicing plays an important role in breast cancer, where FGFR1β functions as a driver isoform. Further work is needed to assess FGFR1β prognostic and predictive role.
The pure progesterone receptor (PR) antagonist onapristone enhances the anti-proliferative effects of CDK4/6 inhibitors in preclinical in-vitro breast cancer models

Deepak Lala¹, Tas Haque¹, Hannah Feinman², Jianghong Wu², Yuren Wang², Amy Dwyer³, Thu Truong³ and Carol Lange³.
¹Context Therapeutics, Philadelphia, PA; ²Reaction Biology Corporation, Malvern, PA and ³University of Minnesota Masonic Cancer Center, Minneapolis, MN.

Breast cancer is the most commonly diagnosed cancer and the second leading cause of cancer related death in women. Around 5–10% of cases are metastatic at diagnosis, and close to 30% of patients with early stage disease will relapse with metastatic disease. Anti-estrogen therapy is an important treatment modality for hormone receptor-positive (HR+) metastatic breast cancer (mBCa) as mono- or combination (e.g. with CDK4/6 inhibitors) first-line (1L) therapy. Unfortunately, despite the high rate of clinical benefit in 1L therapy, disease progression still generally occurs and there remains a need for an efficacious 2L therapy. Although anti-estrogens continue to play a role in 2L treatment there is a critical need for targeting additional mechanisms in combination with anti-estrogens. Progesterone is a major mitogen in the adult human mammary epithelium and, in addition to ER, is a key driver of breast cancer cell proliferation. Thus, blocking both ER and PR would likely be an effective approach for inhibition of all hormone driven breast cancer cell proliferation. Onapristone is a unique PR full antagonist that is efficacious as an antitumor agent in multiple preclinical breast cancer models and exhibits additive/synergistic effects with antiestrogens. Here, we examine the effects of onapristone in in-vitro model systems in combination with CDK4/6 inhibitors.

Methods: T47D cells were treated with various concentrations of onapristone or palbociclib in media containing 10%FBS.10 days after treatment cell viability was determined using Cell Titer Glo. Cells were also treated with increasing concentrations of palbociclib in the absence or presence of onapristone and analysed for cell proliferation after 10 days and for gene expression after 3 days of treatment. The effects of onapristone were also tested in soft agar anchorage-independent growth assays as well as 3D tumorsphere assays using ER+/PR+ MCF7 and BT474 cells +/- onapristone for 21-28 days. Formed colonies or spheres were analyzed morphologically using cell stain and by quantifying the total number and size of colonies or spheres formed.

Results: Onapristone inhibited T47D cell proliferation in a concentration-dependent manner. Additionally, it sensitized the cells to inhibition by CDK4/6 inhibitors in the preclinical in-vitro models. Onapristone also had a marked effect on downstream target genes in the cell-based models providing a mechanistic basis for the anti-proliferative effects. Onapristone also blocked progesterone-induced breast cancer cell survival in either soft agar or 3D tumorsphere assays with effects comparable to that of anti-estrogen (fulvestrant).

Conclusions: Onapristone inhibits T47D proliferation and key target genes involved in cell proliferation. Additionally, onapristone enhances the anti-proliferative effects of palbociclib in-vitro. Previous studies have provided a clear rationale for combining onapristone and anti-estrogens in the clinic for the treatment of breast cancer. Our data extend these studies to provide additional rationale for the combination of onapristone with CDK4/6 inhibitors such as palbociclib as an effective new approach for the treatment of breast cancer.
Neutralizing soluble tumor necrosis factor alpha overcomes trastuzumab-resistant breast cancer immune evasion by downregulating mucin 4, improving NK cell function and decreasing myeloid-derived suppressor cells in tumor microenvironment

Roxana Schillaci¹, Sofia Bruni¹, Mara De Martino¹, María F Mercogliano¹, Gloria Inurrigarro², Isabel Frahm², Cecilia J Proietti¹ and Patricia V Elizalde¹. ¹Instituto de Biología y Medicina Experimental, Buenos Aires, Argentina and ²Sanatorio Mater Dei, Buenos Aires, Argentina.

**Background:** Novel strategies aimed to overcome trastuzumab (Tz) resistance of HER2+ breast cancer (BC) are needed. Recently, we demonstrated a novel immune evasion strategy used by BC where tumor necrosis factor alpha (TNF) induces upregulation of the transmembrane glycoprotein mucin 4 (MUC4) via NF-kB activation to impair Tz binding that prevents antibody mediated killing of BC cells. Etanercept, a non-selective inhibitor of soluble and transmembrane TNF (sTNF, tmTNF), downregulated MUC4 expression and sensitized de novo Tz-resistant BC xenografts to Tz. Moreover, we showed that MUC4 expression is an independent predictor of poor disease-free survival in patients treated with Tz in the adjuvant setting (Clin Cancer Res 2017, 23:636). Etanercept is immunosuppressive due to off-target effects on tmTNF while selective inhibition of sTNF improves the immune response to the tumor (Cancer Immunol Res 2016, 4:441). Because of the immunosuppressive properties of etanercept, we wanted study if the dominant negative-TNF protein XPro1595 (DN-TNF; also known as INB03) that neutralizes sTNF without affecting tmTNF is able to downregulate MUC4 to inhibit Tz-resistant tumor growth and improve innate antitumor immune response.

**Methods:** To assess the effect of DN-TNF on Tz-resistant HER2+ tumor growth, JIMT-1 cells were s.c. injected in nude mice. When tumors were established, animals were treated with IgG, DN-TNF, Tz or DN-TNF+Tz, i.p. twice a week for one month. Innate immune response was determined by flow cytometry analysis of NK cells activation and degranulation and myeloid-derived suppressor cells (MDSC) subtypes in tumor microenvironment (TME) and in spleen. Tz-dependent NK cells degranulation was assessed in splenocytes using HER2+, Tz-sensitive cell line BT-474 as the target. MUC4 and phospho NF-kB expression was determined by Western blot.

**Results:** Treatment with Tz or DN-TNF had no impact on JIMT-1 tumor growth. However, co-treatment with DN-TNF and Tz resulted in significantly less growth. At day 21st, tumor volume was 75mm³ in DN-TNF+Tz vs 300mm³ control groups. DN-TNF+Tz treatment showed a decrease in myeloid cell infiltration and MDSC phenotype was enriched in the granulocytic-MDSC vs monocytic-MDSC suggesting a less immunosuppressive TME. DN-TNF+Tz administration significantly increased activation and degranulation of tumor infiltrating NK cells. In addition, spleen NK cells from these animals exhibited enhanced Tz-dependent degranulation vs control groups. MUC4 expression was downregulated in tumors treated with DN-TNF and NF-kB phosphorylation was inhibited (all comparisons p<0.05).

**Conclusion:** These results suggest that targeting sTNF together with Tz treatment improves antitumor immune response reducing tumor burden. Activated NK cells can more effectively attack the tumor due to a less suppressive TME and decreased MUC4 expression enhancing Tz binding in Tz-resistant HER2+ BC. Patients with increased levels of TNF expressing MUC4 in their tumors could be eligible for a combined therapy with DN-TNF and Tz to overcome/avoid resistance to therapy. These results can be translated quickly into the clinic.
Characterization of a novel prognostic and targetable modulator of the Wnt/β-catenin signaling pathway in breast cancers

Nawat Bunnag1,2, Yi Yuan2,3, Wanpei Cai2, Jahnavi Suresh1, Lee Young Bok4, Kim Deog Joong4, Nicholas Tolwinski1,5 and Alan Prem Kumar2,3. 1Yale-NUS College, Singapore, Singapore; 2Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore; 3Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; 4Rexahn Pharmaceuticals, Inc, Rockville, MD and 5National University of Singapore, Singapore, Singapore.

Mortality in metastatic triple negative breast cancer (TNBC) remains high due to a lack of targeted therapy options. Consequently, there is a pressing need to identify prognostic markers and therapeutic targets for TNBC. Our group identified the DEAD-box RNA helicase DP103 as a novel prognostic biomarker and metastasis-driving oncogene enriched in TNBC. Aberrant Wnt/β-catenin signaling has been implicated for driving growth and metastasis of many cancers, like TNBC. Our studies found that the depletion of DP103 in metastatic TNBC cells resulted in decreased Wnt activity and expression of downstream Wnt target genes such as Axin2 and c-Myc. In addition, stimulation of the Wnt pathway via GSK3β inhibition or Wnt-3a recombinant protein significantly increased the transcriptional expression of DP103, indicating a possible positive feedback loop. To validate this new role for DP103 in regulating the Wnt/β-catenin signaling pathway in vivo, we developed a novel Drosophila stem cell and tumor model by generating a genetic mosaic of oncogenic Ras and β-catenin in Drosophila. The co-expression of these oncogenes caused benign tumor formation in Drosophila larval tissue that were visualized and used to identify key genetic modifiers necessary for growth and invasion into neighboring tissues. RX-5902, a novel Wnt/β-catenin modulator preventing the nuclear translocation of β-catenin via phosphorylated p68 decreased the transcriptional expression of DP103 and inhibited tumor formation as observed in our Drosophila model. Interestingly, overexpression of DP103 abrogated the effects of RX-5902, suggesting a requirement for RX-5902-mediated downregulation of DP103 to bring about anti-tumorigenic effects. Collectively, our data suggests a novel regulatory role for DP103 in the Wnt/β-catenin signaling pathway that is targetable by drugs like RX-5902.
BAT8003, a potent anti-Trop-2 antibody-drug conjugate, for the treatment of triple negative breast cancer

Weijia Tang, Xiaoyang Huang, Ziqiang Ou, Hui Yan, Jirong Gan, Qingfeng Dong, Binghua Tan, Yili Yang, Yanling Guo, Shengfeng Li, Bert Thomas and Jin-Chen Yu. 1Bio-Thera Solutions, Ltd., Guangzhou, Guangdong, China.

Trophoblast cell surface antigen 2 (Trop-2) is overexpressed on many epithelial carcinomas, yet is expressed at much lower level on normal tissue. Overexpression of Trop-2 has been correlated with poor prognosis in several solid tumors. These two characteristics make Trop-2 a potential drug target. An antibody-drug conjugate (ADC) targeting Trop-2, IMMU-132, has recently been demonstrated to be effective in treating triple negative breast cancer (TNBC) and gastric cancer patients. Here we present a Trop-2 ADC, BAT8003, which contains an uncleavable linker and a maytansine derivative as the payload. An A114C mutation on antibody heavy chain was introduced to BAT8003 for site-specific conjugation, in order to generate a more homogeneous product for a better pharmacokinetics profile. BAT8003 is also completely devoid of fucose modification, to allow for enhanced ADCC effect. We show that BAT8003 is effectively internalized upon binding to Trop-2, and inhibits proliferation of Trop2-overexpressed tumor cells with IC50s of ~1 nM. In a TNBC (MDA-MB-468 cell) mouse xenograft model, BAT8003 strongly inhibits tumor growth at a dose level as low as 5 mg/kg. BAT8003 also demonstrates potent activity in another TNBC (MX-1 cell) mouse tumor model, in which it shows the same inhibition activity as the naked antibody conjugated heterogeneously with almost two fold payload (DAR 3.5), suggesting the effect caused by site-specific conjugation. We are currently developing BAT8003 for clinical evaluation in TNBC and other cancer indications.
Targeting SHP2 for the treatment of HER2-positive breast cancer

Yehene Agazie' and Zachary Hartman'. 1West Virginia University, Morgantown, WV.

Approximately 20% of breast cancer (BC) is caused by overexpression of the human epidermal growth factor receptor 2 (HER2). As a result, several antibody-based and small molecule-based anti-HER2 therapies have been developed. These drugs have benefited BC patients by improving overall survival and quality of life. However, development of resistance and disease recurrence have been the major clinical challenges. One way to overcome these clinical problems is to develop alternative therapeutic strategies. Multiple lines of evidence show that targeting the Src homology phosphotyrosyl phosphatase 2 (SHP2) in HER2-positive BC may prove beneficial both in treatment-naïve and anti-HER2 therapy-resistant forms of the disease. For instance, silencing SHP2 expression in HER2-positive breast cancer cells or conditional knockout in ErbB2 transgenic mice blocks HER2 overexpression and associated signaling, leading to loss of cell transformation and tumorigenesis. To test the clinical translational significance of SHP2 targeting, we have invented a specific small molecule SHP2 inhibitor named WGMDY (US 9,932,288) that has shown promising anti-cancer effects. The results obtained so far show that inhibition of SHP2 with WGMDY blocks HER2 expression, suppresses cell proliferation and anchorage independent growth, and induces regression of preformed xenograft tumors. These findings suggest that SHP2 might be an excellent drug target for HER2-positive BC and WGMDY has a promising potential to serve as a lead compound for developing anti-SHP2 drugs.
Xentuzumab (BI 836845), an insulin-like growth factor (IGF)-neutralizing antibody (Ab), combined with exemestane and everolimus in hormone receptor-positive (HR+) locally advanced/metastatic breast cancer (LA/mBC): Randomized phase 2 results

John Crown1, Marie-Paule Sablin2, Javier Cortés3,4, Jonas Bergh5, Seock-Ah Im6, Yen-Shen Lu7, Noelia Martínez3, Patrick Neven8, Keun Seok Lee9, Serafín Morales10, J Alejandro Pérez-Fidalgo11, Douglas Adamson12, Anthoney Goncalves13, Aleix Prat14, Guy Jerusalem15, Laura Schlieker16, Rosa-Maria Espadero17, Thomas Bogenrieder18, Dennis Chin-Lun Huang19 and Peter Schmid20.

KG, Staburo GmbH & Co. KG, Staburo GmbH, Munich, Germany; 17Boehringer Ingelheim España S.A., Barcelona, Spain; 18Boehringer Ingelheim RCV, Vienna, Austria; 19Boehringer Ingelheim Taiwan Limited, Taipei, Taiwan and 20Centre for Experimental Cancer Medicine, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom.

**Background:**
Xentuzumab (Xen), an IGF-1/-2-neutralizing Ab, binds IGF-1 and IGF-2, inhibits their growth-promoting signaling, and suppresses AKT activation by everolimus (Ev). This Phase 1b/2 trial evaluates Xen in combination with Ev and exemestane (Ex) in HR+/HER2− LA/mBC.

**Methods:**
The two-arm, open-label, randomized Phase 2 part enrolled female patients (pts) with HR+/HER2− LA/mBC not amenable to curative therapy and refractory to nonsteroidal aromatase inhibitors. Pts were randomized (1:1) to: oral Ev (10 mg/d) + Ex (25 mg/d); or Xen (1000 mg/wk iv) + Ev (10 mg/d) + Ex (25 mg/d). Randomization was stratified by visceral metastases (VM; Y vs N). Treatment continued in 28-day cycles until progression, intolerable adverse events (AEs) or other reasons for discontinuation. Primary endpoint was progression-free survival (PFS), with an interim futility analysis incorporated in the study design.

**Results:**
Following the results of the interim analysis, the Data Monitoring Committee (DMC) advised early termination of the trial and discontinuation of Xen treatment. Thus, Xen treatment exposure time and time-to-event data for the Xen+Ev+Ex arm are limited. Of the 139 women treated (Xen+Ev+Ex 70; Ev+Ex 69), 77% had VM. Median PFS was not significantly different between arms (Xen+Ev+Ex vs Ev+Ex, 7.3 vs 5.6 months; HR [95% CI] 0.97 [0.57–1.65]; p=0.91). In a pre-specified subgroup of pts without VM, Xen+Ev+Ex showed favorable PFS vs Ev+Ex (HR 0.21 [0.05–0.98]; Pint=0.0141). Pint values <0.05 were also observed for ad hoc subgroups: measurable disease at baseline; bone-only metastases. Rates of total AEs/grade ≥3 AEs/drug-related AEs were similar between arms (Xen+Ev+Ex, 100/60/96%; Ev+Ex, 99/58/96%). The most common AEs overall were diarrhea (44 vs 33%), mucosal inflammation (39 vs 32%), rash (34 vs 33%) and stomatitis (34 vs 38%); most were grade 1/2. 6% of pts in the Xen+Ev+Ex arm discontinued Xen due to AEs. Ev/Ex discontinuations (Xen+Ev+Ex vs Ev+Ex) occurred in 13/6% vs 23/6%; 1 pt each in the Xen+Ev+Ex arm died from pneumonitis and liver injury and 1 pt each in the Ev+Ex arm died from Burkitt's lymphoma, acute kidney injury and metastases to the peritoneum.

**Conclusion:**
In the overall population, PFS did not improve with the addition of Xen to Ev+Ex and the trial was therefore discontinued early. Nevertheless, a favorable signal was observed in the pre-specified subgroup of pts without VM when treated with Xen+Ev+Ex, which warrants additional investigation. The safety profile was comparable between arms.
Phase I trial of intratumoral (IT) administration of a NIS-expressing derivative manufactured from a genetically engineered strain of measles virus (MV)

Background: The live attenuated non-pathogenic Edmonston MV vaccine strain has advantages as an oncolytic platform given its tumor specificity, potent bystander effect, and ability to be engineered and retargeted. MV-NIS expresses the human thyroidal sodium-iodide symporter (NIS) and is selectively oncolytic, entering tumor cells through CD46 (overexpressed on many cancers, including breast cancer of all subtypes) and Nectin-4. NIS expression in MV-NIS infected cells permits noninvasive monitoring of virus spread by SPECT-CT imaging of Tc-99m pertechnetate or I-123 uptake.

Methods: NCT01846091 is a standard 3+3 phase I trial of a single IT administration of MV-NIS in pts with recurrent/metastatic squamous cell carcinoma of the head and neck (SCCHN) or metastatic breast cancer (MBC). Primary objectives are (a) safety and tolerability and (b) maximally tolerated single dose. The secondary clinical objective is to preliminarily assess antitumor efficacy at and away from the MV injection site. Key eligibility criteria were: absence of standard therapy with life prolonging intent; at least one lesion ≥1 cm amenable to percutaneous injection; and no impending visceral crisis. MV-NIS was administered on D1 with mandatory SPECT-CT at baseline (BL) and on D3&D8; repeat SPECT-CT on D15&D21 if the prior result was positive; mandatory tumor biopsies on D3&D21; optional tumor biopsies on D8&D15; assessments for viremia and viral shedding at BL and on D3,D8,D15,D21; and standard imaging for restaging at BL, D21, W6, W12.

Results: Accrual completed with 12 evaluable pts (6 SCCHN and 6 MBC) at 3 dose levels ($10^8$, $3 \times 10^8$, $10^9$ TCID$_{50}$). The MBC group included 5 HR+/HER2- pts and 1 pt with mixed HR+/HER2- and HR+/HER2+ disease. 5 pts had evidence of disease progression prior to study participation. No dose limiting toxicities were observed among the MBC pts; AEs possibly related to MV-NIS in this group were gr2 fatigue, gr1 flu-like illness, gr2 lymphopenia (all n=1). No SCCHN responses were observed. Best response for the MBC pts was: stable disease (SD) >6 wks, n=4; clinical response, n=1; progression, n=1. One MBC pt with SD for 12 wks had positive SPECT/CT imaging at and away from the injection site on D3&D8 and was the only pt seronegative for measles IgG antibodies prior to MV-NIS exposure. The MBC pt who responded after initial MV-NIS exposure was the only pt with low viral RNA in blood (D3); she received additional doses at W9&W13 without toxicity through an expanded access protocol exemption and had disease progression by W19. No viral shedding was detected from mouth rinse or urine in any pt. MV was detected in tumor samples from all pts treated at the highest dose level. Additional blood and tissue analyses are in progress.

Conclusion: These results demonstrate the safety of IT MV-NIS administration, provide early evidence of biologic activity in MBC, and support the possibility of viral replication in tumors remote from the IT injection site. A MV strain encoding the immunomodulatory neutrophil activating protein transgene has been constructed (MV-s-NAP) with preclinical evidence of improved antitumor activity and immunogenicity. The phase I MV-s-NAP trial will start recruitment in Fall 2018.
Targeting PI3Kβ alone and in combination with chemotherapy or immunotherapy in tumors with PTEN loss

Nicci Owusu-Brackett, Ming Zhao, Argun Akcakanat, Kurt W Evans, Erkan Yuca, Coya Tapia, Ecaterina Ileana-Dumbrava, Filip Janku and Funda Meric-Bernstam. The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: PTEN functions as a negative regulator of the phosphatidylinositol 3-kinase (PI3K)/AKT/mTOR pathway to promote balanced cell proliferation, survival and differentiation. PTEN loss occurs across a variety of cancer subtypes; PTEN-deficient tumors are dependent on PI3Kβ activity, making PI3Kβ a compelling target. We evaluated the efficacy of PI3Kβ inhibitor AZD8186 as a single agent and in combination with standard chemotherapy and immune checkpoint inhibitors focused on tumors with loss of PTEN function.

Methods: In vitro, cell proliferation assays were performed to determine the half maximal inhibitory concentration (IC50) after 3 days of treatment and to test the effects in combination with standard chemotherapy. Colony formation assays were performed to confirm efficacy of AZD8186 in PTEN-deficient cell lines. Western blot analysis was performed to assess PTEN protein expression and to evaluate effects of AZD8186 on PI3K signaling. In vivo, antitumor efficacy of AZD8186 as a single agent as well as in combination with paclitaxel and anti-PD1 was evaluated.

Results: AZD8186 inhibited the cell proliferation of three of ten TNBC cell lines in vitro; PTEN loss was significantly correlated with AZD8186 sensitivity (p= 0.008). Colony formation assay confirmed sensitivity of PTEN-deficient cell lines to AZD8186. AZD8186 inhibited PI3K signaling with decreased expression of pAKT, pGSK3β, pPRAS40 and pS6. AZD8186 treatment of PTEN-deficient cell lines, MDA-MB-436 and MDA-MB-468, resulted in increased apoptosis. Cell proliferation assays demonstrated additive effect of the combination of paclitaxel with AZD8186. AZD8186 significantly enhanced antitumor activity of paclitaxel in MDA-MB-436 and MDA-MB-468 cell-line-derived xenografts, with disease stabilization in the latter. In syngeneic models, AZD8186 enhanced antitumor efficacy of anti-PD1 antibodies in PTEN-deficient BP murine melanoma xenograft (p=0.0073), but not in PTEN-wildtype colon carcinoma, CT26.

Conclusion: AZD8186 has single agent efficacy in PTEN-deficient triple negative breast cancer cell lines in vitro, with modest single agent efficacy in vivo. AZD8186 enhanced the antitumor efficacy of paclitaxel and of Anti-PD1 antibodies in vivo. Further study is needed to determine optimal combination therapies for PTEN-deficient solid tumors.
Concurrent exercise and chemotherapy in preclinical breast cancer models

Sara Wahlroos¹,²,³, Ashleigh Wilkinson¹, David Gallego-Ortega¹,³, Mark Febbraio¹,³ and Elgene Lim¹,²,³.¹ The Garvan Institute of Medical Research, Sydney, NSW, Australia; ² The Kinghorn Cancer Centre, St Vincent's Hospital, Sydney, NSW, Australia and ³ St Vincent's Clinical School, Faculty of Medicine, University of New South Wales, Sydney, NSW, Australia.

The benefits of exercise following a cancer diagnosis is increasingly recognized. Increased physical activity is associated with reduced breast cancer recurrence and breast cancer specific mortality. However, the mechanisms underpinning this effect are still under investigation. The role of exercise as an adjunct to systemic therapy for breast cancer remains unclear. We hypothesize that exercise may exert an anti-tumor effect and a change in tumor immune cell infiltration.

Methods
We evaluated the effect of exercise alone and in combination with chemotherapy in preclinical patient-derived TNBC xenografts (PDX) established in Nude mice and PyMT mouse tumor models. Mice were individually housed in boxes equipped with running wheels and randomized to 1) clamped wheels (sedentary controls), 2) doxorubicin (Dox, 2mg/kg/week), 3) exercise (Ex) and 4) Ex + Dox. Daily distance run was measured. One week after randomization (acclimatization period), the intervention was commenced. Body composition was measured at randomization and at end point. Tumors were harvested after 5 weeks of intervention or at ethical endpoint. Tumor immune infiltrates were analyzed, and transcriptomic analysis performed.

Results
In the TNBC PDX model, there was no difference in tumor volume at randomization (p=0.96), or cumulative distance run after 1 week of acclimatization to the running wheel (p=0.47). At 5 weeks, Ex alone significantly reduced tumor growth rate compared with controls (relative reduction 10%, p=0.025). There was no difference between the other interventions. Mice randomized to Ex + Dox ran a shorter cumulative distance over 5 weeks compared with Ex alone (103.6 ± 16.2km vs 168.8 ±23km, p=0.028). There was no correlation between distance run and tumor volume in either of the treatment cohorts involving exercise (p=0.39). PyMT, transcriptomic and immune cell infiltration analysis will be reported.

At baseline, there was no significant difference in mean total body mass (TBM), lean mass (LM) or fat mass (FM) between the intervention groups (p>0.05). At 5 weeks, the mean TBM and LM in both groups treated with Dox was significantly lower than Ex only and controls. The Ex and the control mice gained weight (11%), compared with Dox only and Ex + Dox mice which did not gain weight (0% and -6% respectively). Therefore exercise had no significant impact on TBM or LM at 5 weeks, but Dox resulted in loss of TBM and LM compared with mice not treated with Dox.

Conclusion
Exercise significantly reduced tumor growth compared with sedentary controls in our preclinical TNBC PDX model, however there was not synergistic effect seen with Dox. Cumulative doses of Dox resulted in weight loss and loss of lean mass, and reduced the cumulative running distance, compared with mice not treated with Dox.
Target N-Ras for degradation by flunarizine to treat basal-like breast cancer

Ze-Yi Zheng¹, Jing Li¹, Fuhai Li², Yangqiao Zhu², Kemi Cui², Stephen T Wong², Eric C Chang¹ and Yi-hua Liao³. ¹Baylor College of Medicine, Houston; ²The Methodist Hospital Research Institute, Houston and ³National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan.

Background: Basal-like breast cancer (BLBC) is an aggressive form of breast cancer that are usually triple negative for ER, PR, and HER2. There is no effective targeted therapy for BLBC due to the lack of a druggable driver. Ras GTPases are powerful drivers for tumorigenesis. We have shown that wild type N-Ras, but not K- or H-Ras, is overexpressed in BLBC and driving its growth and transforming activities. However, there is currently no treatment that directly target Ras. This study thus screened existing pharmacologically active and approved compounds for the new ability to induce N-Ras degradation in BLBC.

Methods: Compounds in the LOPAC library were screened by an automated microscopy system for the ability to reduce GFP-N-Ras signals in the cells. Isolated compounds were then examined to identify those that can degrade endogenous N-Ras in BLBC cells without impacting levels of other Ras proteins. Final candidate compounds were further examined to determine by which proteolytic pathway N-Ras is induced to be degraded. The potentials of the identified compound to treat BLBC were assessed by examining cell growth and soft agar colony formation in vitro and tumor growth in vivo.

Results: We identified flunarizine (FLN), previously approved for treating migraine and epilepsy. The FLN-induced N-Ras degradation was not affected by a 26S-proteasome inhibitor. Rather, it was blocked by autophagy inhibitors. Furthermore, N-Ras can be seen co-localized with active autophagosomes upon FLN treatment, suggesting that FLN alters the autophagy pathway to degrade N-Ras. Importantly, FLN treatment recapitulated the effect of N-RAS silencing in vitro by selectively inhibiting the growth of BLBC cells, but not that of breast cancer cells of other subtypes. In addition, in vivo FLN inhibited tumor growth of a BLBC xenograft model.

Conclusion: This proof-of-principle study presents evidence that the autophagy pathway can be coerced by small molecule inhibitors, such as FLN, to degrade Ras as a strategy to treat cancer. FLN has low toxicity and should be further investigated to enrich the toolbox of cancer therapeutics against BLBC.
The stapled peptide ALRN-6924, a dual inhibitor of MDMX and MDM2, and the CDK4/6 inhibitors palbociclib or abemaciclib synergistically enhance each other's *in vitro* and *in vivo* anticancer activity

Allen Annis¹, Luis A Carvajal¹, Jian-Guo Ren¹, David Sutton¹, Solimar Santiago¹, Narayana Narasimhan¹, Vincent Guerlavais¹ and Manuel Aivado¹. ¹Aileron Therapeutics, Inc., Cambridge, MA.

**Background** ALRN-6924 is a cell-penetrating α-helical stapled peptide that disrupts the interaction of the p53 tumor suppressor protein and its inhibitors, MDMX and MDM2. Reactivation of p53 with ALRN-6924 in TP53-wild-type tumors triggers cell cycle arrest and apoptosis resulting in antitumor efficacy. CDK4/6 inhibitors induce apoptosis, senescence, and cell growth arrest via the interrelated Rb pathway, and co-amplification of MDM2 and CDK4 (both on chromosome 12q13) is a known oncogenic driver, suggesting that combinations of ALRN-6924 and CDK4/6i's may be synergistic. This study evaluates the antitumor efficacy and pharmacodynamics (PD) of ALRN-6924 combined with palbociclib or abemaciclib.

**Methods** ALRN-6924 was tested in combination with palbociclib or abemaciclib in MCF-7 breast cancer cell lines and MDM2- and CDK4-co-amplified SJSA-1 sarcoma cell lines using WST-1 cell viability assays. Synergy was quantified by the Chou-Talalay combination index method. Single agents and combinations were evaluated in cell culture using assays for apoptosis (Caspase 3/7 cleavage), proliferation (BrdU), senescence (β-Galactosidase), colony growth (Giemsa), and Western blot analysis of p53, p21, Rb, phospho-Rb, FOXM1, and phospho-FOXM1; and E2F1 mRNA. *In vivo* combinations were tested in athymic nude mouse MCF-7 and SJSA-1 xenograft models, with cell cycle assays (EdU) measured in tumor samples by flow cytometry.

**Results** ALRN-6924 combinations with palbociclib or abemaciclib display synergistic *in vitro* anti-proliferative activity in MCF-7 and SJSA-1 cells. ALRN-6924 induces senescence *in vitro* as a monotherapy and in combination with CDK4/6i's. Western blot assays show that ALRN-6924/palbociclib combinations trigger sustained on-mechanism biomarker activation, vs. transient activation with single agents. Phospho-Rb and phospho-FOXM1 down-regulation, p53 and p21 up-regulation, and repression of E2F1 mRNA are sustained after wash-out in combination, but not in single agent-treated cells. MCF-7 and SJSA-1 tumor growth inhibition was improved in mice treated with ALRN-6924 combinations with either palbociclib or abemaciclib vs. single agent. EdU assays show that ALRN-6924/palbociclib combinations inhibit SJSA-1 tumor cell proliferation *in vivo*. Body weights and mortality data show the combination of ALRN-6924 with palbociclib 75 mg/kg/day was well tolerated; the combination with abemaciclib 100 mg/kg/day was tolerated with interruption and dose-reduction. No pharmacokinetic (PK) drug-drug interactions were noted in nude mice due to different modes of metabolism for ALRN-6924 (proteolysis) and palbociclib (CYP3A).

**Conclusions** This study demonstrates that ALRN-6924 and CDK4/6i combinations show synergistic activity. PD biomarkers indicate on-mechanism *in vitro* activity that is sustained after wash-out. *In vivo* efficacy, biomarker, PK, and tolerability results, plus clinical evidence that the most frequent and concerning safety issues for CDK4/6i's (neutropenia, leukopenia, infections) do not overlap with ALRN-6924's reported safety profile (Meric-Bernstam et al., ASCO 2017) support the development of combination regimens for breast cancer and other malignancies.
Synergistic anti-cancer activity of cyclin-dependent kinase 4/6 inhibitor palbociclib and dual mTOR kinase inhibitor MLN0128 in pRb-expressing triple negative breast cancer

Takuro Yamamoto¹, Noriko Kanaya¹, George Somlo² and Shiuan Chen¹. ¹City of Hope Beckman Research Institute, Duarte, CA and ²City of Hope Medical Center, Duarte, CA.

**Background**

No targeted therapies have been approved for triple negative breast cancer (TNBC) thus far. Retinoblastoma protein (pRb), a major substrate of cyclin-dependent kinase (CDK) 4/6, might be a potential target especially in chemoresistant TNBC. Palbociclib is a first approved oral CDK4/6 inhibitor for treatment of patients with estrogen receptor (ER)-positive and human epidermal growth factor receptor 2 (HER2)-negative breast cancers. Nevertheless, the usefulness of CDK4/6 inhibitors has not been established in patients with TNBC although, pRb is expressed in approximately 60% of this subtype of breast cancer. In addition, pRb expression has been shown to be associated with poor prognosis after chemotherapy. This pre-clinical study investigated the combination effects of palbociclib with oral dual mTOR kinase inhibitor MLN0128 in TNBC in vitro and in vivo.

**Methods**

Four TNBC cell lines (MB231, MB453, MB468, and CAL148) were tested with the combination of two drugs in vitro. The combination effects on cell proliferation were investigated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay and colony formation assay. Cell cycle analysis and level changes of molecules related to G1/S transition and mTOR pathway were examined. Importantly, a pRb-expressing TNBC patient-derived xenograft (PDX) model was used for confirming the combination effect in vivo.

**Results**

Palbociclib suppressed cell proliferation in pRb-expressing cell lines (MB231 and MB453), not pRb-deficient lines (MB468 and CAL148). The combination of palbociclib with MLN0128 showed synergistic inhibition of proliferation of MB231 and MB453 cells. Western blot analysis revealed that CDK4/6-pRb and mTOR-p70S6K pathways were inhibited by palbociclib or MLN0128 alone, but considerably more effective by the combination treatment. Cell cycle analysis showed that this combination induced G1 cell cycle arrest. The combined effect of palbociclib and MLN0128 were investigated further in vivo. In pRb-expressing TNBC PDX, the combination treatment drastically inhibited pRb phosphorylation and tumor growth compared to control or single treatment. In addition, effective reduction of PDX tumors was also demonstrated by major suppression of Ki67-positive cells by the combination treatment compared to control or single treatment.

**Conclusions**

In this pre-clinical study, we discovered that the combination treatment of CDK4/6 inhibitor palbociclib and dual mTOR kinase inhibitor MLN0128 had synergistic anti-cancer activity in pRb+ TNBC cell lines and a PDX model. Our results prove that such combination therapy is earnest to be further investigated in a clinical setting.
muTarget.com: Linking gene expression and mutation status to identify patient cohorts eligible for targeted- and immunotherapy in breast cancer

Balázs Győrffy¹,² and Tibor Nagy¹. ¹MTA TTK, Budapest, Hungary and ²Semmelweis University, Budapest, Hungary.

Selection of cancer patients for new targeted therapies reached its dead end as next generation sequencing based precision oncology approaches failed to deliver breakthrough improvements to oncology practice. The problem with current approaches is that the effect of a mutation can be indirect by influencing the expression of various other genes, which in turn can act as new therapy targets. A large-scale analysis of such cascades was not yet executed in breast cancer. Here, we developed an analysis tool to identify targetable genes showing an altered expression in relation to a mutation in other genes.

The background database includes two independent large patient's cohorts, the TCGA and the Metabric datasets. Mutation status for each gene was determined using the VCF files from the TCGA repository. RNA-seq gene expression data for the same patients was re-normalized using a scaling normalization. Gene expression for the Metabric samples was determined using Illumina gene arrays and mutation status for the same patients is available for 174 selected genes. The Metabric database includes 1,981 patients and the TCGA breast cancer database contains 1,091 patients. Expression is linked with mutation status for each gene across all patients using Mann-Whitney test. A p<0.05 and a false discovery rate of <10% was accepted as significant.

We demonstrate the utility of the analysis platform by using it to uncover patient cohorts with higher expression of PD1 (PDCD1) and PD-L1 (CD274). Immune checkpoint inhibitors pembrolizumab and nivolumab target PD1. PD-L1 inhibitors include atezolizumab, avelumab, and durvalumab. None of these immunotherapy agents is approved to be used in breast cancer. In both settings, only one gene reached statistical significance. For PD1, the best performing gene was NOP14. Patients with mutation in NOP14 (1.3% of patients) had a 2.08x increased expression (4.58 in mutated vs. 2.20 in wild type) of PD1 (p=8.4e-05, FDR=0.0239). For PD-L1, the strongest gene was CCDC88A (mutated in 2.6% of patients), which had a 2.03x increased expression (10.42 in mutated vs. 5.13 in wild type) of PD-L1 (p=6.2e-05, FDR=0.0147). Both NOP14 and CCDC88A have been linked to cancer development and progression, but have not been investigated in relation to immune therapies. One can anticipate that patients with mutation in these genes will be prone to respond to immune checkpoint inhibitors.

In summary, an online portal was set up capable to identify genes with altered expression in relation to a given mutation. The presented approach can help to increase speed and reduce cost of development for future anticancer treatments. The analysis tool also enables identification of patient cohorts for new agents and is accessible at www.mutarget.com.
Talazoparib and decitabine combination therapy: When DNA damage repair process impairing can be a benefit

Romain Pacaud¹, Scott Thomas¹, Elysia Roche¹, Nela Pawlowska¹ and Pamela Munster¹. ¹University of California San Francisco, San Francisco, CA.

Background: BRCA genes (e.g. BRCA1 and BRCA2) are known to play a major role in tumorigenesis. These genes are key mediators of DNA damage repair response including the homologous recombination repair (HRR) pathway. To leverage impaired DNA repair in tumors, a new class of drugs, the poly (ADP-ribose) polymerase inhibitors (PARPi), were developed and olaparib, niraparib, rucaparib have already been approved as single agents. Efforts to combine these agents with cytotoxic agents showed increased efficacy but overlapping toxicities renders combination therapy difficult to tolerate. Furthermore, the short duration of responses in diseases like breast cancer has further inspired the search for combinations with other agents including epigenetic modifiers.

To overcome those hurdles, we explored synergistic interactions between PARPi and DNA Methyltransferases inhibitors (DNMTi) such as decitabine (a global DNA methyltransferase inhibitor). This cytidine analog, when incorporated in newly synthesized DNA strands (during DNA replication phase (S phase), will trigger a covalent protein-DNA complex formation thereby causing cell cycle arrest and ultimately causing cell death.

Material & Methods: Breast and Ovarian cell lines with/without BRCA mutations are used for in vitro analysis: SUM149PT (Breast, BRCA1 mutated), JHOS-2 & COV362 (Ovary, BRCA1 mutated), KURAMOCHI (Ovary, BRCA2 mutated), MDA-MB-231 (Breast, BRCA Wild-Type), MCF10A (Breast non-tumorigenic cells, BRCA Wild-Type). Combinational effect of talazoparib (PARPi) and decitabine (DNMTi) analyzed by Combenefit® software. Colony assays, cell death analysis, as well as pH2AX level are evaluated. In vivo toxicity analysis has also been done on CD-1 IGS mice.

Results: Our preclinical data in BRCA deficient breast and ovarian cancer cell lines, demonstrated a synergistic inhibition of cell growth and cell death improvement at concentrations of talazoparib and decitabine where each agent individually had minimal efficacy. In cells with intact HRR pathways, the drug combination impact is not significant on the cell death ratio (compared to BRCA deficient cell lines) and only causes a cell growth arrest. The drug combination efficacy is related to a better accumulation of DNA breaks (pH2AX level is higher in the combination group than drug alone groups).

Conclusion: The low drug doses used in these preliminary experiments present a promising therapeutic window for patients with tumors carrying HRR pathway mutations. Ongoing experimentations are also being done in pancreatic cell lines carrying a BRCA mutation as well as CRISPR/Cas9 DNA editing for BRCA1 & 2 in MDA-MB-231 cells. Translational in-vivo studies are currently underway to determine whether synergistic in vitro cytotoxicity translates to anti-tumor efficacy.
Final results from IMPROVE: A randomized, controlled, open-label, cross-over phase IV study to determine the patients' preference for either combined endocrine therapy (exemestane plus everolimus) or immunochemotherapy (capecitabine plus bevacizumab) as first line treatment for advanced HR+/HER2- breast cancer

Christian Martin Kurbacher¹, Ulrike Söling², Antje Hahn³, Marco Chiabudini⁴, Christoph Maintz⁵, Lorenz Rieger⁶, Julia Falkenstein⁴, Eva Runkel⁴, Karin Potthoff⁴ and Thomas Decker⁷.

¹Gynäkologisches Zentrum Bonn, Bonn, Germany; ²Onkologische Gemeinschaftspraxis Dres. Söling/Siehl, Kassel, Germany; ³Klinikum Mittelbaden Baden-Baden Balg, Baden-Baden, Germany; ⁴iOMEDICO AG, Freiburg, Germany; ⁵Hämatologisch-Onkologische Praxis, Würselen, Germany; ⁶Hämatologisch-onkologische Tagesklinik, Landshut, Germany and ⁷Gemeinschaftspraxis für Hämatologie und Onkologie, Ravensburg, Germany.

For patients (pts) with advanced HR+/HER2- breast cancer various treatment options exist. Endocrine therapy or chemotherapy are the recommended 1st-line treatment options according to international guidelines. With comparable efficacy, it is of utmost importance to identify the treatment that has the least negative impact on the pts' quality of life (QoL). Randomized studies to determine the pts' preference (pref) for equi-effective treatment concepts, are lacking. IMPROVE compared both therapeutic concepts by assessing the pts' pref for either a combined antihormonal approach (everolimus /exemestane (E/E)) or chemotherapy (capecitabine /bevacizumab (C/B)).

In total, 77 pts were recruited from 10/14 until 04/17 at 26 sites in GER. Upon diagnosis of locally advanced, inoperable or metastatic disease, pts were randomized to receive 1st-line C/B until disease progression followed by 2nd-line E/E (Arm A) or vice versa (Arm B). Primary objective was the patient-reported pref for either treatment protocol 12 weeks after switching therapy. Key secondary endpoints include PFS, OS, safety and QoL. Descriptive statistics were used to to analyse data, PFS and OS were calculated by using the Kaplan-Meier method.

Baseline characteristics were well balanced with a slightly shorter disease-free interval after primary diagnosis and more prior treatments in Arm B.In Arm A [95% CI], 39% [13.9-68.4] vs 23% [5.0-53.8] of pts preferred E/E compared to C/B, 23% [5.0-53.8] were undecided. In Arm B, 56% [30.8-78.5] vs 11% [1.4-34.7] preferred C/B, 22% [6.4-47.6] undecided. Overall, 42% [24.5-60.9] vs 23% [9.6-41.1] of pts preferred C/B, 23% [9.6-41.1] undecided.

Physicians' pref had a tendency for C/B treatment (Arm A, 62% [31.6-86.1] vs 39% [13.9-68.4] for C/B. Arm B, 56% [30.8-78.5] vs 28% [9.7-53.5] for C/B, no pref 17% [3.6-41.4]).

Median 1st-line PFS [months, 95% CI] was 11.1 [7.8-18.0] for C/B (Arm A) vs 3.5 [2.7-5.5] for E/E (Arm B). Median 2nd-line PFS was 3.7 [2.4-7.8] for E/E (Arm A) vs 3.6 [2.3-5.5] for C/B (Arm B). Median OS [months, 95% CI] was 28.8 [19.7-NA] (Arm A) and 24.7 [13.9-28.8] (Arm B). 73.0% and 52.6% (1st and 2nd line, C/B) vs 54.1% and 52.9% (1st and 2nd line, E/E) of pts developed grade 3/4 AEs. Most common grade 3/4 AEs (%) were hand-foot syndrome (18.9), fatigue (17.6), hypertension (13.5) for C/B and anemia (23.5), fatigue, dyspnoea, cough (each 17.6) for E/E (either line). No treatment-related deaths occurred. Patient-reported QoL (EORTC-QLQC30) and treatment satisfaction were not significantly different between arms in either treatment phase.

In the IMPROVE study, pts had no pref for either endocrine therapy or immunochemotherapy. Overall, there was a tendency in favour of the chemotherapeutic approach (C/B), which was in line with the therapy pref reported by the physicians. C/B was found to have slightly better efficacy results but at the cost of a higher frequency of grade 3/4 AEs, bearing in mind the difference in duration of therapy between the two regimens. Patient-reported QoL, however, was similar in both arms.
Local transdermal therapy (LTT): Drug permeation and distribution of telapristone acetate (TPA) in a pre-surgical window study of women undergoing mastectomy

Oukseub Lee¹, Melissa Pilewskie², Yanfei Xu¹, Kelly Benante¹, Luis Blanco¹, Irene Helenowski¹, Mary Beth Tull¹, Miguel Muzzio³, Borko Jovanovic¹, Scott Karlan⁴, Nora Hansen¹, Kevin Bethke¹, Swati Kulkarni¹, Marjorie Perloff⁵, Eileen P Dimond⁵, Brandy M Heckman-Stoddard⁶ and Seema A Khan¹. ¹Northwestern University, Chicago, IL; ²Memorial Sloan Kettering, New York, NY; ³IIT Research Institute, Chicago, IL; ⁴Cedars-Sinai Medical Center, Los Angeles, CA and ⁵National Institutes of Health, Bethesda, MD.

Background: Low uptake and poor adherence to oral drugs for breast cancer prevention and ductal carcinoma in situ has led to an interest in local routes of delivery with the intent of decreasing systemic exposure and reducing toxicity. LTT has emerged as a possible alternative; previous studies have shown selectively higher concentrations in the breast than in the serum with this delivery route. A question related to LTT is whether or not the drug will permeate and distribute throughout the breast, as is expected with oral delivery.

Methods: We conducted a double-blind study of oral versus LTT delivery of the selective progesterone receptor modulator, telapristone acetate (TPA), in a presurgical window setting, enrolling 82 women planning therapeutic or prophylactic mastectomy. We randomized 67 women 1:1, to oral TPA 12 mg daily, or gel TPA applied to both breasts daily (12 mg/breast), for 4 weeks ±1 week. Mastectomy specimens were sampled at 5 non-tumor locations as well as the tumor and lymph node when available. Samples were split in two: drug concentration (conc.) assay using LC-MS/MS and histological evaluation of tissue composition (fat, fibrous stroma, epithelium). The primary endpoint was mean drug conc. across all breast locations (anticipating that the gel would deliver a mean concentration that was >50% of the mean in the oral group). A secondary endpoint was the drug distribution pattern across the breast, expecting that the distribution would be similar. The tumor sample was saved for biomarker assays related to TPA action; these are ongoing, for a pre-planned pooled analysis of data with NCT01800422 (reported in SABCS abstract 851863).

Results: Of 63 evaluable women (33 oral and 30 gel group), 27 had unilateral and 36 had bilateral mastectomy. The mean drug conc. in the oral group was 166.3 ng/G (SE 11.7), and in the gel group was 10.6 ng/G (SE 10.8), (p<.0001). The conc. was variable across the 7 locations tested in both groups. High concentrations were found in the superficial and deep central locations, retroareolar and lateral locations ranked in the middle, and the medial location was discrepant, being high in the oral and low in the gel group. The variation in drug concentration across all locations was not significantly different between groups (Kolmogorov-Smirnov p=0.99). Among women with bilateral mastectomy, drug concentrations were similar between breasts in both oral and gel groups. In the gel group, despite low TPA concentrations, there was evidence of drug metabolism. The major metabolite, CDB 4453 was detectable in 192/193 samples with detectable parent drug. Analysis of drug concentration adjusted for tissue composition is ongoing.

Conclusions: The gel formulation of TPA did not permeate the skin well. However, the drug delivered to the breast was distributed throughout the breast, similar to the oral delivery route, with the highest concentration in the deep central location. These drug distribution data are novel; drug distribution at multiple locations throughout the breast has not previously been shown. Further work is needed to understand breast distribution with formulations known to have good dermal permeation.
A phase II single arm trial evaluating the efficacy and safety of eribulin in combination with bevacizumab for second-line treatment of human epidermal growth factor receptor 2 (HER2)–negative metastatic breast cancer (MBC) progressing after first-line therapy with bevacizumab and paclitaxel.

Sabino De Placido, Michelino De Laurentiis, Dario Bruzzese, Antonio Bernardo, Edi Editta Baldini, Vincenzo Montesarchio, Alessandra Fabi, Teresa Gamucci, Pietro De Placido, Stefania Russo, Rossella Lauria, Irene De Santo, Claudia De Angelis, Lucia Del Mastro, Mario Giuliano and Grazia Arpino. 1Università degli Studi di Napoli "Federico II", Napoli, NA, Italy; 2Istituto Nazionale Tumori - IRCCS "Fondazione G.Pascale", Napoli, NA, Italy; 3Istituti Clinici Scientifici Maugeri SpA SB, Pavia, PV, Italy; 4Ospedale San Luca, Lucca, LU, Italy; 5Azienda Ospedaliera dei Colli Monaldi, Napoli, NA, Italy; 6IFO - Istituto Nazionale Tumori Regina Elena, Roma, RM, Italy; 7Ospedale 'SS. Trinità', Sora, FR, Italy; 8A.O.U. Santa Maria della Misericordia di Udine, Udine, UD, Italy; 9Azienda Ospedaliera Universitaria Pisana - Ospedale S. Chiara, Pisa, PI, Italy and 10I.R.C.C.S. A.O.U. San Martino - I.S.T., Genova, GE, Italy.

**Background**: At present, there is no standard second-line chemotherapy-based treatment in patients with HER2-negative MBC. Continued VEGF inhibition with bevacizumab is a new potential option in patients progressing to first line bevacizumab and chemotherapy. Eribulin is a non-taxane microtubule dynamics inhibitor, with a unique mechanism of action and suggested beneficial effects on tumor microenvironment and neoangiogenesis. This study evaluated efficacy and safety of eribulin plus bevacizumab as a novel second-line chemotherapy scheme, in patients progressing after first line paclitaxel and bevacizumab.

**Methods**: This is a multicenter, single-arm, Simon's two-stage, Phase II study. Patients with HER2-negative MBC progressing to paclitaxel and bevacizumab received eribulin (1.23 mg/m² intravenously on Days 1 and 8 of every 21-day cycle) plus bevacizumab (10 mg/kg every 2 weeks or 15 mg/kg every 3 weeks intravenously), as second-line chemotherapy. The primary endpoint was the overall response rate (ORR), considered as sum of partial (PR) and complete response (CR), basing on the best overall response. The present safety and efficacy analyses, as planned per study design, refer to six cycles of treatment (18 weeks).

**Results**: Among the 61 patients enrolled in the study, 55 (90,2%) were evaluable for efficacy. ORR (PR/CR) was 9.1% [95% confidence intervals (C.I.) 3.0 to 19.9]; stable disease (SD) rate was 63.6% [95% C.I. 49.6 to 76.2]; clinical benefit rate (CR/PR/SD) at 24 weeks was 35% [95% C.I. 22.0 to 49.1]. The median progression free survival was 6.3 months [95% C.I. 4.1 to 7.8 months]. Drugs-related adverse events (AEs) were: 49.5% related to eribulin, 7.7% related to bevacizumab, and 11.8% related to both the study drugs. The most common AEs were fatigue (9.9% of all AEs), paresthesia (6.5% of all AEs) and neutropenia (6.2% of all AEs). Quality of life was well preserved among the majority of patients.

**Conclusions**: The results of our trial suggest that continuing bevacizumab in combination with eribulin, beyond first line treatment with bevacizumab and paclitaxel, offers a reasonable therapeutic option for patients with HER2-negative MBC, without detrimentally affecting quality of life.
Targeting Rac/Cdc42 in human epidermal growth factor receptor 2 (HER2)-positive breast cancer

Michael J Rivera-Robles1, Julia I Medina-Vlazquez1, Luis D Borrello-Garcia1, Luis E Velazquez-Vega1, Maria del Mar Maldonado1, Jean Ruiz-Calderon1, Linette Castillo-Pichardo1, Pablo Vivas-Mejia1 and Suranganie Dharmawardhane1. 1University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico.

Breast cancer metastasis, when cancer cells move and establish tumors in distant organs, confounds treatment options. Therefore, there is an unmet need for targeted therapeutics to address metastasis, especially in the intractable HER2 positive (+) breast cancer type. HER2 (+) breast cancer is treated with the monoclonal HER2 antibody trastuzumab and the HER2/EGFR targeting small molecule lapatinib. However, ~20% of early stage breast cancer patients and ~70% of patients with metastatic disease are resistant to trastuzumab. Trastuzumab-resistant breast cancers circumvent HER2 inhibition via bypass signaling, which includes the PI3-K/Akt/mTOR pathway. HER2/EGFR and PI-3K/Akt signaling activate the Rho GTPases Rac and Cdc42, and overexpression of Rac or its downstream effector p21-activated kinase (PAK) significantly diminishes response to anti HER2 therapy and patient survival. Therefore, targeting Rac and Cdc42, pivotal regulators of cancer cell migration/invasion, and thus, metastasis, is a viable option to overcome HER2/EGFR therapy resistance. First, we designed and developed the Rac inhibitor EHop-016 (US patents 8,884,006 B2, 9,278,956B1), which inhibits Rac activation with an IC50 of 1 µM and reduces breast cancer growth and metastasis in mouse models of trastuzumab resistant HER2 (+) breast cancer. A more potent dual Rac and Cdc42 inhibitor, MBQ-167 (US Patent 9,981,980 B2), inhibits Rac and Cdc42 activation with IC50s of 103 nM and 78 nM, respectively. In vivo, MBQ-167 inhibits trastuzumab resistant HER2 (+) mammary tumor growth and metastasis by ~90-100% (Humphries-Bickley et al. 2017, Mol Cancer Therap). Therefore, Rac/Cdc42 inhibition blocks cell proliferation, cell cycle progression, migration, and induces apoptosis to ultimately impede tumor growth and metastasis in trastuzumab resistant HER2 (+) breast cancer models. To further investigate the role of Rac/Cdc42 inhibitors in overcoming HER2 therapy resistance, we developed a lapatinib resistant variant of the SKBR3 HER2 (+) breast cancer cell line and found that Rac was overexpressed and over activated in the therapy resistant variant compared to the parental cells. Accordingly, the Rac/Cdc42 inhibitors overcame lapatinib resistance by decreasing cell viability and inducing apoptosis in parental and SKBR3 therapy resistant variants. Pharmacokinetic analysis in mouse plasma demonstrated that the bioavailability of EHop-016 and MBQ-167 is ~30% with a half-life of 3-4 h. Therefore, to increase the bioavailability of Rac/Cdc42 inhibitors and to facilitate sensitization of trastuzumab therapy, we designed and developed novel nanoliposomal formulations containing Rac/Cdc42 inhibitors with trastuzumab on the outer surface to target HER2 (+) breast cancer cells. This data demonstrates the utility of developing Rac/Cdc42 inhibitors as mono or combined therapy with current targeted therapeutics for HER2 (+) breast cancer.
Repurposing sulindac sulfide as a notch inhibitor to target cancer stem-like cells in triple negative breast cancer

Fokhrul Hossain¹, Deniz Ucar¹, Samarpan Majumder¹, Keli Xu², Yong Ran³, Lisa Minter⁴, Yaguang Xi¹, Matthew Burow⁵, Todd Golde³, Barbara Osborne⁴ and Lucio Miele¹. ¹LSUHSC, New Orleans, LA; ²University of Mississippi, Jackson, MS; ³University of Florida, Gainesville, FL; ⁴University of Massachusetts Amherst, Amherst, MA and ⁵Tulane University, New Orleans, LA.

Triple negative breast cancer (TNBC) is a heterogeneous group of clinically aggressive breast cancers. TNBC patients have a high risk of recurrence and metastasis, and current treatment options remain limited. There is strong evidence supporting the involvement of Notch signaling in TNBC progression. Expression of Notch1 and its ligand Jagged1 correlate with poor prognosis. Emerging evidence suggests that cancer stem-like cells (CSCs) that escape chemo or radiation therapy in TNBC are often Notch-dependent. At the same time, there is evidence that active tumor immunity predicts good response to neo-adjuvant chemotherapy in TNBC. Notch inhibitors, including Gamma Secretase Inhibitors (GSIs) are quite effective in preclinical models of TNBC, where they eliminate CSCs resistant to chemotherapy. However, the success of GSIs in clinical trials is limited by their intestinal toxicity and adverse immunological effects. CD4 and CD8 T-cells, necessary to adaptive tumor immunity, require Notch1 for activation. Our overarching goal is to replace GSIs with agents that lack their systemic toxicity and adverse immunological effects. We identified Sulindac Sulfide (SS), the active metabolite of FDA-approved NSAID Sulindac, as a potential candidate to replace GSI. SS has Gamma Secretase Modifier (GSM) activity. We confirmed that SS inhibits Notch1 cleavage in TNBC cells. SS significantly inhibited mammosphere growth in all human and murine TNBC models we tested: 1) human MDA-MB-231 cells; 2) murine TNBC model C0321, from targeted conditional knockout of Lunatic Fringe (LFng/-); and 3) Two TNBC patient-derived xenograft models, 2K1 and 4IC. In contrast, SS did not inhibit Notch expression or cleavage in murine T cells. In C0321 tumors, which recapitulate human mesenchymal TNBC, we found that SS had remarkable single-agent anti-tumor activity and virtually eliminated Notch1 expression in tumors. SS caused an increase in intra-tumoral CD11c+ dendritic cells, but decreased CD4 cells, which in this model are largely PD-1 positive (exhausted). CD8 cells were modestly increased. SS did not affect the number of tumor infiltrating macrophages or myeloid-derived suppressor cells (MDSC). However, SS blocked the immunosuppressive function of bone marrow-derived MDSC. We are currently investigating the mechanisms of this anti-tumor activity. Our data support further investigation of SS for the treatment of TNBC, with standard of care or with immunotherapy agents. Repurposing an FDA-approved, safe agent for the treatment of TNBC would be significantly easier and more cost-effective than developing unproven investigational agents.
Rates of high risk and malignant lesions incidentally detected in the contralateral breast after large volume displacement oncoplastic breast surgery

Christopher Muse-Fisher¹, Mishan Rambukwella¹, Yuanxin Liang², Stephen Naber² and Abhishek Chatterjee². ¹Tufts University School of Medicine, Boston, MA and ²Tufts Medical Center, Boston, MA.

Background: Given the prevalence of female breast cancer in the United States, large volume displacement (Level II) oncoplastic breast surgery is becoming an increasingly common technique to remove cancerous breast tissue. It allows for the removal of the cancerous tissue with a large partial mastectomy followed by a mastopexy or breast reduction oncoplastic reconstruction design. A contralateral symmetry operation using similar mastopexy or breast reduction designs are many times also performed, often by a plastic surgeon. Our goal was to determine the rates of high risk and malignant lesions present in the contralateral breast specimen.

Methods: We conducted a retrospective chart review of the first consecutive 100 large volume displacement oncoplastic breast surgeries performed at our institution between August 2015 and June 2018. Of the 100 cases, 84 patients had an immediate symmetry operation performed on the contralateral breast. Our inclusion criteria for malignant lesions included invasive ductal carcinoma (IDC) and ductal carcinoma in situ (DCIS). Inclusion criteria for high risk lesions included atypical ductal hyperplasia (ADH), atypical lobular hyperplasia (ALH) and lobular carcinoma in situ (LCIS). We obtained this information from the patient's pathology report.

Results: Of the 84 patients that underwent a symmetry operation on the contralateral breast, 14 patients (16.7%) had malignant and/or high risk lesions incidentally detected. Two patients (2.4%) had IDC, 1 (1.2%) had DCIS alone, 1 (1.2%) had DCIS with ADH, 6 (7.1%) had ADH alone, 2 (2.4%) had ALH, and 2 (2.4%) had LCIS. For those who had IDC in the contralateral breast, average reported incidental tumor size was 6.5 mm at its largest point. The majority of these lesions (57%) were found when performing in superomedial pedicle inverted T (Wise) skin incision pattern specimens. 3 (21%) were found using the inferior pedicle inverted T (Wise) skin pattern, 2 (14%) were found using the superomedial pedicle circumvertical skin incision pattern, and 1 (7%) was found using the superior pedicle circumvertical skin incision pattern.

Conclusion: The high incidence of cancer and high risk lesions incidentally detected in the contralateral breast highlights the need for consistent histological examination of the contralateral specimen. These results suggest the need for proper orientation of the specimen and good communication between the surgical (often the plastic surgeons performing the symmetry operation) and pathology teams. Such communication is needed to help target any future surgeries that may be required due to positive margins in the contralateral symmetry specimen.
Tumor phenotype and concordance in synchronous bilateral breast cancer in young women

Linda M Pak¹, Shoshana M Rosenberg², Kathryn J Ruddy³, Rulla M Tamimi⁴, Jeffrey Peppercorn⁴, Lidia Schapira⁵, Virginia F Borges⁶, Steven E Come⁷, Ellen Warner⁸, Craig Snow², Laura Collins², Tari A King¹,² and Ann H Partridge². ¹Brigham and Women's Hospital, Boston; ²Dana-Farber Cancer Institute, Boston; ³Mayo Clinic, Rochester; ⁴Massachusetts General Hospital, Boston; ⁵Stanford University, Palo Alto; ⁶University of Colorado Cancer Center, Aurora; ⁷Beth Israel Deaconess Medical Center, Boston and ⁸Sunnybrook Hospital, Toronto, Canada.

Background: Synchronous bilateral breast cancer is rare, with reported incidence from 0.3-12%; the incidence and pattern of bilateral breast cancer among younger women is unknown. Here we report the incidence and phenotypes of bilateral breast cancer in women ≤40 years of age enrolled in the Young Women's Study (YWS) cohort.

Methods: The YWS is a multi-center, prospective cohort study that enrolled women with newly diagnosed breast cancer at age ≤40 years from 2006-2016. Those with synchronous bilateral breast cancer (in-situ and/or invasive) formed our study cohort. Disease characteristics and treatment were obtained by medical record review. Central pathology review was performed to capture histologic features and categorize the tumor phenotype as either luminal A (hormone receptor (HR)+, HER2-, grade 1 or 2), luminal B (HR+, HER2+, or HER2- and grade 3), HER2-type (HR-, HER2+), or triple negative (TNC; HR/HER2-). Tumor phenotypes of bilateral breast cancers were compared and evaluated for concordance.

Results: Among 1302 patients enrolled in the YWS, 20 (1.5%) patients presented with bilateral disease, with median age of diagnosis of 38 years (range 18-40). The majority of patients (13 (65%)) presented with unilateral symptoms and contralateral disease was identified on subsequent imaging. 12 (60%) reported a positive family history of breast cancer and 17 (85%) underwent genetic testing; resulting in the identification of 6 mutation carriers (2 BRCA1, 3 BRCA2, 1 TP53). The majority of patients (15 (75%)) underwent bilateral mastectomy, 1 underwent unilateral mastectomy with contralateral lumpectomy, and 4 underwent bilateral lumpectomy. On pathology, 2 patients had bilateral in-situ disease, 5 had unilateral invasive and contralateral in-situ disease, and 13 had bilateral invasive disease. Of those with bilateral invasive disease, 10 (77%) patients had bilateral luminal tumors and when fully characterized 6 were of the same luminal type. Only one patient had bilateral basal-like breast cancer.

Conclusions: Among a large cohort of young women, only 20 (1.5%) had bilateral disease, and the majority of the invasive tumors were of the luminal phenotype, yet frequently differed by grade or HER2 status; supporting the need for thorough pathologic evaluation of bilateral disease to determine risk and tailor treatment. Overall the low incidence of bilateral disease and preponderance of the luminal phenotype in this population is reassuring.
A pooled analysis of waist and hip circumference and postmenopausal breast cancer

Rui Song\textsuperscript{1}, Molin Wang\textsuperscript{1}, Stephanie A Smith-Warner\textsuperscript{1} and For the Pooling Project of Prospective Studies of Diet and Cancer Investigators. \textsuperscript{1}Harvard T.H. Chan School of Public Health, Boston, MA.

**Background** Many, but not all, epidemiologic studies suggest that waist and hip circumference, and waist-to-hip ratio (WHR) are positively associated with postmenopausal breast cancer. However, results are inconsistent for breast cancer subtypes, by strata of body mass index, or after adjustment for body mass index. We evaluated these associations in 10 prospective cohorts in the Pooling Project of Prospective Studies of Diet and Cancer.

**Methods** These analyses included 256,214 postmenopausal women among whom 10,738 (N=1,346 estrogen receptor (ER)- and 6,587 ER+ tumors) were diagnosed with breast cancer during follow-up ranging up to 8-20 years. Study-specific, multivariable-adjusted hazard ratios (HR) were calculated for risk of breast cancer overall and by ER status using Cox proportional hazards regression analyses and controlled for age, race, education, height, reproductive factors, physical activity, smoking status, energy and alcohol intake, and family history of breast cancer. Pooled estimates were computed using random-effects models.

**Results** The medians across studies ranged from 76.0-88.3 cm for waist circumference, 98.0-104.8 cm for hip circumference, and 0.77-0.84 for WHR. As expected, preliminary analyses showed stronger, positive associations for all three exposures for women who had never used hormone replacement therapy (HRT) compared to women who had used HRT (P for interaction <0.05). Subsequent results are presented only for never users of HRT. For waist circumference, the pooled HR of overall breast cancer was 1.58 (95% confidence interval [CI] 1.44-1.74) for women with waist circumference $\geq$100 cm compared to 70-80 cm. The corresponding pooled HRs were 1.65 (95% CI 1.45-1.86) for ER+ and 1.38 (95% CI 1.03-1.84) for ER- breast cancer. The associations for hip circumference and WHR were weaker than those observed for waist circumference. The pooled HR for women with hip circumference $\geq$110 cm compared to 95-100 cm was 1.22 (95% CI 1.11-1.35) for breast cancer risk overall. The HRs for ER+ and ER- tumors were 1.27 (95% CI 1.12-1.43) and 1.04 (95% CI 0.78-1.38), respectively. For WHR, the pooled HRs in women with WHR>0.90 compared to 0.75-0.80 were 1.37 (95% CI 1.23-1.52) for overall breast cancer, 1.33 (95% CI 1.15-1.53) for ER+, and 1.29 (95% CI 0.94-1.77) for ER- breast cancer. The findings for ER+ and ER- tumors were significantly different for waist and hip circumference (P-value, test for common effects < 0.05). After additionally adjusting for body mass index, the associations for all three exposures were attenuated and only the associations for waist circumference and WHR for overall and ER+ breast cancer remained statistically significant. Similar positive associations were observed for waist circumference across strata of body mass index; the HRs (95% CI) for a 5 cm increment were 1.06 (1.03-1.09) for women with body mass index $<\text{25 kg/m}^2$ and 1.04 (1.02-1.06) for women with body mass index $\geq\text{25 kg/m}^2$.

**Conclusions** In postmenopausal women who had not used HRT, higher waist circumference, hip circumference and WHR were associated with a modestly higher risk of breast cancer. Results were stronger for ER+ than ER- tumors for waist and hip circumference and did not vary by body mass index for all three exposures.
Trilaciclib (T), a CDK4/6 inhibitor, dosed with gemcitabine (G), carboplatin (C) in metastatic triple negative breast cancer (mTNBC) patients: Preliminary phase 2 results

1Texas Oncology Baylor Sammons, US Oncology Research, Dallas, TX; 2Florida Cancer Specialists (North), Saint Petersburg, FL; 3 Comprehensive Cancer Centers of Nevada, US Oncology Research, Las Vegas, NV; 4Virginia Oncology Specialists, US Oncology Research, Norfolk, VA; 5Oncology Institute of Vojvodina, University of Novi Sad, Sremsska Kamenica, Serbia; 6Saint Luke's Cancer Institute, Kansas City, MO; 7Innovative Clinical Research Institute, Whittier, CA; 8Moffitt Cancer Center, Tampa, FL; 9Tennessee Oncology – Chattanooga, Chattanooga, TN; 10County Hospital Varazdin, Varazdin, Croatia; 11University Clinic of Radiotherapy and Oncology, Skopje, Macedonia, The Former Yugoslav Republic of; 12Rocky Mountain Cancer Centers, US Oncology Research, Denver, CO; 13Texas Oncology Tyler, US Oncology Research, Tyler, TX; 14Texas Oncology San Antonio Northeast, US Oncology Research, San Antonio, TX; 15Clinical Center Nis, Clinic of Oncology, Niš, Serbia; 16G1 Therapeutics, Research Triangle Park, NC and 17Levine Cancer Institute, Atrium Health, Charlotte, NC.

**Background:** Cytotoxic chemotherapy-induced damage of hematopoietic stem and progenitor cells (HSPCs) results in acute toxicities consisting of multi-lineage myelosuppression, and late onset toxicities consisting of progressive bone marrow suppression with increased incidence of therapy-related myeloid neoplasms. T is an IV CDK4/6 inhibitor in development to preserve HSPC and immune system function during cytotoxic chemotherapy (myelopreservation). Proof of concept for myelopreservation with T was observed in a randomized, placebo-controlled Phase 2 trial in small-cell lung cancer patients receiving 1st-line chemotherapy. This trial in mTNBC patients (NCT02978716) was designed to explore the utility of T in combination with GC.

**Methods:** This Phase 2, randomized, open-label study enrolled patients in the US and EU with mTNBC who had received 0-2 prior systemic cytotoxic therapies in the locally recurrent or metastatic setting and had no symptomatic brain metastases. Patients were randomized (1:1:1) to GC alone (Group 1) or T plus GC (Group 2) using a standard schedule (D1, 8 every 21 days) or to an alternative schedule (T on D1, 2, 8 and 9 with GC on D2 and 9 every 21 days; Group 3). On those days when both T and GC were scheduled, T was administered iv prior to GC infusion. Prophylactic growth factors were not administered in cycle 1; otherwise supportive care was allowed as needed. Primary objectives were safety and tolerability; tumor response was evaluated using RECIST v1.1 and PFS and OS were assessed. Myelopreservation endpoints reflecting the potential effects of T on multiple cellular lineages include occurrence of Grade 4 neutropenia (primary), RBC and platelet transfusions (primary), and lymphocyte counts with immune profiling (secondary and exploratory). A signature of CDK4/6 independence developed from preclinical data will be used to evaluate archival tumor tissue samples and data analysis is ongoing.

**Results:** 95 patients were dosed; median age 57 years (range 32-86), ECOG PS 0 (53%) or 1 (47%), 25% had liver metastases at baseline, and approximately 50% had received no systemic therapy in the recurrent/metastatic setting. Fifty-five patients remain on treatment. Disease progression was the most common reason for drug discontinuation (22/40; 55%). Overall the most common (≥25%) TEAEs were anemia (47%), nausea (35%), fatigue (34%), neutropenia (32%), platelet count decreased (25%), and vomiting (25%). The most frequent (≥15%) Grade 3 or 4 TEAEs were hematologic toxicities, i.e. neutropenia (28%), anemia (21%), neutrophil count decreased (21%) and thrombocytopenia (16%). These were also the most frequent drug-related TEAEs observed. Tumor efficacy data are being evaluated.

**Conclusions:** This trial, assessing the myelopreservation effects of T when combined with GC in patients with mTNBC, has completed enrollment. Myelopreservation data, immune profiling, as well as ORR and preliminary PFS results will be presented by study arm at the meeting.
Single agent activity of U3-1402, a HER3-targeting antibody-drug conjugate, in HER3-overexpressing metastatic breast cancer: Updated results of a phase 1/2 trial

Norikazu Masuda¹, Kan Yonemori², Shuji Takahashi³, Takahiro Kogawa⁴, Takahiro Nakayama⁵, Hirotaka Iwase⁶, Masato Takahashi⁷, Tatsuya Toyama⁸, Toshiaki Saeki⁹, Shigehira Saji¹⁰, Kenichi Inoue¹¹, Hiroshi Onuma¹², Naoyuki Tajima¹², Yoshinobu Shiose¹², Shuquan Chen¹³, Ferdinand Guevara¹³, Channing Yu¹³, Suguru Ueno¹² and Hiroji Iwata¹⁴. ¹National Hospital Organization Osaka National Hospital, Osaka, Japan; ²National Cancer Center Hospital, Tokyo, Japan; ³The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan; ⁴National Cancer Center Hospital East, Chiba, Japan; ⁵Osaka International Cancer Institute, Osaka, Japan; ⁶Kumamoto University Hospital, Kumamoto, Japan; ⁷National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan; ⁸Nagoya City University Graduate School of Medical Sciences, Aichi, Japan; ⁹Saitama Medical University International Medical Center, Saitama, Japan; ¹⁰Fukushima Medical University Hospital, Fukushima, Japan; ¹¹Saitama Cancer Center, Saitama, Japan; ¹²Daiichi Sankyo Co., Ltd., Tokyo, Japan; ¹³Daiichi Sankyo, Inc., Basking Ridge, NJ and ¹⁴Aichi Cancer Center Hospital, Nagoya, Japan.

Background: Human epidermal growth factor receptor 3 (HER3) is overexpressed in a variety of solid tumors, including breast cancer. However, there are no approved HER3-targeted anti-cancer therapies. U3-1402 is a HER3-targeted antibody drug conjugate with a novel peptide-based cleavable linker attached to a potent topoisomerase I inhibitor payload. It has a high drug-to-antibody ratio (7:1 to 8:1), a novel linker which is stable in plasma and selectively cleaved by lysosomal cathepsins up-regulated in cancer cells, and a payload with a short systemic half-life. The ongoing, phase 1/2 study (NCT02980341) was initiated to evaluate the safety, tolerability, and efficacy of U3-1402 in HER3-overexpressing metastatic breast cancer (MBC). The study has 3 parts: Dose Escalation, Dose Finding, and Dose Expansion. Here we report updated results from Dose Escalation and Dose Finding.

Methods: In Dose Escalation, the dose of U3-1402 was escalated based on dose-limiting toxicity data (between 1.6 and 8.0 mg/kg) and guided by the modified Continuous Reassessment Method. In Dose Finding, patients were treated with 1 of 2 doses (4.8 mg/kg or 6.4 mg/kg) identified during Dose Escalation. In both parts, U3-1402 was administered via IV infusion in 21-day cycles. The primary objectives were to determine the safety and tolerability of U3-1402, the maximum tolerated dose (MTD), and the recommended dose for expansion. Efficacy assessments included investigator-assessed objective response rate (ORR; proportion of complete response [CR] + partial response [PR]) per RECIST v1.1 and disease control rate (DCR; proportion of CR + PR + stable disease). Efficacy-evaluable patients received ≥1 dose of U3-1402 and had pre- and post-treatment tumor assessments. Pharmacokinetics and the anti-drug antibodies were also assessed.

Results: As of 1 June 2018, a total of 42 patients received U3-1402 across Dose Escalation and Dose Finding (34 and 8 patients, respectively). Overall, 12 patients have discontinued treatment (9 due to progressive disease, 1 due to clinical progression, 1 due to Grade 2 pneumonitis, and 1 due to withdrawal of consent). A total of 30 patients remain on treatment (33.3% [14/42] for ≥6 months). The median (range) age was 54.5 (30–81), and majorities of patients had an ECOG performance status of 0 (76.2%; 32/42) and had received ≥5 prior anti-cancer regimens (78.6%; 33/42). Among efficacy-evaluable patients, the ORR was 46.3% (19/41) and the DCR was 90.2% (37/41). Grade ≥3 treatment-related AEs (TEAEs) were reported in 61.9% (26/42) patients. TEAEs (>50% in treated patients) regardless of causality (any grade, Grade ≥3) included nausea (83.3%, 4.8%), thrombocytopenia (71.4%, 33.3%), decreased appetite (64.3%, 7.1%), neutropenia (59.5%, 26.2%), and leukopenia (57.1%, 19.0%). The MTD was not reached; dose limiting toxicities included events of decreased platelet count and increases in AST or ALT.

Conclusions: In a preliminary analysis of this ongoing phase 1/2 clinical trial, U3-1402 demonstrated antitumor activity in a substantial number of heavily pretreated HER3-expressing MBC patients, and U3-1402 treatment was associated with a manageable safety profile.
Nuclear localization of intracellular domain of LDL receptor-related protein 1B predicts poor outcome in breast cancer; putative relation to NEAT1 mediated mammary gland carcinogenesis

Yoshimi Asano¹, Manabu Futamura¹, Tamotsu Takeuchi¹ and Kazuhiro Yoshida¹. ¹Graduate School of Medicine, Gifu University, Gify, Japan.

**Background:** Low-density lipoprotein receptor-related protein 1B (LRP1B) is thought to have a pleiotropic biological function. Notably, intracellular domain of LRP1B is released and transported to nucleus in a γ-secretase dependent fashion; however, pathological property, which is driven by nuclear transport of intracellular domain of LRP1B is largely unclear. In this study, we aimed to unravel the pathological significance of nuclear localization of intracellular domain of LRP1B in mammary gland carcinogenesis. **Aims:** We examine the clinical significance of LRP1B for breast cancer and we clarify mechanism of nuclear localization of LRP1B in invasive ductal carcinoma. **Methods:** Immunohistochemical staining using newly generated antibodies to intracellular domain of LRP1B was used to determine LRP1B expression in 92 invasive ductal carcinomas of the breast. The clinicopathological significance including prognosis value was statistically analyzed. Doxycycline dependent nuclear expression of intracellular domain of LRP1B was established in cultured breast cancer cells. Subsequently, a series of *in vitro* experiments were performed to explore the role of nuclear localized intracellular domain of LRP1B in cultured breast cancer cells. Comprehensive microarray-based analysis followed by quantitative RT-PCR and chromatin immunoprecipitation assay was performed to know the altered molecular signature induced by nuclear localized intracellular domain of LRP1B. **Results:** Non-tumorous mammary duct epithelial cells did not exhibit LRP1B staining, whereas different degrees of LRP1B immunoreactivity were observed in 75 of 92 invasive ductal carcinoma of the breast. LRP1B immunoreactivity was found in surface membrane and cytoplasm of 60 of 92 (65.2%) invasive ductal carcinoma cells, whereas it was detected in nucleus of 15 of 92 (16.3%) cancer cells. Interestingly, nuclear LRP1B immunoreactivity was significantly associated with poor prognosis of the patients, especially with luminal A type breast cancers. Notably, nuclear localized intracellular domain of LRP1B significantly related to status of nodal metastasis in luminal A type breast cancers. Enforced nuclear expression significantly increased Matrigel invasion activity in MCF-7 luminal A breast cancer cells without affecting cell growth. Notably, nuclear expression of intracellular domain of LRP1B decreased transcription of LRP1B. Comprehensive microarray-based analysis demonstrated that nuclear expression of intracellular domain of LRP1B significantly increased the expression of long non-coding RNA nuclear paraspeckle assembly transcript 1 (NEAT1), which facilitates breast cancer invasion with poor survival. **Conclusions:** Present findings indicated that nuclear localized intracellular domain of LRP1B promoted breast cancer progression with a poor prognostic value, possible through NEAT1 pathway. Nuclear transport of intracellular domain of LRP1B could be a therapeutic target for breast cancer patients.
Results from the phase Ib/II clinical trial of bazedoxifene and palbociclib in hormone receptor positive metastatic breast cancer

Rinath Jeselsohn¹, Hao Guo¹, Rebecca Rees¹, William T Barry¹, Cynthia H Barlett², Nadine M Tung³, Ian E Krop¹, Myles Brown¹ and Eric P Winer¹. ¹Dana Farber Cancer Institute, Boston, MA; ²Pfizer INC, New York and ³Beth Israel Deaconess Medical Center, Boston, MA.

**Background:** Despite the efficacy of endocrine treatments (ETs), most patients with ER+ metastatic breast cancer (MBC) will ultimately develop resistance to these treatments. In most cases of endocrine resistance, ER continues to be expressed. About 30% of patients with ER+ MBC acquire an activating ER mutation that confers resistance to aromatase inhibitors. Thus, ER remains an important driver in a substantial number of patients with MBC despite resistance to currently available ETs. Bazedoxifene is a third generation selective ER modulator (SERM) with selective ER degradation (SERD) activity. The structural characteristics of bazedoxifene differ from those of tamoxifen and raloxifene. Pre-clinical studies showed that bazedoxifene has increased ER antagonistic activity compared to tamoxifen and fulvestrant and has synergistic activity in combination with the CDK4/6 inhibitor, palbociclib. We evaluated the safety and efficacy of bazedoxifene in combination with palbociclib in ER+ MBC.

**Methods:** This was a phase Ib/II study of patients with ER+/HER2- MBC who had progressed on at least one line of ET for metastatic disease or within 12 months of adjuvant ET. Treatment included daily continuous bazedoxifene 40mg and palbociclib 125 mg for 21 days out of a 28-day cycle. Primary endpoint was clinical benefit rate (CBR; CR + PR + SD ≥ 24 weeks). Secondary end points included objective response, progression free survival (PFS) and safety. The study used a Simon optimal two-stage design and included a safety run-in phase with the first six patients. The sample size was chosen to have 90% power and a one-sided Type I error of ≤10% to reject the null (CBR of ≤ 20%). A biopsy from a metastatic site was obtained from 21 patients and serial plasma samples were collected from all patients for correlative studies.

**Results:** From July, 2015 to July, 2017 36 patients enrolled in the study (34 females, 2 males). More than 80% of the patients received at least 1 prior line of endocrine treatment for metastatic disease. 45% of the patients received ≥ 2 lines of endocrine treatment and 52% received 1-2 lines of chemotherapy prior to the study. More than 80% of the patients had visceral disease. The combination of bazedoxifene and palbociclib was well tolerated. The most commonly observed adverse events (any grade) were fatigue and neutropenia. Grade 4 adverse events were uncommon (2 patients). The CBR was 36% (95% CI 23-49%). The objective response rate was 8% (95% CI 2-22%). Median PFS was 3.6 months (95% CI 2-8.5 months). There were 5 patients with a durable clinical benefit of ≥12 months. Correlative analysis of the pre-treatment tissue samples and serial plasma samples are ongoing.

**Conclusions:** The combination of bazedoxifene and palbociclib was well tolerated and demonstrated significant clinical activity in heavily pre-treated patients with ER+ MBC. Further studies investigating bazedoxifene in ER+ breast cancer are warranted.
A phase 1b dose-escalation and expansion study of the BCL-2 inhibitor venetoclax combined with tamoxifen in ER and BCL-2–positive metastatic breast cancer (MBC)

Background: Venetoclax, a potent and selective inhibitor of the survival protein BCL-2 (recently approved in CLL and in development in other hematopoietic malignancies), has yet to be evaluated in pts with solid tumors. BCL-2 is overexpressed in ~85% of ER+ breast cancer. Preclinical findings using patient-derived xenograft breast tumor models suggest that venetoclax synergizes with endocrine therapy by increasing apoptosis. Here we report mBEP, an investigator-initiated phase 1b study of venetoclax with tamoxifen in 33 pts with ER+ (>1%), BCL-2+ (>10%, 2-3+ intensity) and HER2– MBC.

Methods: We conducted a 3+3 dose escalation study comprising cohorts receiving venetoclax 200, 400, 600 or 800 mg/d with tamoxifen 20 mg/d (continued until progression). The primary endpoint was to determine the maximum tolerated dose (MTD), define dose-limiting toxicities (DLTs) and identify the recommended phase 2 dose (RP2D). In a dose expansion phase (at the RP2D), secondary endpoints including safety and tolerability, response at 24 wks (RECIST v1.1), clinical benefit rate (CBR) and progression-free survival (PFS) were studied.

Results: In the escalation phase (n=15 pts), treatment was well tolerated with no DLTs or high-grade (Gd 3/4) adverse events observed, apart from asymptomatic on-target lymphopenia (Gd 3, 2/15 pts). MTD was not reached. The 800 mg/d dose was selected as the RP2D and the cohort expanded to include 24 pts with ≥24 wks follow up (range 24-105 wks). Fifteen pts had received prior regimens for MBC (median 3, range 1-9) that included tamoxifen in 5/15. For the RP2D cohort (n=24), overall responses (OR) included 1 CR (4%) and 12 PR (50%), with 5 SD (21%), corresponding to a CBR of 75%. The 9 pts treated in the first line setting experienced a 78% OR (7/9 pts) and 11% SD (1/9 pts), equating to an 89% CBR. The data are immature for determining median PFS for the RP2D cohort (currently 40+ wks).

Treatment responses were pre-empted by metabolic responses (FDG-PET) at 4 wks (seen in 13/16 (81%) pts studied), and correlated with serial changes in circulating tumor DNA (ctDNA). Intriguingly, responses and clinical benefit were observed in pts with plasma-detected ESR1 mutations (4/10 and 7/10, respectively).

The most common treatment-related AEs (CTCAE v4.0) for all pts were lymphopenia in 29/33 (88%; 57% Gd 1-2, 30% Gd 3-4), neutropenia in 24/33 (73%; 67% Gd 1-2, 6% Gd 3), nausea in 22/33 (67%; all ≤Gd 2), anemia in 13/33 (39%; 33% Gd 1-2, 6% G3), thrombocytopenia in 11/33 (33%; all ≤Gd 2), vomiting in 11/33 (33%, all ≤Gd 2), diarrhea in 10/33 (30%; 24% Gd 1-2, 6% Gd 3), infection in 9/33 (27%; 18% Gd 2, 9% Gd 3) and fatigue in 7/33 (21%; all ≤Gd 2). There was one possible treatment-related SAE (infection).

Conclusions: In the first clinical study to evaluate venetoclax in a solid tumor, we demonstrate that combining venetoclax with endocrine therapy has a tolerable safety profile and elicits remarkable activity in ER+ and BCL-2+ MBC. These findings support further investigation of combination therapy for patients with BCL-2-positive breast cancer.

Phase 1/1b study of novel oral selective estrogen receptor degrader (SERD) LSZ102 for estrogen receptor-positive (ER+) advanced breast cancer (ABC) with progression on endocrine therapy (ET)

Komal Jhaveri1, Giuseppe Curigliano2, Yoon-Sim Yap3, Sara Cresta4, Francois P Duhoux5, Catherine Terret6, Shunji Takahashi7, Gary A Ulaner1, Nicole Kundamal8, Daniela Baldoni9, Serena Liao10, Adam Crystal10 and Dejan Juric11. 1Memorial Sloan Kettering Cancer Center, New York, NY; 2University of Milan, Istituto Europeo di Oncologia – IRCCS, Milan, Italy; 3National Cancer Centre Singapore, Singapore, Singapore; 4Fondazione IRCCS – Istituto Nazionale dei Tumori, Milan, Italy; 5Cliniques Universitaires Saint-Luc, Brussels, Belgium; 6Centre Léon Bérard, Lyon, France; 7The Cancer Institute Hospital of JFCR, Tokyo, Japan; 8Novartis Institutes for Biomedical Research, East Hanover, NJ; 9Novartis Pharma AG, Basel, Switzerland; 10Novartis Institutes for Biomedical Research, Cambridge, MA and 11Massachusetts General Hospital, Boston, MA.

Background: LSZ102 is an orally bioavailable SERD that inhibits ER gene transcription, induces receptor degradation, and blocks ER-dependent cell growth in preclinical models. This study is evaluating LSZ102 as a single agent and in combination with the CDK 4/6 inhibitor ribociclib (LEE011) or the PI3K inhibitor alpelisib (BYL719) in patients (pts) with ER+ ABC. The LSZ102 single agent data are presented below; combination data are not discussed.

Methods: In the dose-escalation phase evaluating single-agent LSZ102 (Arm A), pts (age ≥18 years; ECOG PS 0-1) with histologically confirmed ER+ ABC and progression on endocrine therapy (ET) received LSZ102. The starting dose was 200 mg once daily. The primary objective of Arm A was to characterize the safety and tolerability of LSZ102 and identify a recommended dose for expansion (RDE). Secondary objectives included preliminary antitumor activity and pharmacokinetics (PK).

Results: As of January 22, 2018, 57 pts were enrolled to Arm A (LSZ102 200 mg, n=4; 400 mg, n=6; 450 mg fasted, n=15; 450 mg with food, n=6; 600 mg, n=20; 900 mg, n=6). Median age was 60 years, 75% (n=43) of pts had an ECOG PS of 0, 56% (n=32) had received prior fulvestrant, and 58% (n=33) had received prior CDK4/6 inhibitors; median number of prior lines of therapy (all settings) was 6. At data cut-off, 48 pts had discontinued treatment, most (n=45, 94%) due to disease progression. Dose-limiting toxicities across treatment groups included diarrhea (2 pts in the 900-mg group), vomiting (1 pt in the 600-mg group), and AST and ALT elevation (1 pt in the 450-mg with food group). The most common treatment-related adverse events (AEs) in the treatment period were diarrhea (60%), nausea (56%), and vomiting (30%). In the treatment period, treatment-related grade 3 AEs (12%) were infrequent, and there were no such grade 4 events. Six pts (11%) required dose reduction due to AEs (nausea, vomiting or diarrhea); 4/6 of the dose reductions occurred at 900 mg. Preliminary PK assessment showed rapid absorption and dose-proportional increases in LSZ102 exposure; trough concentrations were above the predicted tumorostatic concentrations at doses of ≥400 mg. Based on PK results for the 450-mg fasted and fed cohorts, LSZ102 exposure does not appear to be affected by dosing with a regular meal. Evidence of ER modulation by immunohistochemistry was observed in paired baseline and on-treatment biopsies. 18F-fluorooestradiol positron emission tomography (FES-PET) analysis (n=6) demonstrated abrogation of FES-PET signal for pts in the 450-mg and 600-mg dose groups. Seventeen pts (29.8%) had a best response of stable disease, and 1 pt, who happened to be in the 600-mg group, achieved a partial response.

Conclusion: In heavily pretreated pts, LSZ102 was well tolerated, demonstrated antitumor activity, and achieved effective exposure levels based on PK and pharmacodynamics. Food intake did not appear to significantly alter the PK profile of LSZ102. Dose escalation for LSZ102 in combination with ribociclib or alpelisib is ongoing and will be reported in a future analysis. An update on the recommended single agent dose and schedule will be presented.
Phase 2 safety and efficacy results of TAK-228 in combination with exemestane or fulvestrant in postmenopausal women with ER-positive/HER2-negative metastatic breast cancer previously treated with everolimus

Jennifer R Diamond1, David Potter2, Mohamad Salkeni3, Paula Silverman4, Tufia Haddad5, Frederic Forget6, Ahmad Awada7, Jean-Luc Canon8, Michael Danso9, Alain Lortholary10, Hugues Bourgeois11, Elizabeth Tan-Chiu12, Chirag Patel13, Rachel Neuwirth13, E Jane Leonard13 and Bora Lim14.

1University of Colorado Cancer Center, Aurora, CO; 2University of Minnesota, Minneapolis, MN; 3West Virginia University, Morgantown, WV; 4University Hospitals Cleveland Medical Center, Cleveland, OH; 5Mayo Clinic, Rochester, MN; 6Centre Hospitalier de l'Ardenne, Libramont, Belgium; 7Institut Jules Bordet, Université Libre de Bruxelles, Bruxelles, Belgium; 8Grand Hôpital de Charleroi, Charleroi, Belgium; 9Virginia Oncology Associates – Hampton, Chesapeake, VA; 10Centre Catherine de Sienne, Nantes, France; 11Clinique Victor Hugo - Centre Jean Bernard, Sarthe, France; 12Florida Cancer Research Institute, Plantation, FL; 13Millennium Pharmaceuticals, Inc., a Wholly Owned Subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA and 14M.D. Anderson Cancer Center, Houston, TX.

**Background:** TAK-228 is an investigational, oral and highly selective ATP-competitive inhibitor of TORC1/2. Targeting the PI3K/AKT/mTOR pathway with the dual TORC1/2 inhibitor TAK-228 may restore sensitivity to endocrine therapies in patients (pts) with breast cancer who have progressed on the combination of an endocrine agent plus a TORC1 inhibitor. Here we report data from the phase 2 portion of a phase 1b/2 study of TAK-228 plus exemestane (E) or fulvestrant (F).

**Methods:** Postmenopausal women with ER+ and HER2-, inoperable or metastatic breast cancer (MBC) following everolimus (EVE) plus E or F after progression, received oral TAK-228 (4 mg QD) plus E (25 mg QD) or F (500 mg monthly) for 28-day cycles until progressive disease (PD) or unacceptable toxicity (NCT02049957). Pts were enrolled into parallel cohorts based on prior response to EVE plus E or F and were given the same prior therapy (E or F) at their established dose: EVE-sensitive, defined as disease progression after complete response (CR), partial response (PR), or ≥6 mos stable disease (SD); or EVE-resistant, defined as disease progression without a CR or PR, or after <6 mos SD. Primary endpoint was clinical benefit rate at 16 wks (CR, PR, or SD at 16 wks; CBR-16). Secondary endpoints included CBR at 24 wks (CBR-24), overall response rate (ORR), progression-free survival (PFS), overall survival (OS) and safety.

**Results:** From Oct 2015 to Dec 2017, 94 pts were enrolled. Median age was 58 y (range 32–83). At baseline, most pts (67%) had stage IV disease and others were stage IA–IIIC (24%), other (3%) or unknown (5%); 94% of EVE-sensitive (93% E vs 100% F) and 88% of EVE-resistant pts (91% E vs 75% F) had received ≥4 prior lines of therapy. Pts received a median of 3 cycles (1–15) of TAK-228. At data cutoff (24 Apr 2018), 98% of pts had discontinued treatment, mainly due to PD (76%) or adverse events (AEs; 14%). CBR-24 was 41% (n=21) in EVE-sensitive and 26% (n=11) in EVE-resistant pts (table). CBR-24 was 24% in EVE-sensitive (19% E vs 50% F) and 23% in EVE-resistant (23% E vs 25% F) pts. Eleven of 21 pts who achieved CBR-24 also achieved CBR-24 (6 SD, 5 PR) in the EVE-sensitive cohort and 8 of 11 pts in the EVE-resistant cohort (6 SD, 2 PR). The ORR was 12% in EVE-sensitive pts and 9% in EVE-resistant pts (table). Median PFS (95% CI) was 4.1 mos (2.2–5.5) and 3.4 mos (1.9–5.4), and median OS (95% CI) was 15.9 mos (14.1–19.5) and 14.0 mos (13.0–16.0) in the EVE-sensitive and -resistant cohorts, respectively. Drug-related any grade and grade ≥3 AEs were seen in 90% and 29% of pts, respectively. Most common drug-related any grade AEs were nausea (50%), fatigue (38%), hyperglycemia and diarrhea (each 29%); 22% of pts reported a serious AE. No deaths were reported. Treatment is ongoing in two pts.

**Conclusion:** TAK-228 plus E or F showed modest clinical benefit in pts with previously treated, EVE-sensitive or -resistant MBC, with an acceptable safety profile.

Background: Palbociclib is approved for treatment of ER+, HER2- ABC at a standard dose of 125 mg po daily 3 weeks on/1 week off (STD). We evaluated the efficacy, safety, quality of life (QOL) and compliance of a 100 mg continuous daily dose (CDD) of palbociclib based on modeling data that suggested efficacy and tolerability.

Methods: Canadian Cancer Trials Group (CCTG) led a randomized phase II trial (CCTG MA38) to estimate the efficacy of palbociclib 100 mg po on CDD schedule (Arm 1) relative to 125 mg po STD schedule (Arm 2) with physician choice endocrine therapy. Eligible patients had ER+, HER2- ABC, post progression on first line metastatic endocrine therapy or progressed while on/within 12 months of completion of adjuvant endocrine therapy. One line of palliative chemotherapy in ABC was allowed. Stratification factors were: visceral metastases, duration of prior endocrine therapy and planned endocrine therapy. Primary Outcome measure was investigator reported PFS; secondary outcome measures included: RR, OS, safety (CTCAE V4.0), and QOL (EORTC QLQ-C30). The sample size was 180 to enable estimation of the HR between arms with the upper bound of the 90% CI 1.36 times the estimated HR and the lower bound is 0.74 times the estimated HR.

Results: 180 patients were enrolled across Canada from Dec 2015 to Feb 2017. The database was locked April 16 2018 after prespecified PFS events reached at a median follow-up of 19 months for all patients. For the whole population: median age was 60.5 years (21% ≥ 70 years); ECOG 0/1 95%; postmenopausal 91%; visceral metastases 67%. Planned endocrine therapy: aromatase inhibitor 33%, fulvestrant 57%, tamoxifen 10%. Efficacy analyses CDD vs STD: PFS stratified univariate HR 0.93 (90% CI 0.66-1.30); multivariate Cox model analysis (covariates ECOG PS, age, histology, grade): HR 0.92 (90% CI 0.67-1.25). Median PFS CDD: 9.33 months (90% CI 6.93-13.90) and STD: 11.30 months (90% CI 8.08- 13.83) Secondary analyses CDD vs STD: OS stratified univariate HR: 1.07 (90% CI 0.67-1.69); multivariate HR 1.14 (90%CI 0.75-1.75); median OS for CDD: 20.73 months (90% CI 19.29-23.30) and 21.39 months (90% CI 19.65 to 26.68) for STD. RR and median duration of response: 11.1% vs 12.4% (p=0.84) and 126 vs 169 days (p=0.86), respectively. Palbociclib drug exposure CDD vs STD: median daily dose (mg) 87 vs 125; median dose intensity (mg/week) 571.2 vs 613.5; ≥ 90% planned dose intensity, 41% vs 54%. Dose modification (withhold and/or reduction) rate CDD vs STD for neutropenia was 70% vs 40%. Grade 3/4 neutropenia 69% vs 53%; febrile neutropenia 3% each arm. Non-hematological toxicity profiles were comparable for both arms. No significant differences were seen in QOL domains.

Conclusion: Palbociclib is active and tolerable when administered on either a 100 mg CDD or a 125 mg STD schedule. CDD schedule had higher rates of grade 3/4 neutropenia and dose modifications. Post approval evaluation of alternate dosing schedules for targeted therapies provides useful information regarding drug activity, toxicity and adherence.
nextMONARCH 1: Phase 2 study of abemaciclib plus tamoxifen or abemaciclib alone in HR+, HER2- advanced breast cancer

Erika Hamilton¹, Javier Cortes²,³, Veronique Dieras⁴, Ozgur Ozyiilkan⁵, Shin-Cheh Chen⁶, Katarina Petrankova⁷, Aleksey Manikhas⁸, Guy Jerusalem⁹, Roberto Heggi⁰, Yi Lu¹¹, Melissa M Bear¹¹, Erica L Johnston¹¹ and Miguel Martin¹². ¹Sarah Cannon Research Institute, Tennessee Oncology PLLC, Nashville; ²Ramon y Cajal University Hospital, Madrid, Spain; ³Vall d’Hebron Institute of Oncology, Barcelona, Spain; ⁴Centre Eugene Marquis UNICANCER, Rennes Cedex, France; ⁵Baskent University, Adana, Turkey; ⁶Chang Gung Memorial Hospital, Linkou, Taoyuan City, Taiwan; ⁷Masarykuv Onkologický Ustav, Brno, Czech Republic; ⁸City Clinical Oncology Dispensary, St. Petersburg, Russian Federation; ⁹Centre Hospitalier Universitaire, Liege, Belgium; ¹⁰Hospital Pérola Byington/FMUSP, Centro de Referência da Saúde da Mulher, São Paulo, Brazil; ¹¹Eli Lilly and Company, Indianapolis and ¹²Instituto de Investigación Sanitaria Gregorio Marañón, Universidad Complutense, CIBERONC, Madrid, Spain.

Background
Abemaciclib is a selective CDK4 & 6 inhibitor approved on a continuous dosing schedule for HR+, HER2- advanced breast cancer (ABC) as monotherapy (MONARCH 1) and in combination with endocrine therapy (ET). A previous Phase 1b (NCT01394016) cohort of HR+ ABC patients (pts) demonstrated efficacy of abemaciclib monotherapy (150mg and 200mg Q12H starting dose); given the small sample size and nonrandomized design the impact of the starting dose was unclear.

nextMONARCH 1 (NCT02747004) evaluated abemaciclib in 2 monotherapy arms, in a randomized setting. Abemaciclib has been associated with dose-dependent early onset diarrhea that is well managed with antidiarrheal therapy. nextMONARCH 1 also explored the 200mg Q12H abemaciclib dose in combination with prophylactic loperamide to reduce incidence/severity of diarrhea and dose adjustments. A third arm evaluated abemaciclib + tamoxifen as a strategy to overcome endocrine resistance.

Methods
nextMONARCH 1 is a multicenter, randomized, open-label, Phase 2 study of abemaciclib or abemaciclib + tamoxifen in women with HR+, HER2- ABC who have progressed on or after prior ET and previously received chemotherapy. Pts were stratified by presence of liver metastases and prior use of tamoxifen in the advanced setting. Randomization was 1:1:1 to abemaciclib 150mg Q12H + daily tamoxifen 20mg (Arm A) or abemaciclib 150mg Q12H (Arm B); or abemaciclib 200mg Q12H + prophylactic loperamide (Arm C). Key eligibilities were ≥2 chemotherapy regimens (1-2 administered in metastatic setting), measurable disease and no prior treatment with CDK4 & 6 inhibitors. Primary objective was progression free survival (PFS). Key secondary objectives included objective response rate (ORR), dCR (clinical benefit rate (CBR), and safety. PFS analysis tested superiority of Arm A to C at ~110 events across the 2 arms assuming a hazard ratio (HR) of 0.667 to achieve ~80% power. Arm B would be considered non-inferior to Arm C if the observed PFS HR is <1.2.

Results
234 pts were randomized to Arms A (n=78), B (n=79) and C (n=77). 166 PFS events have been observed (A: 57; B: 54; C: 55). Median PFS was 9.1 months in Arm A, 6.5 in Arm B and 7.4 in Arm C (A vs C: HR=.815, 95% CI, .556-1.193, p=.293; B vs C: HR=1.045, 95% CI, .711-1.535 p=.811). Investigator-assessed ORR was 34.6%, 24.1% and 32.5% (confirmed ORR: 25.6%, 19.0%, 28.6%) and CBR was 61.5%, 49.4% and 51.9% in Arms A, B and C, respectively. Prophylactic loperamide reduced the incidence and severity of diarrhea (C: 62.3%, Gr 3: 7.8%) compared to MONARCH 1 (90.2%, Gr 3: 19.7%, Dickler et al. 2017) resulting in similar rates of diarrhea with 150mg abemaciclib without prophylaxis (A: 53.8%, Gr 3: 1.3%; B: 67.1%, Gr 3: 3.8%). The adverse event profile across arms was generally consistent with other breast studies of abemaciclib.

Conclusions
nextMONARCH 1 confirmed single-agent activity of abemaciclib in heavily pretreated pts with HR+, HER2- ABC. Efficacy of abemaciclib monotherapy at 150mg was similar to 200mg. Combining tamoxifen with abemaciclib did not demonstrate a statistically significant improvement in PFS compared to abemaciclib monotherapy. Addition of prophylactic loperamide to abemaciclib 200mg resulted in diarrhea similar to 150mg without prophylaxis.
Omics profiling of CDK4/6 inhibitors reveals functionally important secondary targets of abemaciclib

Caitlin E Mills¹, Marc Hafner¹, Kartik Subramanian¹, Chen Chen¹, Mirra Chung¹, Sarah A Boswell¹, Robert A Everley¹, Charlotte S Walmsley², Dejan Juric² and Peter K Sorger¹. ¹Harvard Medical School, Boston, MA and ²Massachusetts General Hospital, Boston, MA.

The recent introduction of small molecule inhibitors of cyclin-dependent kinases (CDK) 4/6 to the clinic has improved the treatment of hormone receptor positive breast cancer, and shown promise in other malignancies. The three clinically used CDK4/6 inhibitors, palbociclib, ribociclib, and abemaciclib, are reported to be broadly similar although recent data suggest that abemaciclib has distinct single-agent activity in patients and a unique adverse effects profile. Key questions are: How do these drugs differ at the molecular level? Should such differences inform their use in the clinic? Can these three agents be used interchangeably or should patient stratification differ between them? We use molecular and functional profiling by mRNA sequencing, mass spectrometry-based proteomics, and GR-based dose-response assays to obtain complementary views of the mechanisms of action of CDK4/6 inhibitors. We show that abemaciclib, but not ribociclib or palbociclib, is a potent inhibitor of kinases other than CDK4/6, including CDK1/Cyclin B, which appears to cause arrest in the G2 phase of the cell cycle, and CDK2/Cyclin E/A, which is implicated in resistance to palbociclib. We show that inhibition of these additional targets is accessible in a xenograft model. Whereas ribociclib and palbociclib induce cytostasis, and cells adapt to these drugs within 2-3 days of exposure, abemaciclib induces cell death and durably blocks cell proliferation. Abemaciclib is active even in retinoblastoma protein (pRb)-deficient cells in which CDK4/6 inhibition by palbociclib or ribociclib is completely ineffective. The degree of polypharmacology of small molecule drugs is increasingly viewed as an important consideration in their design, with implications for efficacy, toxicity, and acquired resistance. In the case of CDK4/6 inhibitors, we propose that abemaciclib polypharmacology elicits unique molecular responses. More generally, we propose that multi-omic approaches are required to fully elucidate the spectrum of targets relevant to drug action in tumor cells. We expect such understanding to assist in stratifying patient populations and ordering sequential therapies when resistance arises.
Personalized serial circulating tumor DNA (ctDNA) analysis in high-risk early stage breast cancer patients to monitor and predict response to neoadjuvant therapy and outcome in the I-SPY 2 TRIAL

Mark Jesus M Magbanua¹, Lamorna Brown-Swigart¹, Gillian L Hirst¹, Christina Yau¹, Denise Wolf¹, Aye Aye Ma¹, Elizabeth Bergin¹, Sara Venters¹, Himanshu Sethi³, Hsin-Ta Wu², Raheleh Salari², Tony Tin², Sarah Sawyer², Maggie Louie², Bernhard Zimmermann², Cheng-Ho Jimmy Lin², Jonathan Keats³, Winnie S Liang³, Lori Cuyugan⁵, Daniel Enriquez³, Debasish Tripathy⁴, Amy Jo Chien¹, Andres Forero⁷, Angela DeMichele⁶, Minetta Liu⁶, Amy L Delson¹, Smita Asare¹, Laura Esserman¹, Laura van’t Veer¹ and I-SPY 2 Consortium¹. ¹University of California San Francisco, San Francisco, CA; ²Natera Inc, San Carlos, CA; ³TGEN, Phoenix, AZ; ⁴MD Anderson Cancer Center, Houston, TX; ⁵Mayo Clinic, Rochester, MN; ⁶University of Pennsylvania, Philadelphia, PA and ⁷University of Alabama, Birmingham, AL.

cDNA analysis offers a non-invasive approach for monitoring response and resistance to treatment. Serial ctDNA testing during neoadjuvant therapy (NAT) may provide early indicators of emerging resistance and disease progression. In this study, we analyzed ctDNA from high-risk early breast cancer patients who received NAT and definitive surgery in the I-SPY 2 TRIAL (NCT01042379). We hypothesize that (1) assessment of ctDNA levels early in treatment will improve the performance of molecular and imaging-based predictors of pathologic complete response (pCR) to NAT; and (2) levels of ctDNA after NAT are associated with residual cancer burden and recurrence [distant recurrence free survival (DRFS)].

**Methods:** ctDNA analysis was performed in 84 high-risk stage II and III breast cancer patients randomized to neoadjuvant investigational agent (n=52), AKT inhibitor MK-2206 (M) in combination with paclitaxel (T) followed by doxorubicin and cyclophosphamide (AC) (M+T->AC), or standard-of-care (T->AC) (n=32). HER2+ patients also received trastuzumab (H). Serial plasma was collected before NAT (T0), early treatment (3 weeks, T1), between regimens (12 weeks, T2), and after NAT prior to surgery (T3). Mutational profiles derived from pretreatment tumor biopsy and normal matched DNA whole exome sequencing were used to design personalized assays targeting 16 patient-specific somatic variants to detect ctDNA in serial plasma.

**Results:** Of the 84 patients in this study, 43% were HR-/HER2- (TNBC), 35% HR+/HER2-, and 23% HER2+. In total, 74% (61 of 83), 35% (28 of 79), 14% (9 of 65), and 8% (5 of 61) were positive for ctDNA at timepoints T0, T1, T2, and T3, respectively. At T0, ctDNA positivity and levels (average number of mutant molecules detected per mL) were significantly associated with increased tumor burden (by clinical and MRI examination), more aggressive tumor biology (as reflected in higher MammaPrint scores and grade) and subtype (HER2+ and TNBC). Twenty-seven percent (27%) of the 84 patients achieved a pCR and all patients who were ctDNA-positive at T3 (n=5) did not achieve a pCR. Currently, data are being collected to: (1) assess the relationship of ctDNA and MRI imaging in predicting tumor response to therapy; (2) examine the relationship of ctDNA levels before and after NAT with 3-year DRFS and event-free survival (EFS). The results of these analyses will be presented at the SABCS 2018 meeting.

**Conclusions:** Our study provides a platform to evaluate the clinical significance of ctDNA for serial monitoring of response to NAT. Accurate and early response prediction by highly sensitive ctDNA analysis can facilitate a timely and judicious change in treatment to improve patients’ chances of achieving a pCR. Finally, personalized ctDNA testing may complement imaging and pathologic evaluation of tumor response to fine-tune pCR as a surrogate endpoint for improved DRFS and EFS.
Background: CDK4/6 inhibition combined with endocrine therapy (ET) is now the standard of care for advanced hormone receptor (HR) positive breast cancer patients (pts). Previous ctDNA analysis of paired pre-treatment (pre-T) and end of treatment (EoT) plasma samples from the PALOMA-3 trial of the CDK4/6 inhibitor P with/without F demonstrated that acquired PIK3CA, ESR1, RB1 and rare growth factor receptor mutations (mut) likely contribute to resistance (Turner et al, ASCO 2018, Abstract 1001). We now report results from an extended ctDNA analysis of paired PALOMA-3 plasma samples using hybridization capture-based, next-generation sequencing (NGS) assay covering 87 breast cancer, HR signaling, and cell cycle-related genes.

Methods: Pre-/post-menopausal pts whose disease progressed after prior ET (N=521) were randomized 2:1 to receive F 500 mg + P (125 mg/d, 3 wk on/1 wk off) or placebo. Cell-free DNA extracted from paired plasma samples (n=194) was analyzed with a custom 87-gene NGS assay, to identify single nucleotide variants and copy number amplification (CNA), with molecular barcoding, high NGS coverage (10,000-20,000 reads per nucleotide position), and background error correction. Differences in ctDNA mut frequencies detected in P+F compared to F alone were assessed and their association to clinical outcome estimated.

Results: Blinded assay qualification and droplet digital PCR validation suggested a mut detection frequency cutoff at 0.3%. A high coefficient of correlation with previously presented data was observed for ESR1 and PIK3CA variants (r=0.94 and 0.97, respectively), with acquisition of PIK3CA and ESR1 mutations at EoT in P+F and F groups. Gene level mut analysis of EoT plasma revealed no significant difference between P+F vs F alone (Table), although there was an increase in RB1 mutations in P+F consistent with previous data. Other acquired muts at EoT (SMAD4, NOTCH2, and CDKN1B) were observed at low frequencies. Muts in CDK4 and CDK6 were rarely observed (< 1% of pts), regardless of treatment arm.

Conclusions: Our results corroborate the previously reported results demonstrating that genomic profiles of treatment resistant cancer are similar between P + F and F therapy. Expanded analysis of cell-cycle genes identified no new recurrently mutated genes, and confirmed that RB1 mutations are selected at low frequency after P+F treatment. Alterations in cell cycle genes may not be a common mechanism of resistance to CDK4/6 inhibitors in HR+ HER2- advanced breast cancer.

Circulating tumor DNA (ctDNA) and circulating tumor cells (CTC) predictive value in HER2 negative metastatic breast cancer patients treated with first line weekly paclitaxel and bevacizumab: Results of a prospective cohort from the French Breast Cancer InterGroup Unicancer (UCBG): COMET study

Background: Increased levels of CTC and a persistent elevated level after just one cycle of chemotherapy are very strong and independent markers of worse progression-free survival (PFS) and overall survival (OS) in patients (pts) with metastatic breast cancer (MBC) (Bidard et al, Lancet Oncol 2014). ctDNA can be used to detect mutation associated with resistance to treatment. It has also been shown that dynamic changes in ctDNA levels closely reflect changes in tumor burden. We prospectively monitored CTC and ctDNA early variations during first line chemotherapy for MBC.

Patients & methods: The French cohort COMET is a prospective study including first line HER2 negative patients (pts) receiving weekly paclitaxel and bevacizumab according to EMA approved combination. The aim of this cohort is to evaluate clinical, biological and radiological parameters associated with pts outcome (CTC, serum markers, ctDNA, pharmacogenomic polymorphisms, metabolomic parameters, visceral fat, serum estradiol level and quality of life). We present here the first planned analysis on pts evaluated for CTC (CellSearch) and ctDNA using targeted sequencing (Roche SeqCap technology) of a panel of 46 genes and 8 promoters, using unique molecular identifiers to increase ctDNA detection sensitivity. Blood samples were obtained at baseline (BL) and before the second cycle of chemotherapy (C2).

Results: From 09/2012 to 5/2014, 218 pts were included in this substudy. Median age was 55 years and 22% of pts had triple negative BC. At BL, 70% of pts had ≥1 detectable CTC per 7.5 ml of blood (median 4 CTC, range 1-30,000) and 37% at C2. With a threshold of ≥5 CTC, 47% of pts were positive at BL and 22% at C2. For ctDNA, out of the first 141 pts analyzed, 105 had at least one somatic mutation detected in plasma (74%). The average number of mutations per pt was 2.7 and most commonly mutated genes were TP53 and PIK3CA. ESR1 was found mutated in 9% of all cases and restricted to the ER+ subgroup. Median Allelic Frequency was 10% (range 0.6-83%). Only 33% of pts had detectable ctDNA at C2. At BL, CTC and ctDNA levels were correlated (r=0.46, p<0.0001). Despite no complete overlap, 11% of pts had no CTC nor ctDNA detected. Median follow-up was 53 months and median OS was 32 months. Increased level of CTC and ctDNA were significantly associated with decreased PFS and OS. At C2, ≥5 CTC or still detectable ctDNA were strong markers of reduced OS: HR 4.6 (CI95 3.1-7) and HR 3.2 (CI95 1.8–5.5), respectively (both p<0.0001). At multivariate analysis for PFS, detectable ctDNA at C2 and triple negative status were the only significant prognostic factors. None of serum marker level at BL or their early variations had prognostic value.

Conclusion: This is the largest prospective cohort assessing the respective prognostic values of early CTC and ctDNA changes in homogenously treated first line MBC patients. Analysis of mutations profile variations and comparison with primary tumor and metastasis biopsies are ongoing and may reveal early mechanisms of resistance.
Baseline circulating ESR1 mutation analysis in the randomised phase III EFECT study of fulvestrant versus exemestane in advanced hormone receptor positive breast cancer

Nicholas Turner¹, Claire Swift², Lucy Kilburn¹, Isaac Garcia-Murillas¹, Stephen Johnston², Aman Budzar³, John Robertson⁴, William Gradishar⁵, Martine Piccart⁶, Gaia Schiavon⁷ and Stepehen Chia⁸. ¹Institute of Cancer Research, London, United Kingdom; ²Royal Marsden Hospital, London, United Kingdom; ³MD Anderson Cancer Center, Houston; ⁴University of Nottingham, Nottingham, United Kingdom; ⁵Robert H. Lurie Comprehensive Cancer Center, Chicago; ⁶Institut Jules Bordet, Brussels, Belgium; ⁷Astra Zeneca, Cambridge, United Kingdom and ⁸British Columbia Cancer Agency, Vancouver, Canada.

Background. ESR1 mutations are acquired frequently in hormone receptor positive breast cancer after treatment with aromatase inhibitors (AI) in the metastatic setting. In prior analysis of the SoFEA phase III randomised trial, we demonstrated the detection of ESR1 mutations in circulating tumor DNA (ctDNA) predicted for greater benefit of fulvestrant compared to exemestane (Fribbens et al JCO 2016).

Methods. The phase III EFECT study randomised 693 patients with ER+ metastatic breast cancer who had progressed on a prior non-steroidal AI, between fulvestrant loading dose and then 250mg q28 days and exemestane (Chia S, et al. J Clin Oncol 2008). Baseline serum samples were available from 227 patients in EFECT, and were analysed for the 8 most common ESR1 mutations by multiplex digital PCR. The association between baseline ESR1 status and time to progression (TTP) was analysed using Kaplan-Meier methods.

Results. ESR1 mutations were successfully analysed in 98% (222/227) of patients with baseline serum samples, with ESR1 mutations detected in 23.4% (52/222) samples. Overall, detection of ESR1 mutations at baseline was associated with shorter TTP (hazard ratio [HR] 2.03, 95% CI 1.26-3.29, p=0.004). In patients with ESR1 mutation detected, TTP was 2.0 months (95%CI, 1.7-2.4) on exemestane and 3.5 months (95%CI, 1.9-5.0) on fulvestrant (HR 0.67, 95%CI 0.37-1.19, p=0.17). In patients without ESR1 mutations detected, TTP was 4.5 months (95%CI, 3.7-5.6) on exemestane and 3.7 months (95%CI, 3.3-5.2) on fulvestrant (HR 1.05, 95%CI 0.75-1.45, p=0.78). A meta-analysis of SoFEA and EFECT will be presented at the conference.

Conclusions. Historical serum samples may be used for ctDNA analysis, illustrating the potential for future research of sample archives. Patients with ESR1 mutation detected in ctDNA have poor outcome when treated with exemestane, replicating prior results from SoFEA and demonstrating clinical utility for ESR1 mutation ctDNA analysis.
Biomarker analysis by baseline circulating tumor DNA alterations in the MONALEESA-3 study

Patrick Neven¹, Katarina Petrakova², Giulia Val Bianchi³, Luis De la Cruz-Merino⁴, Guy Jerusalem⁵, Gabe S Sonke⁶, Arnd Nusch⁷, J Thaddeus Beck⁸, Stephen Chia⁹, Nadia Solovieff¹⁰, Karen Rodriguez Lorenc¹¹, Michelle Miller¹¹, Faye Su¹¹ and Seock-Ah Ln¹².

Background: In the Phase III MONALEESA-3 (NCT02422615) study, ribociclib (RIB; cyclin-dependent kinase 4/6 inhibitor) + fulvestrant (FUL) significantly prolonged progression-free survival (PFS) vs placebo (PBO) + FUL in postmenopausal women with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC). Here we present MONALEESA-3 efficacy data by molecular alterations detected in circulating tumor DNA (ctDNA) at baseline.

Methods: Postmenopausal women (N=726) with HR+, HER2– ABC (treatment naïve or received ≤1 line of prior endocrine therapy for ABC) were randomized 2:1 to RIB or PBO (600 mg/day; 3-weeks-on/1-week-off) + FUL (500 mg per label). Biomarker analysis of baseline ctDNA was an exploratory endpoint. Baseline plasma samples were collected from 692 patients (pts), and plasma ctDNA was analyzed using next-generation sequencing with a targeted panel of ~550 genes. The subgroup analysis was performed in 600 pts (RIB + FUL n=400; PBO + FUL n=200) with evaluable ctDNA data. Results were not adjusted for multiple testing.

Results: Alterations (frequency) were observed in the following genes: PIK3CA (35%), ESR1 (14%), TP53 (18%), CDH1 (12%), FGFR1 (5%), FGFR1/ZNF703/WHSC1L1 (11%), cell cycle-related (CCC) genes (16%), and genes involved in receptor tyrosine kinase (RTK) signaling (20%), and the mitogen-activated protein kinase (MAPK) pathway (10%). PFS hazard ratios favored RIB vs PBO regardless of baseline ctDNA gene alteration status (Table).

</table>

Numerically shorter PFS was observed in pts with altered vs wildtype (WT) genes, irrespective of treatment. A slight trend towards limited RIB benefit vs PBO was observed in pts with altered CCC and RTK genes. RIB benefit was more pronounced vs PBO in pts with altered CDH1 and MAPK genes. PIK3CA and ESR1 analyses for pts receiving treatment in the first- or second-line setting will be presented at the meeting.

**Conclusions:** Generally consistent PFS benefit for RIB + FUL vs PBO + FUL was observed irrespective of baseline ctDNA alterations; altered status trended to correlate with a shorter PFS. Results are hypothesis generating and should be interpreted with caution for some subgroups due to small sample sizes.
Circulating ESR1 mutation detection rate and early decrease under first line aromatase inhibitor and palbociclib in the PADA-1 trial (UCBG-GINECO)

**Background:** Palbociclib (Pal) combined with an aromatase inhibitor (AI) is a standard of care as first line therapy in ER+ HER2-metastatic breast cancer (MBC). While ESR1 mutations (ESR1Mut) are a characterized mechanism of resistance to AI as single agent, it remains unknown how these mutations, when detected prior to treatment initiation, may affect the efficacy of Pal+AI. In a subsidiary analysis of the first line PADA-1 trial, we report the ESR1Mut detection rate at baseline and, in patients with ESR1Mut detected at baseline, how ESR1 circulating tumor DNA levels changed after the first cycle of Pal+AI therapy.

**Methods:** PADA-1 (NCT03079011) is a randomized phase III trial testing the clinical utility of real time ESR1Mut detection (baseline, at 1 month and then every 2 months) in the blood of patients treated with Pal+AI (first step). Patients with rising ESR1Mut in circulating tumor DNA (i.e. increasing or appearing mutations during first line Al-Pal therapy) are randomized in a second step between keeping Al-Pal or switching to Fulvestrant-Pal. Main inclusion criteria are patients with ER+ HER2- MBC, who never received adjuvant AI or completed adjuvant AI for >12 months, with neither prior therapy for MBC nor visceral crisis. ESR1Mut are tracked in circulating DNA from up to 4ml of plasma by a ddPCR-based assay targeting E380, L536, Y537 and D538 hotspots (i.e. #90% of known ESR1 activating mutations) with #0.1% sensitivity (Bidard et al, AACR 2018 #3867).

**Results:** From 04/2017 to 05/2018, 803 MBC patients have been included in 80 centers. Among these patients, ESR1Mut were detected at baseline, prior to any systemic therapy, in 17 patients (2.1%, 95%CI=[1.3;3.3%]). ESR1Mut levels ranged from 6 to 3959 copies/ml of plasma (median: 30 copies/ml); allelic frequency ranged from 0.3% to 47% (median=3.5%). ESR1Mut were not associated with any of the tumor pathological characteristics (including PR status, primary TNM stage, number and type of metastatic sites); a non-significant association was observed with primary tumor grade (1.7% vs 4.1% in grade I-II vs III, Fisher: p=0.15). Among patients who received a prior adjuvant endocrine therapy, ESR1Mut detection rate was lower in patients treated with tamoxifen (0.9% with any tamoxifen exposure vs 5.7% with no tamoxifen exposure; Yates Chi2: p=0.01) and observed only in patients treated with AI (4.9% with any AI exposure vs 0% with no AI exposure, Yates Chi2: p=0.009). Among the 17 patients with ESR1Mut detected at baseline, only 4 patients had residual detectable ESR1Mut detected after 1 month of Al-Pal therapy (3 of these 4 had decreased levels of ESR1 mutation).

**Conclusion:** ESR1Mut is a rare event in untreated AI-sensitive, ER+ HER2- MBC patients. Such detection is primarily associated with prior use of AI in the adjuvant setting. Interestingly, in most MBC patients with ESR1Mut detected at baseline, ESR1Mut became undetectable after 1 month of Al-Pal therapy, suggesting that this combination may retain early antitumor efficacy.

**Funding:** Pfizer
mRNA signatures predict response to durvalumab therapy in triple negative breast cancer (TNBC)—Results of the translational biomarker programme of the neoadjuvant double-blind placebo controlled GeparNuevo trial

1German Breast Group, Neu-Isenburg, Germany; 2Institut für Pathologie, Charité-Universitätsmedizin, Berlin, Germany; 3Klinik für Frauenheilkunde und Geburtshilfe, Universitätsklinikum, Frankfurt, Germany; 4HELIOS Klinikum, Berlin-Buch, Germany; 5Allgemeine Pathologie, Universitätsklinikum, Heidelberg, Germany; 6Klinikum zum Roten Kreuz, München, Germany; 7Brustzentrum, Universitätsklinikum, Erlangen, Germany; 8Universitätsfrauenklinik, Brustzentrum, Ulm, Germany; 9SRH Wald-Klinikum, Gera, Germany; 10Sana Klinikum, Offenbach, Germany; 11Praxisklinik für Hämatologie und Onkologie, Koblenz, Germany; 12Brustzentrum, Charité-Universitätsmedizin, Berlin, Germany; 13Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany and 14Zentrum Familiärer Brust- und Eierstockkrebs, Universitätsklinikum, Köln, Germany.

Background: The GeparNuevo trial showed a numerical increase in the pCR rate to 53% vs 44%; p=0.281 compared to placebo in TNBC with the addition of the anti-PD-L1 antibody durvalumab to a neoadjuvant anthracycline-taxane containing chemotherapy (Loibl S et al. ASCO 2018). In a predefined subgroup analysis, a significant increase of the pCR rate was observed for patients that received durvalumab for 2 weeks alone prior to the start of chemotherapy in a window phase (61% vs 41%, pinteraction=0.048), while the pCR rate was not increased for the subset of patients that did start durvalumab together with chemotherapy.

Here we report the main results of the translational programme for GeparNuevo with a focus on mRNA signatures predictive for pCR in pretherapeutic core biopsies.

Methods: A total of 162 baseline FFPE core biopsies were evaluable for expression of 2560 genes using the HTG EdgeSeq® system that combines a modified nuclease protection assay with next generation sequencing. Data was processed as recommended by the HTG and median transformed for further analyses. For differential gene expression analyses, the data was scale-normalized (TMM normalization; EdgeR package) and linear models were fit (limma package). Prior to these analyses, genes were filtered based on minimal expression (> 4) and variability (IQR > 1). As a first step, predefined immune-genes signature (TILs signature) (Denkert et al. JCO 2016) as well as IFN-gamma signatures were evaluated for correlation with pCR in logistic regression models. Subsequently, we performed a differential gene expression analysis according to therapy response for the durvalumab-arm and the placebo arm using the pre-filtered candidate genes. Gene names are not included in this abstract to allow filing of IP, but full gene names will be presented at the SABCS meeting.

Results: The predefined TIL- and IFN-gamma signatures were associated with increased pCR rates in the complete cohort (TIL-signature: OR 1.44, 95% CI 1.15-1.82, p=0.002; IFN-Gamma-signature: OR 1.63, 95% CI 1.22-2.24, p=0.002) as well as in the durvalumab arm (p=0.012 and 0.042) and the placebo arm (p=0.050 and 0.011). These signatures were general pCR predictors without specificity for durvalumab response.

Additional 44 genes were significantly (p<0.05) correlated with pCR in the durvalumab arm. Of those, 21 genes were upregulated and 23 genes were downregulated in pCR patients. 14 of the 21 upregulated genes are related to tumourbiologically relevant immune cell functions. A total of 6 of the 44 genes had a positive test for interaction (interaction p<0.05) with the therapy arm (durvalumab + NACT vs. placebo + NACT), suggesting that these genes might specifically predict response to durvalumab. Additional analyses investigating the role of molecular tumor subtypes, additional immune gene signatures and other subgroup analyses will be presented at the meeting.

Conclusion: Our results show that specific immune-related gene expression signatures predict response to durvalumab in primary triple negative breast cancer.

The trial was financially supported by Astra Zeneca and Celgene
Ribociclib with endocrine therapy for premenopausal patients with hormone receptor-positive, HER2-negative advanced breast cancer: Biomarker analyses from the phase III randomized MONALEESA-7 trial

Aditya Bardia¹, Marco Colleoni², Saul Campos-Gomez³, Kyung Hae Jung⁴, Paul Wheatley-Price⁵, Sherko Kümmel⁶, Vichien Srimuninnimit⁷, Donatienne Taylor⁸, Young-Hyuck Im⁹, Gareth Hughes¹⁰, Ivan Diaz-Padilla¹⁰, Michelle Miller¹¹, Faye Su¹¹, and Debu Tripathy¹².

¹Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston; ²Istituto Europeo di Oncologia, Milan, Italy; ³Centro Oncológico Estatal, Instituto de Seguridad Social del Estado de México y Municipios, Toluca, Mexico; ⁴Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; ⁵University of Ottawa, Ottawa, Canada; ⁶Breast Unit, Kliniken Essen-Mitte, Essen, Germany; ⁷Siriraj Hospital, Mahidol University, Bangkok, Thailand; ⁸CHU UCL Namur – Site de Sainte-Elisabeth, Namur, Belgium; ⁹Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; ¹⁰Novartis Pharma AG, Basel, Switzerland; ¹¹Novartis Pharmaceuticals Corporation, East Hanover; and ¹²The University of Texas MD Anderson Cancer Center, Houston.

Background: In the MONALEESA-7 study (NCT02278120), ribociclib (RIB) + a non-steroidal aromatase inhibitor (NSAI)/tamoxifen (TAM) + goserelin (GOS) significantly improved progression-free survival (PFS) vs placebo (PBO) + NSAI/TAM + GOS in premenopausal patients (pts) with hormone receptor-positive (HR+), HER2-negative (HER2–) advanced breast cancer (ABC; hazard ratio 0.553; 95% confidence interval [CI] 0.441–0.694; p=0.0000000983). Here we present PFS data by baseline (prior to study treatment) tumor (primary and metastatic) Ki67, total Rb, and p16 protein expression, and CCND1 (cyclin D1), CDKN2A (p16), and ESR1 (estrogen receptor) messenger RNA (mRNA) levels.

Methods: Pre-/perimenopausal pts (N=672; ≤1 line of prior chemotherapy and no prior endocrine therapy for ABC) were randomized 1:1 to either RIB (600 mg/day; 3-weeks-on/1-week-off) or PBO + an NSAI (letrozole [2.5 mg/day]/anastrozole [1 mg/day]) or TAM (20 mg/day) + GOS (3.6 mg every 28 days). The primary endpoint was local PFS, while correlation with biomarker expression was an exploratory endpoint. Baseline tumor tissue was evaluated for Ki67, total Rb, and p16 protein expression by immunohistochemistry and CCND1, CDKN2A, and ESR1 gene expression by NanoString® nCounter. To assess correlations between protein/gene expression and PFS, pts were classified into prespecified low vs high expression subgroups; 14% of positively stained cells was used as a cutoff for Ki67, 10th percentile was used as a cutoff for total Rb, and median expression was used as a cutoff for all other proteins/genes.

Results: Based on a data cutoff of August 20, 2017, PFS hazard ratios for most biomarker subgroups favored RIB + NSAI/TAM + GOS vs PBO + NSAI/TAM + GOS (Table).

Table
It is difficult to draw conclusions for total Rb protein expression due to the small sample size and limited number of events. RIB treatment benefit was numerically greater in pts with high vs low CCND1 mRNA expression levels.

Conclusions: Generally consistent PFS benefits with RIB + NSAI/TAM + GOS vs PBO + NSAI/TAM + GOS were observed irrespective of baseline biomarker expression in cell cycle- and proliferation-related genes. Updated results will be presented at the meeting.
High-throughput phosphoproteomics (HTPS) in neoadjuvant (NEO) breast cancer (BC) reveals clusters of extreme sensitivity to paclitaxel (T)

Miguel Quintela-Fandino¹, Ana Lluch², Luis Manso³, Isabel Calvo⁴, Javier Cortes⁵, Jose A Garcia-Saenz⁶, Ivana Zagorac¹, Paula Tapial-Martinez¹, Gonzalo Gomez-Lopez¹, Coral Fustero¹, Javier Muñoz¹, Lucía Gonzalez-Cortijo⁷ and Silvana Mouron¹. ¹CNIO - Spanish National Cancer Research Center, Madrid, Spain; ²Hospital Clinico Universitario de Valencia, Valencia, Spain; ³Hospital 12 de Octubre, Madrid, Spain; ⁴MD Anderson Madrid, Madrid, Spain; ⁵VHIO - Vall d'Hebron Institute of Oncology, Barcelona, Spain; ⁶Hospital Clinico San Carlos, Madrid, Spain and ⁷Hospital Universitario Quiron, Madrid, Spain.

Background: NGS has elucidated the mutational landscape in BC. However, the correlation between mutational landscapes and complex phenotypic traits such as drug response is yet unclear. The genomic and transcriptomic aberrations coalesce into a diverse number of phosphorylation-driven patterns of activation of the proteome. These patterns are and associated to clinical outcomes of interest. The specific nature of the phosphopeptides in a profile versus another can be driven by a small number of activated kinases. In the past we relied on mass-spectrometry-based HTPS to build a kinase-based classification of triple-negative breast cancer (TNBC, Nat. Comms, in press), which is more parsimonious than gene-centered classifications and uncovers new actionable targets. We implemented this methodology to find predictors of response to T in early BC.

Methods: Training set: fresh baseline and day+15 tumor biopsies form a trial in NEO HER2-negative BC (N=139) that randomized patients to T (80 mg/m² weekly x12) plus placebo or nintedanib (150 mg b.i.d) were processed with a hybrid ion trap-orbitrap mass spectrometer after TiO2 phospho-enrichment. Phosphoprofiles were compared pair-wise according to the following factors: day 0 versus day + 15, standard versus experimental arm, pathologic response Symmans/Pusztai (Symmans) 0/1 vs 2/3. Kinases driving each phosphoprofile were solved by an in silico algorithm termed kinase-set enrichment analysis (KSEAS).

Validation set: an in-house designed and previously validated mass-spectrometry-to-immunohistochemistry translation algorithm was used to validate the kinases enriched in the profiles from the baseline samples of patients achieving Symmans 0/1 (pCR) or Symmans=3 in the training set. Probes against those kinases were validated in an independent dataset of 160 HER2-negative patients receiving NEO T followed by AC. H-score of each activated kinase was divided in quartiles (Q1 to Q4), and upper-quartiles (Q1) of each kinase were tested in a multivariate logistic regression model to predict pCR adjusted by T, N, age, G, ER/PR and Ki67.

Results: >2.5 millions of spectra were captured, identifying >35000 unique phosphopeptides mapping to >2500 unique proteins per sample. Training set: KSEAS revealed that a high activity of CDK4 and pP70S6K drove the baseline phosphoprofiles of the patients obtaining pCR in the T arm, whereas pSTAT3, pSrc and BARD drove that of the patients achieving Symmans= 3. In the validation set, H-score cut-offs for Q1 were 1.21, 0.69, 0.79, 1.64 and 1.54 for pP70S6K, CDK4, pSTAT3, pSrc and BARD. TNBC patients with Q1 pP70S6K or Q1 CDK4 achieved pCR in 100% of the cases (versus 45% in Q2-4). In the HR+ cases, the pCR rate for Q1 patients was 50% and 61% respectively. In the multivariate model (all patients), having Q1 pP70S6K or CDK4 multiplied by 2.3- and 3.6-fold, respectively, the probability of achieving pCR (P<0.05). Regarding Symmans=3, BARD and pSTAT3 lost significance in the validation but not pSrc (2.5-fold less probability of pCR, P<0.005).

Conclusions: HTPS is a useful tool to find associations with complex traits. TNBC and HR+ patients with high pP70S6K or CDK4 receiving NEO T-based chemotherapy achieve very high rates of pCR.
Treatment with abemaciclib modulates the immune response in gene expression analysis of the neoMONARCH neoadjuvant study of abemaciclib in postmenopausal women with HR+, HER2 negative breast cancer

Sara Hurvitz¹, Miguel Martin², Michael Press³, Sameera Wijayawardana⁴, Manisha Brahmachary⁴, Philip J Ebert⁴, Suzanne Young⁴, Valerie Jansen⁴ and Dennis Slamon¹. ¹University of California, Los Angeles, CA; ²Hospital General Universitario Gregorio Marañón, Madrid, Spain; ³University of Southern California, Los Angeles and ⁴Eli Lilly and Company, Indianapolis.

Background: Abemaciclib is a selective inhibitor of CDK4 & 6 approved on a continuous dosing schedule for the treatment of HR+, HER2- metastatic breast cancer (MBC) patients (pts) in combination with endocrine therapy or as monotherapy. Recent studies have demonstrated the potential for CDK4 & 6 inhibitors, including abemaciclib, to promote anti-tumor immunity. Schaer et al., (Cell Reports 2018) showed that abemaciclib monotherapy results in upregulation of antigen presentation on tumor cells and increases T-cell activation. These activities synergized with anti-PD-L1 therapy to further enhance immune activation leading to complete tumor rejection in murine tumor models (Schaer et al., Cell Reports 2018). In this exploratory analysis, we evaluated the early and late immune-modulating effects of abemaciclib in the neoadjuvant study neoMONARCH (NCT02441946).

Methods: NeoMONARCH is a Phase II trial in women with stage I-IIIB HR+, HER2- BC evaluating neoadjuvant treatment with 2 weeks of abemaciclib, alone or in combination with anastrozole (abemaciclib+ANZ), or ANZ alone. All patients received 14 weeks of abemaciclib +ANZ after the first 2 weeks of treatment. Serial biopsies were collected at 3 time points: Baseline (BL) - prior to treatment, Early - after 2 weeks of therapy with abemaciclib, ANZ, or abemaciclib+ANZ, and Late – after 2 weeks of initial therapy followed by 14 weeks of abemaciclib+ANZ. RNA was extracted from formalin fixed paraffin embedded (FFPE) tumor biopsies at each time point and subjected to whole transcriptome RNA sequencing. The curated data were subjected to statistical analysis using ANOVA tests followed by pathway analysis using Ingenuity Pathway Analysis (IPA) and Gene Set Enrichment Analysis (GSEA).

Results: Consistent with the known activity of abemaciclib to inhibit the cell cycle, we observed at the early and late time points a significant treatment induced downregulation of genes related to mitotic spindle organization, replication stress response, G2M checkpoint, and E2F targets. Abemaciclib treatment for 2 weeks, alone or in combination with ANZ, followed by 14 weeks of combination therapy was associated with upregulation of gene expression signatures related to T-cell immune response and antigen presentation. Importantly, this phenomenon was not observed with 2 weeks of ANZ treatment alone followed by 14 weeks of combination therapy.

Conclusion: These data lend support that continuous inhibition of CDK4 & 6 signaling by abemaciclib treatment leads to prolonged cell cycle arrest resulting in tumor cell apoptosis & senescence, which then leads to an enhanced immune activation.
Ki-67 (30-9) scoring and differentiation in Luminal A and Luminal B breast cancer subtypes

Giuseppe Viale1,2, Amy E Hanlon Newell3, Espen Walker3, Isaac Bai3, Lella Russo1, Patrick Dell’Orto1 and Patrick Maisonneuve4.
1European Institute of Oncology, Milan, Italy; 2University of Milan, School of Medicine, Milan, Italy; 3Ventana Medical Systems, Inc., Tucson, AZ and 4European Institute o Oncology, Milan, Italy.

Introduction
Ki-67 labeling index is a powerful prognostic marker in breast cancer (BC). It is especially useful in assessing the risk of recurrence for estrogen receptor-positive (ER+) BC, where it may be considered a surrogate of the molecular assays for distinguishing Luminal A-like from Luminal B-like BCs. We evaluated the performance of the VENTANA anti Ki-67 (30-9) rabbit monoclonal antibody in assessing the risk of distant relapses for a large series of patients with ER+ BC treated and followed up in a single Institution.

Patients and Methods
The initial cohort (9415 patients) comprised all women operated on for early ER+, HER2-negative (HER2-) BC at the European Institute of Oncology (IEO), who did not receive neo-adjuvant treatment1. We subsequently restricted the cohort to 3986 patients operated on between 1998-2002 and for whom long-term follow-up data was available. A case-cohort was built by randomly selecting 17% of the above cohort (679 patients, including 84 with events). Additional 303 patients who developed an event (metastasis in distant organs or death due to BC as primary events) were added to this cohort. Ki-67 was evaluated using the anti-Ki-67 (30-9) antibody (Ventana Medical Systems, Inc., Tucson, AZ) using OptiView IHC DAB detection on the BenchMark ULTRA advanced staining platform. The stained slides were evaluated using the scoring method described by the International Ki-67 in BC Working Group.

We considered “Luminal A-like” tumors that were ER+, HER2-, with Ki-67 <14% or with Ki-67 14-19% and PgR ≥20%, and “Luminal B-like” ER+, HER2- tumors with Ki-67 14-19% and PgR <20% or with Ki-67 ≥20%

The main outcome was distant disease-free survival (DDFS) and was calculated from the date of surgery to the date of any first event or last contact with the patient.

Cumulative incidence curves were drawn for patients in the sub-cohort and differences between BC subtypes were assessed using the log-rank test. Multivariable Cox regression with inverse sub-cohort sampling probability weighting was used to evaluate the risk of metastasis or death from BC across groups.

Results
In the sub-cohort, 400 (58.9%) patients had “luminal A-like” and 279 (41.1%) “luminal B-like” BC. The 10-year cumulative incidence of distant metastasis (or BC related death as first event) in the two groups were respectively 8.2% and 24.5% (log rank P<0.0001)

In the whole case-cohort, multivariable analysis confirmed statistically significant increased risk of events for women with “Luminal B-Like” BC compared to women with “Luminal A-Like “BC (HR=1.97; 95% CI 1.38-2.79), after adjustment for pT, pN, PVI and menopausal status.

Conclusion
Ki-67 evaluated using the VENTANA anti-Ki67 (30-9) antibody, was able to stratify patients with endocrine responsive BC, maximizing the number of those classified as having ‘Luminal A-like’ intrinsic subtype for whom the use of cytotoxic drugs could be at large avoided.

Palbociclib in combination with fulvestrant or tamoxifen as treatment for hormone receptor positive (HR+) metastatic breast cancer (MBC) with prior chemotherapy for advanced disease (TBCRC 035) A phase II study with pharmacodynamics markers

Hope S Rugo¹, Erica L Mayer², Anna Marie Storniolo³, Claudine Isaacs⁴, Ingrid Mayer⁵, Vered Stearns⁶, Rita Nanda⁷, Julie Nangia⁸, Chiara Wabl¹, Amy Deluca¹, Bose Kochupurakkal², Antonio C Wolff⁶ and Geoff I Shapiro². ¹University of California San Francisco Comprehensive Cancer Center, San Francisco; ²Dana-Farber/ Harvard Cancer Center, Boston; ³Indiana University, Indianapolis; ⁴Georgetown University, Washington; ⁵Vanderbilt University, Nashville; ⁶Johns Hopkins University, Baltimore; ⁷University of Chicago, Chicago and ⁸Baylor College of Medicine, Houston.

Background
Addition of the cyclin dependent kinase 4/6 inhibitor (CDK4/6i) palbociclib to endocrine therapy in the first and later line settings significantly improves progression free survival (PFS) in patients with HR+ MBC. The primary toxicity is neutropenia without an increase in febrile neutropenia. TBCRC035 explored rates of neutropenia in patients who had received prior chemotherapy for MBC with 2 dose levels of palbociclib, and correlated changes in retinoblastoma protein phosphorylation (pRB) and Ki67 expression in proliferating keratinocytes and tumor with response.

Methods
TBCRC035 is a 1:1 randomized multicenter phase II study evaluating palbociclib at either 125 or 100 mg in combination with physician choice fulvestrant or tamoxifen. Eligible patients (pts) with HR+ MBC had received >1 but ≤3 lines of chemotherapy for MBC, any number of prior hormone therapies, and were naïve to CDK4/6i. The primary endpoint was grade 3/4 neutropenia; secondary endpoints included response, safety/tolerability, inhibition of pRB and change in Ki67 in skin and tumor at day 14-21 of treatment compared to baseline. FFPE sections of skin punch and tumor biopsies obtained before and on treatment were stained using antibodies to Ki67, total RB, and phospho-RB-S780 using BOND polymer red detection. Stained slides were scanned into the Aperio image analysis platform; the percentage of marker positive cells and H-score was determined.

Results
70 pts were enrolled (fully accrued); 35 randomized to 100 vs 125 mg of palbociclib respectively; data for the last 3 pts on the 125 mg arm is pending. Grade 3/4 neutropenia was more common in the 125 mg vs the 100 mg arm (56 vs 34%); dose adjustments for adverse events (AEs) occurred in 47 vs 43%, 4 vs 0 pts discontinued treatment due to AEs. Grade 3 febrile neutropenia was rare (1 patient each arm). Median duration of treatment was 5.2 vs 7.2 months. Response data and correlation with changes in pRB and Ki67 expression in skin and tumor by treatment arm will be reported.

Conclusion
In pts with prior chemotherapy for HR+ MBC, treatment with 100 mg of palbociclib in patients is associated with a lower rate of ≥ grade 3 neutropenia compared to 125 mg. Correlation of response by dose with pRB and Ki67 has the potential to inform palbociclib dosing and reduce toxicity for pts with HR+ MBC.
Results from KATE2, a randomized phase 2 study of atezolizumab (atezo)+trastuzumab emtansine (T-DM1) vs placebo (pbo)+T-DM1 in previously treated HER2+ advanced breast cancer (BC)

Background
T-DM1 has improved PFS and OS in HER2+ advanced BC patients (pts) who previously progressed on trastuzumab and a taxane (Verma NEJM 2012). Preclinical data show that atezo (anti–PD-L1) inhibits PD-L1 binding to PD-1 and B7.1 to restore antitumor immunity. PD-L1 is often expressed on tumor-infiltrating immune cells (IC) in BC. KATE2 (NCT02924883) is the first study to assess atezo combined with T-DM1 in previously treated HER2+ advanced BC.

Method
Eligible pts had HER2+ advanced BC previously treated with trastuzumab and a taxane and progressed on treatment for metastatic disease or within 6 mo of adjuvant therapy. Pts were randomized 2:1 to atezo 1200 mg or pbo+T-DM1 3.6 mg/kg IV q3w (crossover not permitted). The primary endpoint was investigator-assessed PFS per RECIST v1.1. Additional endpoints included OS, ORR, DoR (secondary), PFS in the PD-L1+ subgroup (exploratory) and safety. Data cutoff: 11 Dec 2017.

Result
133 pts were randomized to atezo+T-DM1 and 69 pts to pbo+T-DM1. 49% and 46% received prior pertuzumab for metastatic BC; median duration of pertuzumab treatment was 10 and 13 mo, respectively. Median follow-up was 8.5 and 8.4 mo, respectively. Efficacy in the ITT population and biomarker subgroups are shown.

aORR-evaluable pts (measurable disease at baseline): n=132 in atezo+T-DM1 arm. PD-L1+, IC1/2/3; PD-L1−, IC0; measured per the VENTANA SP142 IHC assay. cPost hoc exploratory analyses.

PFS HR was 0.82 (95% CI: 0.55, 1.23); p=0.3332. At data cutoff, 13 OS events (10%) in the atezo+T-DM1 arm and 8 (12%) in the pbo+T-DM1 arm had occurred. mDoR was not reached. 44% and 41% of safety-evaluable pts had an AE of Gr ≥3 with atezo+T-DM1 and pbo+T-DM1, respectively. The most common was thrombocytopenia (13% and 4%). The incidence of serious AEs (SAEs) was 33% with atezo+T-DM1 and 19% with pbo+T-DM1, with the most common being Gr 1-2 pyrexia with atezo+T-DM1 (5%) and abdominal pain (3%) and seizure (3%) with pbo+T-DM1. AE rates leading to atezo/pbo or T-DM1 discontinuation were 25% and 15%, respectively, with atezo+T-DM1 and 15% and 13% with pbo+T-DM1. 1 patient in the atezo+T-DM1 arm had a drug-related Gr 5 AE (hemophagocytic syndrome).

Conclusion
Atezo+T-DM1 did not demonstrate a clinically significant PFS benefit vs pbo+T-DM1; OS and DoR data are not yet mature. Numerically higher PFS and ORR were seen with atezo+T-DM1 in PD-L1+ pts. T-DM1 safety in both arms was consistent with its known profile. Although the combination of atezo+T-DM1 showed a numerically higher incidence of SAEs and discontinuation of atezo due to an AE, rates of Gr 3-5 AEs were similar between arms. Additional biomarker data, including gene expression and mutation data, will be presented.
Incidence of late relapse in HER2-positive (HER2+) breast cancer patients receiving adjuvant trastuzumab: Combined analysis of NCCTG (Alliance) N9831 and NSABP (NRG) B31

Saranya Chumsri1, Zhuo Li2, Daniel J Serie2, Afshin Mashadi-Hossein3, Gerardo Colon-Otero1, Nan Song4, Katherine Pogue-Geile4, Patrick Gavin4, Soonmyung Paik4, Alvaro Moreno-Aspilta1, Edith A Perez1 and E Aubrey Thompson5.

1Division of Hematology and Medical Oncology, Jacksonville, FL; 2Division of Biomedical Statistics and Informatics, Jacksonville, FL; 3NanoString Inc., Seattle, WA; 4National Surgical Adjuvant Breast and Bowel Project (now NRG Oncology), PA, Pittsburg, PA and 5Department of Cancer Biology, Jacksonville, FL.

Background: Recent trials showed potential benefit of extended adjuvant endocrine therapy and relatively high risk of relapse after 5 years (yr) in hormone receptor-positive (HR+) HER2- breast cancer. While risk of late relapse in HR+ HER2- is fairly well defined, the risk of late relapse in HER2+ remains largely unknown. **Method:** 4547 HER2+ patients treated with adjuvant chemotherapy alone or combined with trastuzumab (TH) were included (3132 from North Central Cancer Treatment Group [NCCTG, now Alliance] N9831; 1415 from National Surgical Adjuvant Breast and Bowel Project [NSABP, now NRG] B-31). Intrinsic subtypes were assessed by Prosigna test. Kaplan-Meier method and Cox proportional hazards model were used for analysis. **Results:** Median follow-up was 10.4 yr in N9831 and 7.0 yr in NSABP-B31. 54.5% of pts had HR+ disease. Pts were classified as HER2 enriched (77.4%), Luminal B (10.1%), Luminal A (7.7%), and Basal (4.8%). In multivariate Cox regression analysis in both treatment groups, HR+ was significantly associated with improved recurrence-free survival (RFS) during the first 5 yr (HR 0.65, 95% CI 0.56-0.77, p<0.001) but there was no significant difference during yr 5-10 (HR 1.32, 95% CI 0.93-1.88, p=0.12). In HR+HER2+ pts treated with TH, cumulative hazard for relapse or death was lower in the first 5 yr (10.96%, 95%CI 8.78-13.08) compared to HR-HER2+ (17.48%, 95%CI 14.59-20.27), with adjusted HR 0.60 (95% CI: 0.45-0.79, p<0.001). Unlike HR+HER2- disease, cumulative hazard of relapse or death in yr 5-10 in HR+HER2+ pts treated with TH was lower at 8.6% (95%CI 6.16-10.97). This is slightly higher than pts with HR-HER2+ at 5.75% (95% CI 3.18-8.24, adjusted HR=1.7, 95%CI 1.01-2.85, p=0.046). Compared to 22% and 31% risk of relapse after 5 yr in N0 and N1 HR+HER2- in recent publication, 3.23% (95%CI 0-9.25) of pts with HR+HER2+ with N0 developed recurrence in yr 5-10 and 6.39% (95%CI 3.09-9.59) in those with N1 disease. Albeit rare, pts with Luminal A tumors had 89.8% relapse-free survival at 10 yr compared to Luminal B 82.3%, HER2 enriched 76.8%, and Basal 74.19%. **Conclusions:** Even without extended adjuvant endocrine therapy in both trials, risk of late relapse in HR+ HER2+ appeared to be low, particularly in pts with no lymph node involvement, may not outweigh side effects of continuing endocrine therapy beyond 5 yr.

Background: CDK4/6 inhibition combined with anti-HER2 therapy is currently being explored in HER2-positive (HER2+) BC. Here, we report the efficacy, safety and genomic analysis of STAGE 1 of the PATRICIA phase II trial evaluating palbociclib in combination with trastuzumab (TTZ) in advanced HER2+ BC.

Methods: PATRICIA is an exploratory, prospective, open-label, multicenter phase II trial. Patients (pts) had received 2-4 prior lines of anti-HER2-based regimens. Treatment consisted of TTZ 6 mg/kg every 3w and palbociclib 200 mg daily for 2w and 1w off. The study was based on a Simon 2-stage design comprising 3 cohorts: estrogen receptor (ER)-negative (cohort A), ER+ (cohort B1) and ER+ with letrozole (cohort B2). Pts ER+ were randomized to cohorts B1 or B2. The trial included a safety run-in phase of the first 12 pts. For part 1 to be successful, at least 6 pts of 15 had to be progression-free at 6 months (PFS6R of 40%) in each cohort. Secondary objectives included safety and the association of the research-based PAM50 intrinsic subtyping with PFS. PAM50 was performed from FFPE samples using the nCounter platform. Multivariable Cox regression analyses evaluating PAM50 subtypes, age, performance status, treatment line, type of biopsy and endocrine treatment were performed.

Results: A total of 45 pts were recruited (n=15 in each cohort). Median age was 59.5y, and median number of prior lines was 3.0. The PFS6R in cohorts A, B1 and B2 were 33.3% (5/15), 40.0% (6/15) and 53.3% (8/15), respectively. Regarding safety, grade 1-2 and 3-4 toxicities occurred in 97.7% and 84.4% of pts. The most common grade 3-4 toxicities were neutropenia (80%) and thrombocytopenia (17%). Dose reductions were required in 60% of pts. Regarding PAM50, a total of 40 (83.9%) tumors samples (22 primary and 18 metastasis) were profiled. Subtype distribution was as follows: 92.9% HER2-enriched (HER2-E) and 7.1% Basal-like in cohort A, and 46.2% HER2-E, 23.1% Luminal B, 19.2% Luminal A and 11.5% Normal-like in cohorts B1+B2. No significant differences in PFS were observed across the 3 cohorts. In cohorts A+B+1+B2, Luminal disease defined by PAM50 showed a higher median PFS compared to non-luminal disease (12.4 vs. 4.1 months; adjusted hazard ratio=0.37; p-value=0.052). Clinical Benefit Rate (CBR6) was 73% in Luminal Vs. 31% in non-luminals (p=0.031). In cohorts B1+B2, Luminal disease defined by PAM50 showed a higher median PFS compared to non-luminal disease (12.4 vs. 4.1 months; adjusted hazard ratio=0.30; p-value=0.025). CBR6 was 73% in Luminal Vs. 25% in non-luminals (p=0.022). No clinical-pathological variable was found associated with PFS or CBR6 in all pts or in cohorts B1+B2.

Conclusion: Palbociclib in combination with TTZ is safe and active in TTZ pre-treated HER2+ advanced BC, specially within ER+ disease. Identification of the non-luminal subtypes by PAM50 might help identify pts who might not derive a large benefit from this treatment strategy regardless ER status. Our results might have important implications for current and future clinical trials evaluating CDK4/6 inhibitors in HER2+ disease. In Part 2, a total of 92 pts in cohorts B1 and B2 will be included to better assess the efficacy of this treatment strategy.
Analysis of ERBB2 (HER2) amplification by ctDNA in a phase Ib dose-escalation trial evaluating trastuzumab emtansine (T-DM1) with neratinib in women with metastatic disease with initially diagnosed HER2+ breast cancer: NSABP FB-10

Jame Abraham1,2, Shannon L Puhalla1,3, William M Sikov1,4, Alberto J Montero1,2, Mohamad A Salkeni1,5, Wajeeda A Razaq1,6, Jan H Beumer1,7, Brian F Kiesel1,7, Marc E Buyse8, Laura M Adamson1, Ashok Srinivasan1, Katherine L Pogue-Geile9, Carmen J Allegra10, Rebecca J Nagy11 and Samuel A Jacobs1,2. 1NSABP Foundation, Pittsburgh; 2Cleveland Clinic Foundation, Cleveland; 3University of Pittsburgh Medical Center, Pittsburgh; 4Women and Infants Hospital of RI, Providence; 5West Virginia University, Morgantown; 6Peggy and Charles Stephenson Oklahoma Ctr, Oklahoma City; 7UPMC Hillman Cancer Center, Pittsburgh; 8IDDI, Inc., San Francisco; 9NSABP/NRG Oncology, Pittsburgh; 10University of Florida, Gainesville; 11Guardant Health, Redwood City and 12University of Pittsburgh Cancer Institute, Univ of Pgh School of Medicine, Pittsburgh.

Background:
In this phase Ib study, the activity of T-DM1 plus N was assessed in patients (pt) previously treated with trastuzumab, pertuzumab, and a taxane (H+P+T). Several mechanisms of resistance have been hypothesized in pts progressing following H+P+T, including acquired alterations in the ERBB (HER) family proteins, reactivation of bypass or parallel pathways, or selective elimination of HER2-overexpressing clones. Loss of HER2 amp has been shown to occur in 25-35% of pts with residual tumor after neoadjuvant therapy or in metastatic disease after initial therapy with chemotherapy and HER2-targeted agents. Data on concordance of HER2 status between tissue and blood is limited. In 7 pts with cfDNA HER2 amp, concomitant tissue was concordant in all 7 pairs and response to anti-HER2 therapy occurred in 6. In our study we have retrospectively analyzed cfDNA in blood samples obtained at study entry.

Methods:
Eligible pts had prior H+P+T as neoadjuvant therapy, or 1st-line metastatic disease, measurable disease, ECOG PS ≤2, and adequate hematologic, renal, and liver function. Pts with stable brain metastases were eligible. Treatment consisted of T-DM1 3.6 mg/kg iv q3wk and N 120, 160, 200, or 240 mg/d using a 3+3 dose-escalation design. HER2+ was determined at initial diagnosis; tissue confirmation at study entry (after H+P+T progression) was not required. Blood was collected in for pharmacokinetic analyses of N peak and trough, and for cfDNA using the Guardant360 assay, which is a 73-gene next-generation cfDNA-sequencing panel that detects SNVs, indels, CNAs, and fusions, utilizing Digital Sequencing and custom bioinformatics methods for error correction. The cut-off for HER2 amp was a copy number of ≥2.0 established by Guardant based on training-set data.

Results:
There were 27 H+P+T-resistant pts enrolled and all pts had a blood sample analyzed for HER2 amp. Eighteen pts were evaluable for efficacy at 6 wks and 11 pts at 12 wks. Dose-limiting toxicity occurred in 6 pts during cycle 1, 1 pt was withdrawn for non-compliance, and 2 pts were withdrawn for disease complications. The recommended phase II dose of N was determined to be 160 mg/d. Responses were seen at all dose-levels of N. Pharmacokinetic analyses did not show a clear relationship with either peak or trough and dose-level. Ten pts showed HER2 amp in blood and 17 were non-amp. Of 18 pts evaluable after 2 cycles (6 wks), 12 pts had an objective response (7 amp; 5 non-amp) and 5 had progressive disease (1 amp; 4 non-amp). At 12 wks, there were 3 CRs and 8 PRs (7 amp; 4 non-amp). All CRs were in amp pts and lasted 364, 510, and 859+ days.

Conclusions:
HER2 amp as determined by cfDNA was found in 10 of 27 pts. The deeper and more prolonged (>12 wk) responses occurred in 7 of 10 amp HER2 pts v 4 of 17 non-amp HER2 pts (p=0.04). In our ongoing phase II study of this regimen concomitant tissue and blood will be analyzed to better understand potential benefit or lack of benefit, with continued use of anti-HER2 therapy after progression on anti-HER2 therapies.

Co-occurring gain-of-function mutations in HER2 and HER3 cooperate to enhance HER2/HER3 binding, HER-dependent signaling, and breast cancer growth

Ariella B Hanker¹, James P Koch², Dan Ye¹, Gregory Sliwoski³, Jonathan Sheehan³, Lisa N Kinch¹, Monica Red Brewer², Jie He⁴, Vincent A Miller⁴, Alshad S Lalani⁵, Richard E Cutler, Jr.⁵, Sarah Croessmann², Daniel J Zabransky⁶, Jens Meiler³ and Carlos L Arteaga¹. ¹UT Southwestern Medical Center, Nashville, TN; ²Vanderbilt University Medical Center, Nashville, TN; ³Vanderbilt University, Nashville, TN; ⁴Foundation Medicine, Cambridge, MA; ⁵Puma Biotechnology, Los Angeles, CA and ⁶Johns Hopkins University, Baltimore, MD.

*ERBB2*, the gene encoding HER2, is mutated in 2-4% of breast cancers. The HER2 tyrosine kinase inhibitor neratinib has shown clinical activity against breast cancers harboring HER2 activating mutations, suggesting these tumors depend on HER2 signaling. Co-occurring HER2 and HER3 (*ERBB3*) mutations have been reported in patients who respond to neratinib (Hanker et al., *Cancer Discov.* 2017) suggesting the possibility of cooperativity of both oncogenes. Co-expression of the mutant intracellular domains of HER2 and HER3 in HEK293 cells enhanced phosphorylation of HER3 and ERK compared to expression of either mutant alone, which was blocked by 100 nM neratinib. Interrogation of TCGA, METABRIC, Project GENIE, and Foundation Medicine datasets revealed that gain-of-function mutations in *ERBB2* and *ERBB3* co-occur with a statistically significant frequency. For example, in GENIE, *ERBB2* mutations co-occur with mutations in *ERBB3* (8.3% of *ERBB2*-mutant vs 2.3% of *ERBB2* WT; q=1.37x10⁻¹⁰).

We hypothesized that co-occurring mutations in HER2 and HER3 cooperate to enhance HER2 signaling and dependence and breast cancer progression.

Thirty-four unique breast cancers were found to harbor co-occurring mutations in HER2 and HER3, the most common of which were *ERBB2*L755S/*ERBB3*E928G (n=10), *ERBB2*V777L/*ERBB3*E928G (n=6), and *ERBB2*L869R/Q/*ERBB3*E928G (n=4). Using co-immunoprecipitation assays with HER2 and HER3 antibodies in transfected HEK293 cells, we found that co-expression of HER3E928G with wild type (WT) HER2, or co-expression of HER2L755S or HER2L869R with HER3WT, slightly increased HER2-HER3 dimerization. However, binding was strongest between double mutants. This was accompanied by the highest levels of Y1289p-HER3 in cells expressing both HER3E928G and each HER2L755S, HER2V777L, or HER2L869R compared to cells expressing each HER2 or HER3 mutant with a respective WT heterodimer partner. Structural modeling of the HER2L869R/HER3E928G double-mutant predicted that the HER3 mutation, located at the dimer interface, may enhance heterodimerization of the kinase domains through decreased bulk and electrostatic repulsion. We also noted that the HER2L755S mutation is predicted to be in close proximity to HER3E928G (<4 Å) and may impact binding affinity. Investigation of the structural basis for the enhanced binding of other double mutants is in progress.

MCF7 “knock-in” cells incorporating HER2L755S, HER2V777L, or HER2L869R (or HER2WT) were stably transduced with HER3E928G or HER3WT. Co-expression of double mutants strongly enhanced estrogen-independent growth in 3D Matrigel over cells expressing either mutant alone. We are currently testing inhibitors of HER2/HER3 signaling, including neratinib ± trastuzumab, trastuzumab + pertuzumab, and the ERBB1-3 antibody mixture Sym013, to determine therapeutic strategies to block the cooperative growth induced by co-occurring HER2 and HER3 mutations.

**Conclusions:** Co-expression of mutant HER2 and mutant HER3 promotes HER2/HER binding, HER3 phosphorylation, and breast tumor cell proliferation. We aim to identify therapeutic vulnerabilities for patients with co-occurring HER2 and HER3 mutations.
Background: HER2 mutations define a rare subset of metastatic breast cancer (MBC) with a unique mechanism of oncogenic addiction to HER2 signaling. Neratinib, an irreversible pan-HER tyrosine kinase inhibitor, has demonstrated single-agent clinical activity in HER2-mutant MBC. In HER2-mutant, HR+ MBC, neratinib + fulvestrant (N+F) appears synergistic vs single-agent neratinib, possibly due to more complete inhibition of bi-directional signaling between HER2 and estrogen receptors. Here we describe interim efficacy results of the expanded HER2-mutant, HR+ MBC cohort treated with N+F from SUMMIT (NCT01953926).

Methods: HR+ MBC patients (pts) with HER2 mutations documented by local testing received oral neratinib 240mg qd and intramuscular fulvestrant (labeled dose). Intensive loperamide prophylaxis was mandatory during cycle 1. Efficacy endpoints include objective response rate at week 8 (ORR\textsubscript{8}); confirmed objective response rate (ORR); clinical benefit rate (CBR); duration of response (DOR); progression-free survival (PFS); response was assessed by RECIST 1.1 and/or PET Response Criteria. Genomic profiling from fresh/archival tumor tissues and/or plasma cfDNA was performed retrospectively by next-generation sequencing (MSK-IMPACT).

Results: As of 18 May 2018, 46 HER2-mutant HR+ MBC pts have been treated with N+F. Most pts were pretreated, with 91% having received prior anti-cancer medication for MBC (range 0–10). ORR was 33% and median DOR in the 15 pts with a confirmed response was 9.2 months (95% CI 3.9–18.5). Twenty-four pts had prior fulvestrant exposure, and 19 had received prior CDK4/6i-based therapy. Clinical activity was observed with ORRs of 17% and 26% in prior fulvestrant-treated and prior CDK4/6i-treated pts, respectively. ORRs by HER2 mutation were: V777L 63% (5/8 pts); S310F/Y 67% (4/6 pts); G778_P780dup 50% (3/6 pts). Diarrhea was the most common adverse event (grade 3; 24%; grade 4; 0%). Median cumulative duration of grade 3 diarrhea was 3 days. There were no treatment discontinuations due to diarrhea.

\(^a\)For pts with both RECIST- and PET-evaluable lesions, the best of either RECIST or PET response was used to determine response; the earliest progression by RECIST or PET was used for progression; \(^b\)Pt has not progressed; \(^c\)Kaplan-Meier analysis; NA, not applicable

**Conclusions:** N+F demonstrates encouraging clinical activity with durable responses in heavily pretreated pts with HER2-mutant, HR+ MBC. Of note, responses were observed in pts who had received prior fulvestrant or CDK4/6 inhibitors. No new safety signals were identified; the rate of diarrhea was similar to single-agent neratinib and not dose limiting. Updated data after additional follow-up and genomic data will be presented.
A phase II pre-surgical trial of lapatinib for the treatment of women with HER2 positive or EGFR positive ductal carcinoma in situ

Parijatham S Thomas, Alejandro Contreras, Sandhya Pruthi, Helen Krontiras, Mothaffar Rimawi, Judy Garber, Tao Wang, Susan G Hilsenbeck, Lana A Vornik, Tona Gilmer, Helen Krontiras, Brandy M Heckman-Stoddard, Barbara Dunn, Henry Kuerer and Powel H Brown. 1University of Texas at MD Anderson Cancer Center, Houston, TX; 2Mayo Clinic, Rochester, MN; 3University of Alabama Medical Center, Birmingham, AL; 4Baylor College of Medicine, Houston, TX; 5Dana Farber Cancer Institute, Boston, MA; 6National Cancer Institute, Bethesda, MD and 7Glaxo Smith Kline, Durham, NC.

Background: Estrogen receptor (ER)-negative tumors and human epidermal growth factor 2-Neu (HER2) positive breast cancers are known to be more clinically aggressive subtypes of breast cancer and account for 30% of all breast cancers. Women with HER2 + breast cancers, whether ER+ or ER -, require cytotoxic chemotherapy with a HER2-targeting agent, and often have adverse outcomes. Thus, preventive agents are needed to reduce the incidence of these subtypes of aggressive breast cancer. Lapatinib, a dual tyrosine kinase inhibitor, inhibits epidermal growth factor receptors (EGFR) and HER2 kinases and has shown to decrease breast cell proliferation in invasive breast cancer and adjacent premalignant lesions. Therefore, we conducted a multi-institutional randomized Phase II clinical trial to study the effects of the signal transduction inhibitor lapatinib in women with HER2-positive or EGFR-positive ductal carcinoma in situ (DCIS).

Methods: Randomized participants received either lapatinib (750mg, 1000mg, or 1500mg) or placebo daily for 2-6 weeks prior to their surgery. After minimal accrual, the trial was later amended to lapatinib 1000mg or placebo. Pre-treatment breast tissue was obtained from initial diagnostic core biopsy and post-treatment breast tissue was obtained from surgical excision specimen. Blood was obtained prior to surgery to assess serum lapatinib level. Participants kept a daily symptom assessment log and had a cardiac assessment at baseline and prior to surgery. Patients were instructed to take drug up to and including the day before surgery. The dual primary endpoint for this study was change in proliferation in pre- versus post-treatment biopsies between the two treatment arms, as measured by Ki67 as well as toxicity assessment. Secondary endpoints included incidence of DCIS at surgery and modulation of tissue biomarker expression in growth factor receptors (EGFR, ErbB2); phosphorylated growth factor receptor (phospho-ErbB2); signal transduction markers (MAPK, phospho-MAPK); hormone receptors (ER, PR); and p27.

Results: Twenty-two women (mean age: 51; range: 32-66) with HER2+ or EGFR+ DCIS were treated with lapatinib (1,000 or 1,500 mg) or placebo for 2–6 weeks prior to surgical excision. Ki67 expression was significantly decreased in the lapatinib treatment arms compared to placebo (\(p=0.0122\)). Diarrhea, fatigue, and skin reactions were notable adverse events that occurred predominately in the lapatinib arm compared to placebo. No grade 3 or 4 events related to the study drug were noted during the study. No changes were noted in cardiac function. DCIS was present in all surgical specimens in both arms. Invasive breast cancer was noted in 1 patient on lapatinib 1000mg and 3 patients on placebo. No statistically significant changes were noted in signal transduction biomarkers

Conclusion: These results demonstrate the effectiveness of lapatinib in reducing proliferation in women with EGFR+ or HER2+ DCIS. Even low-grade toxicities can deter use of an agent in the prevention setting. This and the lack of a risk model for HER2+ and triple negative breast cancer make the development of larger scale clinical prevention trials of lapatinib for the prevention a challenge.
Assessment of the tumor immune environment in inflammatory breast cancer treated with neoadjuvant dual-HER2 blockade

Sonia Pernas¹, Shom Goel¹, Beth T Harrison², Jiani Hu¹, Nathan Johnson³, Meredith Regan¹, Linda A Chichester¹, Faina Nakhlis², Emily J Schlosnagle¹, Grace Winship¹, Jennifer L Guerriero¹, Heather Parsons¹, Elizabeth A Mittendorf² and Beth Overmoyer¹.
¹Dana Farber Cancer Institute, Boston, MA; ²Brigham and Women's Hospital, Boston, MA and ³Harvard Medical School, Boston, MA.

Background: Inflammatory breast cancer (IBC) is an aggressive form of breast cancer that remains relatively understudied. We examined the efficacy of neoadjuvant dual-HER2 blockade (trastuzumab (H) and pertuzumab (P)) combined with paclitaxel (T) in HER2+ IBC, including a planned analysis to elucidate associations between the tumor immune microenvironment profile and response to therapy.

Methods: An IRB-approved, single-arm phase II trial for patients (pts) with newly diagnosed HER2+ IBC was conducted. Pts had a pre-treatment biopsy of the affected breast (D1) followed by a loading dose of HP. A second biopsy was performed 1 week (wk) later (D8), when T (80mg/m²/wk x 16 wks) was added to HP. Responding pts underwent modified radical mastectomy (MRM) where residual disease was collected. The primary objective was to determine the rate of pathologic complete response (pCR) defined as ypT0/isN0. Residual Cancer Burden (RCB) was also determined. Tumor specimens from D1, D8 and MRM were assessed for disease cellularity and scored for percentage of tumor infiltrating lymphocytes (TILs): low=0-10%, intermediate=11-59%, high>60%. RNA-sequencing was performed on tumor tissue from D1 and D8 to explore the impact of short-term HP treatment on the tumor transcriptomic profile and to identify potential predictors of pCR.

Results: 23 pts with HER2+ IBC were enrolled between 8/2013-6/2017. Mean age was 48 years (range 32-74); 11 pts (48%) had estrogen and progesterone receptor (ER/PR) negative disease. Matched tumor biopsies (D1, D8) were obtained in all 23 pts; 21 underwent MRM; 1 was lost to follow-up and 1 had disease progression. In the intent to treat analysis, 10/23 (43%) pts achieved a pCR and 7 (30%) had RCB-1. Ten of the 22 evaluable pts achieved a pCR (45.5%). TILs were evaluable in 20/23 (87%) matched tumor biopsies (D1, D8). Among the D1 biopsy specimens: 19 (95%) had low levels, 2 (10%) had intermediate levels, and none had high levels. When D1 TIL levels were compared with D8 levels, 3(15%) had an increase in TILs, 16(80%) had no change in TIL levels, and 1(5%) had a decrease in the level of TILs. Both samples with intermediate levels and 2 of 3 samples with high levels of TILs on D1 and D8 were seen in ER/PR negative disease. An evaluation of biopsy specimens associated with subsequent pCR using GO enrichment analysis from the RNA-Seq data showed significant upregulation of several immune-process related gene expression signatures both at D1 and D8 (e.g. antigen processing and presentation, TCR signaling, NK cell cytotoxicity, p-value: 2.99E-48 to 1.39E-16) when compared with those associated with residual disease at the time of MRM. Across the entire cohort, D8 biopsies showed evidence of upregulated anti-tumor immunity compared to D1 biopsies (p-value: 9.57E-06 to 0.012). Notably, this change from D1 to D8 was largely restricted to tumors that achieved a pCR.

Conclusion: THP for 16 weeks was a highly effective treatment for HER2+ IBC. Immune activation as determined by gene expression signatures predicted pCR, and moreover upregulation of anti-tumor immunity after 1 wk of HP might further predict a complete pathologic response to therapy. ClinicalTrials.gov identifier: NCT01796197
Efficacy of HER2 inhibitors in metastatic breast cancer by discordance in HER2 amplification status between primary and metastatic breast cancer

Elisa Van Raemdonck1, Patrick Berteloot1, Annoushka Laenen1, Sileny Han1, Els Van Nieuwenhuysen1, Rawand Salihi1, Nicole Concin1, Ignace Vergote1, Giuseppe Floris2, Hans Wildiers1, Kevin Punie1 and Patrick Neven1. 1KU Leuven - University of Leuven, Leuven, Belgium and 2KU Leuven - University of Leuven, Laboratory of Translational Cell & Tissue Research and University of Leuven, Department of Pathology, Leuven, Belgium.

Purpose:
In stage IV breast cancer (BC), discordance in the human epidermal growth factor receptor 2 (HER2) amplification status between primary and metastatic BC might affect efficacy of HER2-targeted agents. We studied progression free (PFS) and overall survival (OS) dependent on HER2 concordance in patients treated with a first line taxane-trastuzumab combination and later line trastuzumab-emtansine (T-DM1).

Patients and Methods:
This retrospective monocentric study included 76 patients with metastatic BC under treatment with trastuzumab in which a biopsy from both the primary and metastatic site was available. HER2 amplification status, sex-steroid receptor status, Nottingham prognostic index, distant metastasis-free interval and consecutive lines of therapy were retrieved from patients' reports. The Kaplan-Meier method was used for estimating PFS/OS and log-rank test for analyzing between group differences. A Cox model is used for testing difference between groups while correcting for Pertuzumab. Multivariable Cox regression is used to model OS as a function group, correcting for possible confounders.

Results:
Discordance in HER2 amplification status was seen in 30 out of 76 patients (39%), 11 patients lost HER2 amplification in the metastatic lesion (HER2lost) while 19 acquired HER2 amplification (HER2acquired). The other 46 patients had a HER2 amplification on both primary and metastatic site (HER2stable). The HER2lost group had a significant lower median PFS (PFS= 5.5 months) for taxane-trastuzumab, after correcting for pertuzumab, compared to the HER2stable group (PFS= 9 months, corrected p= 0.0146) and HER2acquired group (PFS=14 months, corrected p=0.0121). For T-DM1 treatment, both discordant groups, HER2acquired (PFS=1.1 months, p=0.0373) and HER2lost (PFS=1.5 months, p=0.0116), had a significant lower PFS compared to the HER2stable group (PFS=6.0 months). After correcting for possible confounders, HER2lost had a significant worse OS compared to HER2stable (HR 0.187, 95% CI 0.079 – 0.439) and HER2acquired (HR 0.147, 95% 0.058-0.378).

Conclusion:
Loss of HER2 amplification in metastatic lesions seems to have a negative predictive value for PFS on HER2-targeted agents and negative prognostic impact on OS. Acquiring of HER2 amplification was predictive for lower PFS on T-DM1 but wasn't predictive for lower PFS on taxane-trastuzumab.
Higher serum PD-L1 predicts for increased overall survival to lapatinib vs trastuzumab in the phase 3 CCTG MA.31 trial

Prashanth R Moku1, Lois E Shepherd2, Suhail M Ali1, Kim Leitzel1, Wendy E Parulekar2, Liting Zhu2, Shakeel Virk2, Dora Nomikos2, Samuel Aparicio4, Karen A Gelmon4, Joseph J Drabick1, Leah Cream1, Scott E Halstead1, Todd Umstead1, Daniel McKeone1, Ashok Madukuri1, Hyma V Polimera1, Aamnah Ali1, Joyson Poulse1, Neha Pancholy1, Howard Spiegel5, Vinod Nagabhauru4, Bingshu E Chen2 and Allan Lipton1. 1Penn State Hershey Medical Center, Hershey, PA; 2Queen's University, Canadian Cancer Trials Group, Kingston, ON, Canada; 3Lebanon VA Medical Center, Lebanon, PA; 4British Columbia Cancer Agency, Vancouver, BC, Canada; 5ProteinSimple, San Jose, CA and 6Pinnacle Health System, Harrisburg, PA.

Background: In the CCTG (Canadian Clinical Trials Group) MA.31 randomized phase 3 trial, the trastuzumab-taxane combination led to longer PFS than lapatinib-taxane in HER2-positive metastatic breast cancer (MBC). We previously reported the prognostic utility of pretreatment serum PD-L1 in the trastuzumab arm of MA.31 (ASCO 2018, #1031), and here we evaluate serum PD-L1 in the lapatinib arm, and in the whole trial. Higher serum PD-L1 has been reported to be associated with reduced response to treatment with the immune checkpoint inhibitors in melanoma and lung cancer.

Methods: MA.31 accrued 652 centrally and/or locally-identified HER2-positive patients; 186 in the trastuzumab arm, and 202 in the lapatinib arm had pretreatment serum available. The ELLA immunoassay platform (ProteinSimple, San Jose, CA) was used to quantitate serum PD-L1. Step-wise forward Cox multivariate analysis was used for PFS and OS, and testing for treatment-biomarker interaction was based on the local partial-likelihood method (Liu Y, Jiang W, and Chen BE, Statistics in Medicine 34, 3516-3530, 2015).

Results: In the total study population, pretreatment serum PD-L1 concentration had a median of 86.2 pg/ml, and 25% and 75% interquartiles of 64.1 and 134.3 pg/ml, respectively. In univariate analysis in the whole trial, and within both treatment arms, serum PD-L1 was not a significant biomarker for PFS. For OS, higher serum PD-L1 (as a continuous variable) was significant for shorter OS within the trastuzumab arm (HR=3.84, p=0.04), but was not associated with OS in the lapatinib arm (p=0.37). In the whole trial, in multivariate analysis for OS [15 covariates included: age, race, ECOG status, anthracyclines, other chemo, endocrine, radio, other prior adjuvant therapy, disease status, ER status, PR status, Ki67 (log transformed), CK5, EGFR, treatment arm, and serum PD-L1 (with median cut point)], serum PD-L1 remained a significant independent covariate (HR= 2.27, p= 0.001) (Table). There was significant interaction between treatment arm and continuous serum PD-L1 (Bootstrap method, p=0.0025); above 214.2 pg/ml serum PD-L1 (89% percentile), higher pretreatment serum PD-L1 was associated with a shorter OS to trastuzumab treatment, but longer OS to lapatinib treatment.

Conclusions: In the CCTG MA.31 trial, serum PD-L1 was a significant predictive factor: higher pretreatment serum PD-L1 was associated with a shorter OS to trastuzumab treatment, but longer OS to lapatinib treatment. Immune evasion may decrease the effectiveness of trastuzumab therapy. Further evaluation of elevated serum PD-L1 in the advanced breast cancer setting is warranted to identify HER2-positive MBC patients who may benefit from novel immune-targeted therapies in addition to trastuzumab.

HER2/ERBB2 status in “HER2 equivocal” breast cancers by FISH and ASCO-CAP guidelines: False-positives due to heterozygous deletions of alternative control loci

Michael F Press¹, Jose A Seoane², Christina Curtis³, Emmanuel Quinaux³, Roberta Guzman⁴, Guido Sauter⁴, Wolfgang Eiermann⁵, John R Mackey⁶, Nicholas Robert⁷, Tadeusz Pienkowski⁸, John Crown⁹, Miguel Martin¹⁰, Vicente Valero¹¹, Valerie Bee¹², Yanling Ma¹, Ivonne Villalobos¹ and Dennis J Slamon¹³. ¹USC/Norris Comprehensive Cancer Center, Los Angeles, CA; ²Stanford University, Stanford, CA; ³International Drug Development Institute, Louvain-la-Neuve, Belgium; ⁴University of Hamburg, Hamburg, Germany; ⁵Frauenklinik vom Roten Kreuz, Munich, Germany; ⁶University of Alberta, Edmonton, Canada; ⁷Virginia Cancer Specialists/US Oncology Research Network, Fairfax, VA; ⁸Postgraduate Medical Education Center, Warsaw, Poland; ⁹St Vincent's University Hospital, Dublin, Ireland; ¹⁰Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain; ¹¹M.D. Anderson Cancer Center, Houston, TX; ¹²Cancer International Research Group/Translational Research in Oncology, Paris, France and ¹³Geffen School of Medicine at UCLA, Los Angeles, CA.

Background. The ASCO-CAP guidelines for HER2 testing by fluorescence in situ hybridization (FISH) have a category, referred to as “equivocal” (average HER2 copies per tumor cell ≥4-6 with HER2/CEP17 ratio <2·0), which is neither “HER2-positive” nor “HER2-negative”. Approximately 4% - 12% of invasive breast cancers are “HER2-equivocal” based on FISH. Cancers in this category may be resolved as “negative” or “positive” by FISH alternative control probes (2013/2014 guidelines) or HER2 immunohistochemistry (IHC) (2018 update). Our objectives were to evaluate the following hypotheses: 1.) Genetic loci used as alternative controls show heterozygous deletion in a substantial proportion of breast cancers; 2.) Use of these loci for assessment of HER2 by FISH leads to false-positives; 3.) HER2 FISH false-positive breast cancer patients have outcomes that do not differ from clinical outcomes for HER2-negative breast cancer patients; and 4.) HER2-equivocal breast cancers seldom show HER2 protein overexpression (IHC 3+).

Methods. We retrospectively assessed the use of chromosome 17 p-arm and q-arm alternative control genomic sites (TP53, D17S122, SMS, RARA, TOP2A), as recommended by the 2013/2014 ASCO-CAP guidelines, in patients whose data were available through the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC)(N=1980) or whose tissues were available from the BCIRG-005 clinical trial (N=3298). We used either FDA-approved HER2 IHC (HercepTest) or laboratory-developed HER2 (10H8) IHC assays to assess HER2 protein expression.

Results. Using METABRIC we found heterozygous deletions, particularly in specific p-arm sites, were common in both HER2-amplified and HER2-not-amplified breast cancers. Use of alternative control probes from these regions to assess HER2 by FISH in “HER2 equivocal” as well as HER2-not-amplified breast cancers resulted in high rates of false-positive ratios (HER2-to-alternative control ratio ≥2·0) due to heterozygous deletions of control p-arm genomic sites used as ratio denominators. Misclassifications of HER2 status was observed not only in breast cancers with ASCO-CAP “equivocal” status but also in breast cancers with an average of <4·0 HER2 copies per tumor cell. These deletions were also identified by FISH. IHC demonstrated <1% of FISH “HER2-equivocal” breast cancers in BCIRG-005 had IHC3+ immunostaining, consistent with HER2-not-amplified status. Clinical outcomes of “HER2-equivocal” breast cancer patients with HER2-to-alternative control ratio ≥2·0 did not differ significantly from clinical outcomes of those with HER2-to-alternative control ratio<2·0.

Conclusion. Using chromosome 17 p-arm alternative controls, as recommended by 2013/2014 ASCO-CAP guidelines, instead of CEP17 for resolution of “HER2 equivocal” cases, is problematic due to frequent heterozygous deletions of these loci in breast cancers. The indiscriminate use of alternative control probes to calculate a HER2 FISH ratio in “HER2-equivocal” breast cancers leads to false-positive interpretations of HER2 status resulting from unrecognized heterozygous deletions in one or more of these alternative control genomic sites and incorrect HER2 ratio determinations.
Central nervous system as first site of relapse in patients with HER2 positive early breast cancer treated in the BCIRG-006 trial

Arlene Chan¹, Gonzalo Spera², Andres Machado², Helena Fung³, Valerie Bee⁴, Rodrigo Fresco² and Dennis J Slamon⁵.

¹Breast Cancer Research Centre, Breast Clinical Trials Unit, School of Medicine, Curtin University, Perth, Western Australia, Australia; ²Translational Research in Oncology (TRIO), Medical Unit, Montevideo, Uruguay; ³Translational Research in Oncology (TRIO), Biostatistics, Edmonton, AB, Canada; ⁴Translational Research in Oncology (TRIO), Project Management, Paris, France and ⁵University of California, Los Angeles.

Introduction: Central Nervous System (CNS) metastases as first site of relapse is seen in 2-3% of patients with HER2+ early breast cancer (EBC) during or after treatment with adjuvant trastuzumab. Data about long-term follow-up outcomes in this population is scarce. Methodology: BCIRG-006 was designed to assess the efficacy and safety of two trastuzumab-based regimens compared to a standard (non-trastuzumab) regimen in the adjuvant treatment of HER2+ EBC. 3,222 patients were randomized to standard AC-T or two trastuzumab-based regimens (AC-TH or TCH). Ten year follow-up outcomes were previously presented; we have used this data to assess the frequency and course of CNS relapses as first site of distant recurrence. DFS and OS in these patients were estimated and compared using the Kaplan-Meier method and Log-Rank test respectively. Univariate and multivariate analyses for DFS were conducted considering patient's age, nodal status, tumor size and estrogen receptor (ER) status in the primary tumor. Results: Of the 3,222 patients randomized, 575 (17.8%) experienced a distant relapse and in 17.5% of these (n=101) CNS was the first site of recurrence. With a median follow-up of 10.3 years, the frequency of CNS relapses did not differ when comparing the trastuzumab containing arms with the control arm (OR 0.86, 95% CI: 0.56-1.33; p= 0.519). No difference was observed either between AC-TH and TCH (OR 1.14, 95% CI: 0.67-1.94; p= 0.704). There were no differences in DFS (HR 1.21, 95% CI: 0.74-1.99; p= 0.621) nor in OS (HR 0.74, 95% CI: 0.43-1.27; p= 0.377) between AC-T, AC-TH and TCH arms. Positive axillary nodes (≥4 nodes) and ER negative status at baseline remained independent risk factors for CNS relapse after univariate and multivariate analysis (HR 0.60, 95% CI: 0.8-0.95; p= 0.007 for nodal status and HR 0.56, 95% CI: 0.37-0.85; p= 0.029 for ER status). Conclusion: Among the pivotal adjuvant trastuzumab trials, BCIRG-006 is the one with the longest median FUP in which data about CNS relapses has been presented. CNS relapse in patients in this trial was an infrequent event. Its frequency and outcomes were similar across the three treatment arms. Patients with ER negative and/or ≥ 4 positive nodes are at higher risk of CNS relapse irrespective of trastuzumab therapy and may be the patient population where research efforts should be focused.

A new additive diagnostic assay for breast cancer screening - Biochemical infrared analysis of immune cells and plasma

Tanir Michal Allweis¹, Jürgen Schmitt² and Udi Zelig³. ¹Kaplan Medical Center, Rehovot, Israel; ²Synthon GmbH, Schriesheim, Germany and ³Todos Medical Ltd., Rehovot, Israel.

Background:
Screening for early detection of breast cancer is currently based on breast imaging. Screening mammography, the most commonly used imaging modality, has limited sensitivity, especially in dense breast tissue, and a significant rate of false positive results. An adjuvant blood-test based assay may improve breast cancer detection irrespective of breast density. In previously reported studies, Total Biochemical Infrared Analysis (TBIA) of peripheral blood mononuclear cells (PBMCs) and plasma was able to differentiate between patients with breast cancer and healthy controls or patients with benign breast disease. The TM-B1™ assay is based on TBIA technology and is intended for breast cancer screening. In the present study, the performance of the TM-B1™ assay was evaluated for cancer detection across breast densities.

Patients and Methods:
A total of 220 women were recruited to this IRB approved study: 50 women with newly diagnosed breast cancer, and two control groups – 79 patients with benign findings and 61 patients with no detectable abnormality. Twenty-nine women were withdrawn from the study (for eligibility or technical reasons), and the data presented refer to 190 cases. Breast cancer patients included 6 cases of DCIS, 1 of LCIS, 42 of IDC and 1 of ILC. Ten milliliters of blood were drawn and separated by Ficoll gradient method into PBMCs and plasma. The samples were dried on a zinc selenide optical window and analyzed by a FTIR spectrometer. The spectra were analyzed by the proprietary software TodoSpectra to distinguish between infrared spectra of cancer patients vs. patients with benign findings and healthy controls. The influence of age and breast density on TM-B1™ results were evaluated.

Results:
The TM-B1 assay obtained a sensitivity of 86 % and specificity of 98 % for breast cancer detection. The positive predictive value (PPV) was 95.1% and the negative predictive value (NPV) was 93.5%. Dense breast tissue (BIRADS categories C&D) was present in 55 % of the subjects. The specificity and sensitivity for patients with dense breasts was 99 % and 83 % respectively. No major differences in accuracy of TM-B1 were found due to patients’ age.

Conclusions:
TM-B1 in conjunction with current imaging techniques may contribute to early detection of breast cancer by increasing sensitivity and reducing false positive results and unnecessary biopsies. Further studies with larger patient numbers are required and under way to establish the utility of adding the TM-B1 assay to current standard screening for breast cancer.
MRI detection of residual disease following neoadjuvant chemotherapy (NAC) in the I-SPY 2 TRIAL

Wen Li, David Newitt, Bo La Yun, John Kornak, Bonnie Joe, Christina Yau, Hiroyuki Abe, Dulcy Wolverton, Erin Crane, Kathleen Ward, Michael Nelson, Bethany Niell, Jennifer Drudeiinis, Karen Oh, Kathy Brandt, Dae Hee Bang, Haydee Ojeda, Mohammad Eghtedari, Pulin Sheth, Wanda Bernreuter, Heidi Umphrey, Mark Rosen, Basak Dogan, Wei Yang, Laura Esserman and Nola Hylton. 1University of California, San Francisco, San Francisco, CA; 2University of Chicago, Chicago, IL; 3University of Colorado, Denver, CO; 4Georgetown University, Washington, DC; 5Loyola University, Maywood, IL; 6University of Minnesota, Minneapolis, MN; 7Moffitt Cancer Center, Tampa, FL; 8Oregon Health Science University, Portland, OR; 9Rochester Methodist Hospital, Rochester, MN; 10Swedish Medical Center, Seattle, WA; 11University of California, San Diego, San Diego, CA; 12University of Southern California, Los Angeles, CA; 13University of Alabama, Birmingham, AL; 14University of Pennsylvania, Philadelphia, PA; 15University of Texas Southwestern, Houston, TX and 16MD Anderson Cancer Center, Houston, TX.

Background: Detecting residual disease accurately using MRI after NAC to identify both responders and non-responders is essential for de-escalating therapy or redirecting patients to more effective treatment. The purpose of this study is to determine if the combination of longest diameter (LD) and functional tumor volume (FTV) from dynamic contrast enhanced (DCE-) MRI is superior to FTV alone or LD alone for assessing treatment response after neoadjuvant therapy in breast cancer patients.

Methods: Data from patients in the graduated drug arms of the I-SPY 2 trial were included in the analysis. Both LD and FTV were assessed using DCE-MRI after neoadjuvant therapy. LD was measured by the site radiologist as the longest dimension of the enhanced area on early post-contrast images. Functional tumor volume (FTV) was assessed as the sum of voxels with enhancement above specific thresholds within the pre-defined region-of-interest (ROI). A linearized variable was derived to represent the combination of FTV and LD. The area under the receiver operating characteristic curve (AUC) was used to evaluate the assessment of treatment response, pathologic complete response (pCR), defined as no invasive disease in the breast and lymph nodes, and in-breast pCR, defined as no invasive disease in the breast only. The analysis was performed in the full cohort and in breast cancer subtype defined by hormone receptor status and HER2 status.

Results: Among the patient cohort of N=675 with FTV and LD, 247 (37%) did and 428 (41%) did not achieve pCR after neoadjuvant therapy. pCR rates varied among HR/HER2 subtypes (HR+/HER2−: 19%; HR+/HER2+: 38%; HR-/HER2+: 71%; HR-/HER2−: ( triple negative, TN): 43%). In-breast pathologic complete response rates were slightly higher in each group (full: 41%; HR+/HER2−: 23%; HR+/HER2+: 43%; HR-/HER2+: 72%; HR-/HER2−: 49%). Table 1 shows AUCs for assessing pCR using FTV alone, LD alone, and the variable combining FTV and LD. Higher AUCs were observed in all patient groups using the combined variable. AUC of 0.79 (95% CI: 0.77, 0.81) was observed for the combined variable to assess pCR in the full cohort. AUCs varied from 0.69 to 0.86 among HR/HER2 subgroups (HR+/HER2−: 0.69; HR+/HER2+: 0.74; HR-/HER2+: 0.86; HR-/HER2−: 0.80), with no difference in assessing pCR or in-breast pCR. The performance is best for the HR- subtypes.

Conclusions: Both FTV and LD can be used in the assessment of invasive disease residual after neoadjuvant therapy. The combined variable of FTV and LD achieved highest AUCs, compared to using individual variable alone. Tools to improve performance in the HR+ subsets are underway.

Background

In clinically node-negative (cN0) breast cancer patients with triple negative (TN) and HER2+ disease and breast pathological complete response (breast pCR), low rates of nodal positivity after neoadjuvant chemotherapy (NAC) have been demonstrated. In these patients, the omission of surgical axillary staging has been proposed. However, this information is not routinely known preoperatively. We aimed to validate the correlation between pathologic breast response and pathologic nodal status, and evaluate the relationship between response of the breast tumor on MRI and pathologic nodal status after NAC in cN0 patients in the I-SPY2 trial.

Methods

We identified all patients with cT1-4 cN0 breast cancer prior to NAC from graduated arms of the I-SPY2 trial, a prospective neoadjuvant chemotherapy trial. Absence of residual disease post-NAC was defined as longest diameter (LD) of 0 mm on MRI. Breast pCR was defined as the absence of invasive tumor in the breast at surgery. Associations between ypN0 and patient, MRI, and tumor characteristics were assessed using chi-square tests and univariate regression.

Results

Of 365 cT1-4 cN0 patients included, 128 had HR+/HER2- tumors (35%), 60 HR+/HER2+ tumors (16%), 34 HR-/HER2+ tumors (9%) and 143 TN tumors (39%). Overall, 283 patients (78%) were ypN0 after NAC and 152 patients (42%) had a breast pCR. ypN0 rate was higher in patients with a breast pCR than those with residual disease (93% vs 66%, p<0.001). Patients with HR-/HER2+ and TN tumors were more likely to be ypN0 (97% and 87% respectively) than patients with HR+/HER2- and HR+/HER2+ disease (66% and 71% respectively, p<0.001). Other characteristics associated with ypN0 were tumor grade (grade I 57%, grade II 66%, grade III 84%; p=0.002), MammaPrint Classification (High Risk 1 68% and High Risk 2 87%; p<0.001) and absence of residual tumor in the breast on MRI (87% vs 72% in patients with evidence of tumor on MRI post-NAC/pre-surgery; p<0.001).

In patients with HR-/HER2+, HR+/HER2+, HR-/HER2+ or TN disease and a breast pCR, ypN0 rate was respectively 82%, 96%, 96% and 97% (table 1). In patients with HR+/HER2-, HR+/HER2+, HR-/HER2+ or TN disease and with no evidence of residual disease in the breast on MRI, rate of ypN0 was 71%, 80%, 94% and 96% respectively.

Conclusion

In cT1-4 cN0 breast cancer patients with HR+/HER2+, HR-/HER2+ and TN tumors and a breast pCR, ypN0 rates after NAC are extremely high. In patients with HR-/HER2+ and TN tumors with no residual breast disease on MRI after NAC and pre-surgery, ypN0 rates are high enough to consider omission of axillary surgery. In patients with HR+ tumors, MRI is unsuifficiently predictive for pathological response and can therefore not be used to select ypN0 patients. Research on the prediction of ypN0 in cN+ I-SPY2 patients is ongoing.

Molecular breast imaging and tomosynthesis to eliminate the reservoir of undetected cancer in dense breasts: The Density MATTERS trial

Deborah Rhodes¹, Katie Hunt¹, Amy Conners¹, Shannon Zingula¹, Dana Whaley¹, Richard Ellis², Jeanette Gasal Spilde², Ramila Mehta¹, Mei-Yin Polley¹, Michael O'Connor¹ and Carrie Hruska¹. ¹Mayo Clinic, Rochester, MN and ²Franciscan Skemp Mayo Clinic Health System, Lacrosse, WI.

Background
High mammographic breast density is the primary reason for missed cancers or delayed detection on mammography, and is associated with a higher rate of advanced and interval cancers which increase breast cancer mortality. Digital breast tomosynthesis (DBT) has been shown to reduce false positive findings relative to 2D mammography but does not eliminate the potential for tumor masking in dense breasts due to the similar x-ray attenuation characteristics of tumors and normal fibroglandular tissue. Molecular Breast Imaging (MBI) performed with a dedicated gamma camera to detect functional uptake of a radiotracer, Tc-99m sestamibi, has been shown to reveal breast cancers obscured by density on mammography. In single-institution studies, adding MBI to 2D mammography in women with dense breasts detected an additional 5 to 10 invasive cancers per 1000 screened, with modest increases in recall rate (6 to 8%) at a lower cost-per-cancer detected than mammography alone. Despite this promising evidence, the lack of multicenter trial data has limited wider acceptance. Also, MBI has yet to be compared to DBT, which in some centers has replaced 2D mammography screening. We present interim results from a multicenter trial comparing cancer detection rate of DBT and MBI in screening of women with mammographically dense breasts.

Methods
In this ongoing, prospective, multicenter clinical trial, asymptomatic women aged 40-75 years with dense breasts on prior mammogram and no prior history of supplemental screening are invited to undergo two annual rounds of concurrent DBT and MBI. MBI is performed with injection of 300 MBq Tc-99m sestamibi with a dual-head semiconductor-based gamma camera. Screening tests are interpreted independently. Here, preliminary cancer detection rates (cancers per 1000 women screened), recall rates, and biopsy rates of DBT and MBI for initial screening are reported.

Results
In 537 women out of a planned 3000 who have completed the first round of screening, 7 cancers were detected: one by DBT only and 6 by MBI only, giving cancer detection rates of 1.9 for DBT vs. 11.2 for MBI and incremental cancer detection rate of 9.3 for MBI. The one DBT-only cancer was a node-negative 0.8 cm invasive lobular carcinoma. All 6 cancers detected by MBI were invasive; 5 of 6 were node negative (median size 1.0 cm; range 0.6 to 2.6 cm). Recall rate was 11% (60/537) for DBT alone; 16% (84/537) for MBI alone, and 21% (115/537) for the combination. Biopsy was prompted by DBT in 13 patients (PPV 8% [1/13]); by MBI in 23 patients (PPV 26% [6/23]); and by the combination of modalities in 33 (PPV 21% [7/33]).

Conclusion
These preliminary results demonstrate that MBI detects invasive breast cancers occult on DBT in dense breasts. Data from a second screening round will allow calculation of sensitivity and specificity, and determination of the impact of screening MBI in reducing advanced (> 2 cm) and interval cancers. Additional planned analyses will evaluate a denoising algorithm for further reduction in MBI radiation dose to match that of DBT.
PET imaging of PARP-1 expression in breast cancer

Elizabeth S McDonald¹, Sean Carlin¹, Kara N Maxwell¹, Anupma Nayak¹, Robert K Doot¹, Austin R Pantel¹, Michael D Farwell¹, Daniel A Pryma¹, Amy S Clark¹, Payal Shah¹, Angela M DeMichele¹, Amy Ziober¹, Erin K Schubert¹, Karen Palmer¹, Hsiaoju S Lee¹, Jennifer Matro¹, Lucy de la Cruz¹, Julia Tchou¹, David N Anderson¹, Michael D Feldman¹, Regan E Sheffer¹, Hayley Knollman¹, Mitchell D Schnall¹, Mehran Makvandi¹, Susan Domchek¹, Rebecca A Hubbard¹, Robert H Mach¹ and David A Mankoff¹. ¹University of Pennsylvania, Philadelphia, PA.

¹⁸F-FluorThanatrace ([¹⁸F]-FTT) is a novel radiotracer shown to quantify Poly [ADP-ribose] polymerase 1 (PARP-1) expression in vitro and in vivo through a receptor-ligand interaction. A recent study at the University of Pennsylvania in women with ovarian cancer demonstrated in vivo visualization of PARP-1 expression in tumors using this radiotracer that closely correlated with an in vitro assay of PARP-1 in tumor tissue (Makvandi, M. J. Clin. Invest. 128:2116, 2018). A radioligand with PARP-1 specificity, [¹²⁵I]-KX1, was also developed as a companion tool for ex vivo evaluation of PARP-1 expression and PARP inhibitor (PARPi) drug occupancy by radioligand binding assay (Makvandi, M. Cancer Res. 76:4516, 2016). As the first step in validating this biomarker in breast cancer, we performed a prospective clinical trial comparing in vivo [¹⁸F]-FTT uptake and ex vivo PARP-1 expression in women with primary breast cancer.

Methods: 24 patients with Stage I-IV primary breast cancer were imaged with [¹⁸F]-FTT prior to any therapy including surgery. We correlated in vivo uptake with ex vivo immunohistochemistry (IHC) for PARP-1 and [¹²⁵I]-KX1 autoradiography in untreated surgical specimens. Tumors were analyzed for alterations in DNA repair genes, copy number-based as well as mutational signatures indicative of homologous recombination deficiency (HRD) and mutational burden, using our established protocol (Maxwell, KN, Nature Commun. 8:319, 2017).

Results: [¹⁸F]-FTT uptake was visualized above background in all primary breast tumors and known metastases. Two areas of unexpected uptake revealed an unknown contralateral breast cancer and an ovarian carcinoid, respectively. We expected that uptake might be highest in triple negative breast cancer (TNBC), where PARPi have been most heavily studied. However, a range of tracer uptake was observed in tumors independent of breast cancer subtype (hormone receptor positive/HER2 negative, TNBC, HER2+) and BRCA status. Uptake ratios (SUVmax tumor/SUV max opposite breast) ranged from 1.2-10.5 with a median 4.0. Ex vivo[¹²⁵I]-KX1 autoradiography was performed on a subset of untreated primary tumors (n=5) and compared with IHC staining for PARP-1 on sequential sections. This revealed a close spatial correspondence between elevated PARP-1 expression by IHC and regions of elevated [¹²⁵I]-KX1 binding radiographically. There was also a strong positive correlation between in vivo [¹⁸F]-FTT uptake and ex vivo quantitative [¹²⁵I]-KX1 autoradiography (r=0.78). Genomic analysis of HRD in all tumors is pending and will be reported.

Conclusion: Initial analyses support the ability of [¹⁸F]-FTT to visualize and measure PARP-1 expression in breast cancer. This is the first step toward developing an imaging companion diagnostic to help guide PARP inhibitor treatment in breast cancer. Ongoing studies are expanding upon these results, testing the extent to which expression of PARP-1 by [¹⁸F]-FTT can predict response to PARP inhibitors and measure target engagement during therapy.
Relationship between FDG-uptake and expression level of PD-L1 in primary ER positive/HER2 negative breast cancer

Tomoko Hirakata¹, Takaaki Fijii¹, Kyoichi Kaira¹, Sasagu Kurozumi¹, Ayaka Katayama², Rina Yajima¹, Sayaka Obayashi¹, Yuko NaKawazakij, Shoko Tokuda¹, Keiko Yanai¹ and Ken Shirabe¹. ¹Gunma University, Maebashi, Gunma, Japan and ²Diagnostic Pathology, Gunma University, Maebashi, Gunma, Japan.

Background: ¹⁸F-Fluorodeoxyglucose-positron emission tomography (FDG-PET) is used to evaluate the glucose metabolic rates of cancers. Several studies have reported that high FDG uptake is predictive of poor prognosis and aggressive features in patients with breast cancer (BC). FDG-uptake is influenced by many factors including inflammation. In this study, we investigated the relationship between FDG uptake and immunological factors, including degrees of stromal tumor-infiltrating lymphocytes (TILs), CD8 and programmed cell death ligand 1 (PD-L1) in ER positive/HER2 negative (ER+/HER2-) BC. No published study, to our knowledge, has assessed the association between FDG uptake and PD-L1 in BC cases, even though both represent prognosis.

Methods: Invasive carcinoma tissues of 79 ER+/HER2- BC patients who underwent surgery without preoperative therapy were examined. PD-L1, CD8 and TILs expression were evaluated by immunohistochemically (IHC) method. The evaluation of PET was determined by standardized uptake value max (SUVmax). Multivariate linear regression analysis, including expression of PD-L1, CD8 and TILs, was performed to identify independent variable correlation with SUVmax.

Results: Among the 79 ER+/HER2- BC (T1-4, N0-2, M0) patients, the analysis revealed that PD-L1 (P=0.005), lymphovascular invasion (P=0.011), large tumor size (P=0.001), lymph node metastasis (P=0.010), and high nuclear grade (P=0.011) and premenopausal status (P=0.014) were significantly associated with high SUVmax in the primary tumor. To define predictive value for the expression of PD-L1, SUVmax cut offwas determined using receiver operating characteristic (ROC) analysis; low (<3.0) and high (≥3.0). Among the 30 cases with high SUVmax, 10 cases (33.3%) had PD-L1 positive expression in the primary tumor, while only 2 (4.1%) of the 49 cases with low SUVmax had PD-L1 positive expression in the primary tumor.

Conclusions: The present study demonstrated that the finding of preoperative FDG uptake is associated with the expression of PD-L1 in ER+/HER2- BC. In light of our results, FDG uptake may be predictive of the expression of PD-L1 and may be reflective of immunological features as well as prognostic features among patients with ER+/HER2- BC.
Non-invasive estrogen receptor assessment by $[^{18}F]$-fluorestradiol(FES)-PET or circulating tumor cells predicts receptor status in patients with metastatic breast cancer

Bertha Eisses¹, Lindsay Angus², Bert van der Vegt¹, Anieta M Sieuwerts², Jaco Kraan², John WM Martens², Andor WJM Glaudemans¹, Adrienne H Brouwers¹, Otto S Hoekstra³, Wim Oyen⁴, Jasper Emmering⁵, Sophie Gerrits⁶, C Willemien Menke-van der Houven van Oordt⁷, Eline Boom⁸, Carla ML van Herpen⁹, Agnes Jager², Stefan Sleijfer², Elisabeth GE de Vries¹ and Carolien P Schröder¹.

¹University Medical Center Groningen, Groningen, Netherlands; ²Erasmus MC Cancer Institute, Rotterdam, Zuid-Holland, Netherlands; ³CCA-Amsterdam University Medical Centers - Location VUMC, Amsterdam, Noord-Holland, Netherlands and ⁴Radboud University Medical Center, Nijmegen, Gelderland, Netherlands.

Introduction: Estrogen receptor (ER) expression largely determines the therapy choice for patients diagnosed with metastatic breast cancer (MBC). Given potential conversion of ER-status, the current golden standard for ER assessment is by immunohistochemistry (IHC) on metastatic tissue. Since a biopsy is cumbersome and sometimes not feasible, ER-status assessments by means of $[^{18}F]$-fluorestradiol (FES)-PET or circulating tumor cells (CTCs) might be potential alternatives. We hypothesize that FES-PET or CTCs can determine ER status in patients with MBC, in a more efficient and patient friendly way than IHC.

Methods: In the Dutch multicenter IMPACT-MBC trial (NCT01832051) patients with non-rapidly progressive MBC at first presentation, regardless of subtype, underwent extensive molecular imaging (including FES-PET, $[^{89}Zr]$-trastuzumab-PET and serial $[^{18}F]$-fluorodeoxyglucose (FDG)-PET), a metastasis biopsy and blood sampling to obtain a whole body molecular profile of their disease. ER-status on the metastasis biopsy was evaluated by IHC and considered positive if $\geq 10\%$ of the tumor cells showed ER expression. The FES-PET was considered positive when the maximum standardized uptake value ($SUV_{\text{max}}$) of at least one lesion was $\geq 1.5$. Reverse transcription polymerase chain reaction was used to quantify the $ESR1$ expression in CTCs. ER-positivity was defined as an $ESR1$ mRNA $\Delta Cq$ level $\geq -7.86$, corrected for background healthy donor blood signal, only in samples with $\geq 5$ CTCs/7.5ml and a sufficient mRNA signal of reference and epithelial genes. Sensitivity, specificity, positive and negative predictive values were calculated (PPV and NPV).

Results: From 178 patients of 201 evaluable patients both metastasis IHC and FES-PET could be assessed. 129 of these 178 patients had an IHC ER positive metastasis (72%) and 133 patients had a positive FES-PET (75%). The PPV and NPV for IHC by FES-PET were 91% and 82%, respectively. From 54 of the 178 patients, blood samples contained sufficient CTCs for $ESR1$ analysis, allowing combined assessment of IHC, FES-PET and CTCs. ER positive CTCs were present in 45 patients (83%).

Conclusion: In newly diagnosed patients with MBC, ER-status in metastatic lesions could be predicted by means of non-invasive FES-PET scan or CTCs. Prediction was most optimal with FES-PET compared to CTCs, and combining FES-PET with CTCs did not essentially improve this. Furthermore, CTCs were not detectable in most of these patients with non-rapidly progressive MBC, limiting their applicability for the present purpose. However, as CTC assessment is most patient friendly, CTCs might be considered as first step in determining MBC ER-status. If ER positive CTCs are detected, ER positive disease is very likely; if no- or ER negative CTCs are detected, MBC ER-status needs to be further assessed by means of tissue confirmation or FES-PET.

**Background:** The histology and pattern of spread in lobular breast cancer has presented challenges in estimating extent of disease and identifying treatment options. ¹⁸F-FES is an estrogen analogue PET imaging tracer which measures tumor ER expression at multiple tumor sites simultaneously and predicts response to endocrine therapy. We analyzed FES-PET and FDG-PET SUV uptake in patients with metastatic lobular and ductal carcinoma to identify sites of tumor and responsiveness to therapy.

**Methods:** We retrospectively reviewed FES and FDG SUV uptake between ER+ lobular (n = 36) and ductal (n= 173, including 6 men) metastatic breast cancer patients enrolled in various institutional studies. Up to 3 lesions in each patient were evaluated by FES SUVmax and/or FDG SUVmax for a total of 475 lesions in FES images and 462 lesions in FDG images. Classification into three categories (low FDG, high FDG/high FES, and high FDG/low FES) was generated using recursive portioning with 5-fold internal cross validation. Using a Pearson Chi-squared test, we compared degree of uptake in FES and FDG between lobular and ductal carcinomas. We used linear mixed effects model to assess association of FES SUL³mean (Lean body mass adjusted SUV) and FDG SUL³max with histology. Overall survival (OS), from time of FES-PET scan to death, and progression free survival (PFS) was evaluated between classification groups in both histologies using Kaplan-Meier curves and Cox model.

**Results:** In patients with metastatic breast cancer, 72 patients had low FDG, 96 had high FES/high FDG, and 41 with high FES/low FDG. Lobular lesions tended to have a higher proportion of patients in the risk group with lower FDG (42% vs 33%) and a lower proportion in the risk group with high FDG/low FES (11% vs 21%) but the difference was not statistically significant (p = 0.32). Mean (range) FES SUL³mean and FDG SUL³max respectively for ductal was 1.38 (0.10, 6.7) and 3.17 (0.88, 12.26) and for lobular was 1.42 (0.34, 3.43) and 3.13 (1.04, 13.87). There was no significant difference between in FES SUL³mean and FDG SUL³max between histologies. Following FES-PET imaging, patients with lobular carcinomas and low FDG demonstrated a higher median survival time (7.7 years) compared to high FDG/low FES (4.3 years) and high FDG/high FES (2.6 years). Similarly, patients with ductal carcinomas and low FDG had an improved median survival time (5.6 years) compared to both high FDG/high FES (2.9 years) and high FDG/low FES (2.5 years). However, the interaction between histology and the FDG/FES classifications was not significant (p = 0.86). Across a variety of tumor sites, lobular histology can be detected by both FES and FDG with no difference between the imaging modalities.

**Conclusions:** In the metastatic setting, quantitative FES and FDG can be used to discriminate indolent and aggressive phenotypes in both lobular and ductal breast cancer. A greater proportion of lobular carcinoma lesions had higher FES/low FDG and would be anticipated to be more sensitive to endocrine therapy. Further prospective trials are needed to confirm the utility of FES to stage extent of disease in metastatic breast cancer.
[18F]Fluciclovine PET tracks cellular glutamine pool size in breast cancer and changes in response to metabolic inhibition

Jianbo Cao1,2, Hoon Choi1, Austin Pantel1, Daniel Kranseler1, Hsiaoju Lee1, David Mankoff1 and Rong Zhou1. 1University of Pennsylvania, Philadelphia, PA and 2Medical College, Xiamen University, Xiamen, Fujian, China.

Background: Some forms of triple negative breast cancer (TNBC) rely on glutamine (Gln) metabolism for survival and growth (1), therefore, targeting this metabolic pathway provides a viable strategy for managing TNBC. Drugs that inhibit glutaminase (GLS), a key enzyme of glutaminolysis, are being developed (1,2). [18F]Fluciclovine is a PET imaging agent that enters/exports cells via glutamine transporters and undergoes minimal metabolism. Therefore, we hypothesize, that akin to our prior work with [18F]fluoroglutamine (3), the distribution volume (VT) of fluciclovine obtained from dynamic PET can be used to estimate the cellular glutamine level (pool size) and to mark the effect of pharmacological inhibitors of tumor glutaminase (GLS). We tested this hypothesis in human TNBC and ER+ breast cancer xenograft exhibiting a high and low GLS activity, respectively.

Methods: To make [18F]fluciclovine preparation suitable for mouse imaging, citrate in the formulation was removed and replaced with PBS by eluting through a column (Bio-Rad). Cellular uptake was performed in the presence and absence of Gln transporter inhibitors and GLS inhibitor. In vivo dynamic PET imaging were performed on mice bearing HCC1806 (TNBC) and MCF-7 (ER+ BC) xenografts. Dynamic PET images were analyzed by Logan Plot (PMOD) to estimate VT.

Results: Cellular uptake of [18F]fluciclovine in HCC1806 and MCF-7 cells were sensitively inhibited by cold glutamine (Gln) and GPNA (a pharmacologic inhibitor of ASCT-2), confirming that the uptake is mediated by Gln transporters. The peak uptake in MCF-7 cells was 5-fold higher than HCC1806. In mouse models, VT from in vivo [18F]Fluciclovine PET in MCF-7 tumor is 1.4-fold of HCC1806. These data are consistent with a higher cellular Gln pool size in MCF-7 as the result of its lower GLS activity. After inhibition of tumor GLS activity, VT of [18F]fluciclovine in HCC-1806 tumors was increased by 56% from baseline values (n=2), whereas VT in MCF-7 tumors decreased 1% after treatment (n=2). Only a small change of FDG PET signal (5% decrease, n=5) was detected in TNBC tumors after GLS inhibitor treatment.

Discussions: These data suggest that VT obtained from [18F]fluciclovine PET is sensitive to changes of the Gln pool size induced by GLS inhibition whereas FDG PET is not. Since the Gln pool size is inversely related to the GLS activity, increased VT is consistent with the increased intracellular Gln level when metabolic conversion of Gln to glutamate by GLS is inhibited. Our results suggest that [18F]fluciclovine, an imaging agent approved for prostate cancer imaging, may be useful for assessing glutamine pool size in breast cancer and changes in response to GLS inhibition

Support: R21CA198563, R01CA211337, and Komen SAC130060. We thank Blue Earth Diagnostics for supplies of [18F]fluciclovine.

Use of $^{64}$Cu-DOTA-trastuzumab positron emission tomography (PET) to predict response to ado-trastuzumab emtansine (TDM1)

Joanne E Mortimer¹, James R Bading¹, Paul Frankel¹, Lusi Tumyan¹, Tri T Tran¹, Russell C Rockne¹, Jack E Shively¹, Niki Gidwaney¹, Jinh Park¹ and David M Colcher¹. ¹City of Hope, Duarte, CA.

**Background:** We have demonstrated that $^{64}$Cu-DOTA trastuzumab is an effective PET imaging agent for HER2 positive breast cancer and are now seeking to evaluate the methodology for prediction of response and benefit to ado-trastuzumab emtansine (TDM1) in women with metastatic disease.

**Methods:** Patients with metastatic breast cancer were eligible if they had biopsy confirmed HER2 + disease, at least 1 site of metastasis 2.0 cm or larger outside the biopsy site, and were to receive TDM1 as therapy. Pretreatment staging included $^{18}$F-FDG/PET. Prior to injection of $^{64}$Cu-DOTA-trastuzumab, patients received 45 mg of cold trastuzumab to reduce liver uptake. PET-CT scans were obtained at 21-25 h and 47-48 h over fields of view chosen in reference to $^{18}$F-FDG scans. TDM1 was administered at a dose of 3.6 mg/kg every 3 weeks. Restaging $^{18}$F-FDG/PET was performed every 2 cycles, and response to therapy was determined by PERCIST criteria. The radiolabel uptake was measured in terms of maximum voxel standardized uptake value (SUV$_{\text{max}}$).

**Results:** Ten women enrolled on study and are evaluable for response; three continue on TDM1 for 22-40 months and four patients remained on treatment for at least 1 year. The median age was 54.5 years (48-83 years); seven received prior trastuzumab-containing chemotherapy 3 wks to 55 months prior to study entry. HER2 was positive by IHC in 5 and by FISH in 5 (3 were 2+ by IHC; 1 was 1+ and 1 indeterminate). Complete or partial metabolic response was observed in 5 patients. Patients had their average SUV$_{\text{max}}$ on $^{64}$Cu-DOTA trastuzumab PET (aSUV$_{\text{max}}$) assessed in addition to individual assessments on up to 8 lesions on both Day1 and Day2. The mean aSUV$_{\text{max}}$ was (6.3, 8.8) for responding patients and (4.4, 5.2) for non-responders (day1, day2). The difference between responders and non-responders on Day1 aSUV$_{\text{max}}$ was marginally significant (p=0.06), but significant on Day2 (p=0.04). The three highest aSUV$_{\text{max}}$ on both day1 and day2 were three of the four patients with PFS>1 year. Data on the relationship of $^{64}$Cu-DOTA trastuzumab PET to IHC and FISH, and individual lesion SUV$_{\text{max}}$ including evidence suggesting a potential threshold effect will be presented.

**Conclusions:** In women with biopsy confirmed HER2 positive metastatic disease, $^{64}$Cu-DOTA-trastuzumab PET imaging is predictive for response to TDM1.
KEYNOTE-173: Phase 1b multicohort study of pembrolizumab (Pembro) in combination with chemotherapy as neoadjuvant treatment for triple-negative breast cancer (TNBC)

Peter Schmid¹, Yeon Hee Park², Eva Muñoz-Couselo³, Sung-Bae Kim⁴, Joohyuk Sohn⁵, Seock-Ah Im⁶, Esther Holgado⁷, Theodoros Foukakis⁸, Sherko Kuemmel⁹, Rebecca Dent¹⁰, Lina Yin¹¹, Yu Ding¹¹, Konstantinos Tryfonidis¹¹ and Javier Cortés³.

¹Centre for Experimental Medicine, Barts Cancer Institute, London, United Kingdom; ²Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; ³Vall d’Hebron Institute of Oncology (VHIO), Barcelona, Spain; ⁴Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; ⁵Yonsei University College of Medicine, Seoul, Republic of Korea; ⁶Seoul National University College of Medicine, Seoul, Republic of Korea; ⁷Ramon y Cajal University Hospital, Madrid, Spain; ⁸Radiumhemmet, Karolinska University Hospital, Stockholm, Sweden; ⁹Kliniken Essen-Mitte, Essen, Germany; ¹⁰National Cancer Centre, Singapore, Singapore and ¹¹Merck & Co., Inc., Kenilworth, NJ.

Background: TNBC has poor outcome and limited therapeutic options. Pembro monotherapy demonstrated antitumor activity and acceptable safety in metastatic TNBC. KEYNOTE-173 (NCT02622074) is a 6-cohort, phase 1b study of different doses and schedules of platinum and taxanes in combination with pembro as neoadjuvant treatment in patients (pts) with locally advanced TNBC.

Methods: Eligible pts were women aged ≥18 y with newly diagnosed, locally advanced, previously untreated TNBC. In all cohorts, patients received single pembro 200 mg administration on day 1 of cycle 1. Cycles 2-5 included pembro 200 mg with either nab-paclitaxel 125 mg/m² QW (cohort A), nab-paclitaxel 100 mg/m² QW plus carboplatin AUC6 Q3W (cohort B), nab-paclitaxel 125 mg/m² QW plus carboplatin AUC5 Q3W (cohort C), nab-paclitaxel 125 mg/m² QW plus carboplatin AUC2 QW (cohort D), paclitaxel 80 mg/m² QW plus carboplatin AUC5 Q3W (cohort E) and paclitaxel 80 mg/m² QW plus carboplatin AUC2 QW (cohort F) followed by doxorubicin 60 mg/m² Q3W and cyclophosphamide 600mg/m² Q3W with pembro 200 mg Q3W in all cohorts (Cycles 6-9) prior to surgery. Breast MRI was performed at screening and after cycles 5 and 9. Dose-limiting toxicities (DLTs) were assessed during cycles 1-3 and 6-7. Dose levels were deemed toxic if ≥3 of the first 6 pts or ≥4 of 10 pts had DLT. Primary end points were safety and recommended phase 2 dose (RP2D). Key efficacy end points were pCR (ypT0/Tis ypN0, or ypT0 ypN0), objective response rate (ORR) based on RECIST v1.1 as assessed by investigator, event-free survival (EFS), and overall survival (OS).

Results: 60 pts were enrolled by 5-31-18 (10/cohort): median age, 48.5 y (range 26-71); most had ductal histology (83.3%), T2/T3 (88.3%) and nodal involvement (66.7%). 22 pts had DLTs (2, A; 4, B/F; 6, C/D); most common was febrile neutropenia (9 pts: 1, A; 2, B/C; 4, D). The most common G3 TRAEs were neutropenia (73%), febrile neutropenia (22%), anemia (20%) and thrombocytopenia (8%). 18 pts had immune-related AEs; most common were G2 hypothyroidism (4 pts), G1 hyperthyroidism (3 pts), G3 colitis (2 pts), and G3 rash (2 pts). 11 pts discontinued pembro due to TRAEs (1, A/B/E; 4, D/F). The overall pCR rate (ypT0/Tis ypN0) was 60% (90% CI 30-85). ORR was 100% (74-100) in B/C, 90% (61-100) in D/F, 80% (49-96) in A and 70% (39-91) in E. At a median follow-up of 19.6 mo, EFS rate at 12 mo was 100% in B/C/E/F, 90% (58-98) in D, and 80% (49-93) in A. EFS rate at 12 mo was 100% and 88% for pts who did and did not achieve pCR (71-95).

Conclusion: Pembro+chemo as TNBC neoadjuvant therapy results in promising antitumor activity with manageable toxicity. Results support the ongoing KEYNOTE-522 trial.
Durability of clinical benefit with niraparib + pembrolizumab in patients with advanced triple-negative breast cancer beyond BRCA: (TOPACIO/Keynote-162)

Shaveta Vinayak1, Sara M Tolaney2, Lee Schwartzberg3, Monica Mita4, Georgia McCann5, Antoinette R Tan6, Andrea Wahner Hendrickson7, Andres Forero8, Carey Anders9, Gerburg Wulf10, Patrick Dillon11, Filipa Lynce12, Corrine Zarwan13, John Erban14, Anniina Färkkilä15, Yinghui Zhou15, Nathan Buerstatte15, Julie R Graham15, Sujata Arora15, Bruce Dezube15 and Melinda L Telli16.

**Background:** PARP inhibitor (PARPi) monotherapy has previously demonstrated clinical activity only in patients with a germline BRCA mutation (BRCAmut), while single-agent anti-programmed cell death protein 1 (PD-1) therapy has achieved response rates of only 5–20% in advanced triple-negative breast cancer (TNBC). In preclinical studies, PARP inhibition enhanced anti-tumor immunity, increased infiltration of proliferating CD8+ T cells, and synergized with anti-PD-1 agents in BRCA wildtype (wt) tumors. TOPACIO is a fully enrolled, phase I/II trial of niraparib + pembrolizumab (pembro) in advanced TNBC. This combination achieved 28% objective response rate (ORR) and 50% disease control rate (DCR) in evaluable patients. Although activity was highest in patients with BRCAmut (ORR=60%; DCR=80%), durable clinical benefit was also observed in patients without BRCA mutations. In this study, we conducted exploratory biomarker analyses to evaluate their potential correlation with durable clinical benefit (any complete response [CR] or partial response [PR] regardless of duration or stable disease [SD] for ≥16 weeks) beyond BRCA mutations.

**Method:** ORR was assessed by RECIST v1.1. Duration of disease control (DDC) was defined as time from first dose of study treatment to radiologic disease progression or death. Tumor mutational status of homologous recombination repair (HRR) and other DNA damage repair (DDR) pathway genes was determined using an NGS panel. Immunoprofiling was conducted using NanoString IO360 panel complimented with 30 DNA repair spike-ins. Tumor immune micro-environment was characterized using multiplex immuno-fluorescence (CycIF). PD-L1 status was determined using the Agilent/DAKO 22C3 IHC clinical trial assay.

**Results:** Of 46 evaluable patients, 20 achieved durable clinical benefit (any CR/PR or SD≥16 weeks) with niraparib + pembro combination, of which 8 were tumor BRCA wild type (wt), and 1 was BRCA unknown. Of the 9 BRCAwt/unknown patients, 5 had deleterious mutations in HRR/DDR pathway genes, whereas the remaining 4 had no mutations (HRR/DDR wt). Mutations that were associated with response include CHEK1 (CR; DDC=10.3 mos), ATR (CR; DDC=6.4 mos), PALB2 (PR; DDC=3.5 mos), BLM (SD; DDC=8.1 mos), and NBN/RAD51C (SD; DDC=3.7 mos). Of 4 patients that had no identified mutations (HRR/DDR wt), 1 patient had CR; DDC=10.3 mos, and the remaining 3 patients had SD with DDC ranging from ∼4-8 mos. Of note, all 4 HRR/DDR wt patients were also PD-L1-negative.

Conclusion: Patients with mutations beyond *BRCA* achieved durable clinical benefit with niraparib + pembro treatment; five of these patients had DDC >6 mos. Mutations in genes that are associated with the HRR/DDR pathway appear to confer sensitivity to niraparib + anti-PD1. Additional translational analyses, including immunoprofiling and CycIIF, will be presented.

Characterization of high TIL breast cancers reveals a prognostic and functionally distinct tissue-resident memory subpopulation

Peter Savas¹, Balaji Virassamy¹, Chengzhong Ye²,³,⁴, Agus Salim³,⁵, Christopher P Mintoff¹, Franco Caramia¹, Roberto Salgado⁷, Zhi L Teo¹, Sathana Dushyanthen¹, Ann Byrne¹, Stephen J Luen¹, Stephen B Fox¹, Terence P Speed²,³, Laura K Mackay²,³, Paul J Neeson¹ and Sherene Loi¹. ¹Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia; ²University of Melbourne, Parkville, Victoria, Australia; ³Walter & Eliza Hall Institute of Medical Research, Melbourne, Victoria, Australia; ⁴Tsinghua University, Beijing, Haidian Qu, China; ⁵La Trobe University, Melbourne, Victoria, Australia; ⁶Peter Doherty Institute for Infection and Immunity, Melbourne, Victoria, Australia and ⁷GZA Ziekenhuizen, Antwerp, Belgium.

Background: Tumor infiltrating lymphocytes (TILs) assessed via light microscopy are prognostic and predictive in the early stage and advanced triple negative and HER2-amplified breast cancer (BC). Higher TILs can also identify patients more likely to benefit from anti-PD-1 therapy. In this study we interrogated T cell subsets that comprise high TILs to determine if distinct subpopulations are key mediators of anti-tumor immunity.

Methods: We characterised TILs with a focus on CD3⁺ T cells in 129 primary and metastatic BC samples using flow cytometry, bulk RNASeq on flow sorted T cell populations, multiplex immunohistochemistry and microdroplet based single cell 3’ mRNA sequencing on the 10X Genomics Chromium platform. Cell type specific gene expression signatures were determined from differential expression between putative T cell subpopulations. These signatures were investigated in clinical cohorts, including trial cohorts treated with pembrolizumab.

Results: High TIL Infiltrates consisted primarily of CD3⁺ T cells, with both CD8 and CD4 populations. Unsupervised clustering of single cell sequencing identified 9 CD8 and CD4 subpopulations with distinct gene expression profiles. In addition to Tregs and CD8 effector memory (TEM) T cells, we found a CD8⁺ tissue resident memory (TRM) population expressing greater levels of T-cell checkpoints and cytotoxic markers compared to effector memory cells. In 2 primary tumours and 1 liver metastasis, bulk RNASeq of flow sorted TEM and TRM corroborated the single cell mRNASeq results. T cell receptor profiling (TCR) in the 3 samples found non-overlapping repertoires in the 2 primary tumours, but overlap in one metastatic lesion, suggesting divergent developmental origins in the breast, but the potential for nascent TRM differentiation in a metastatic niche. Clustering of these TCRs suggested differing antigen specificities between TRM and non-TRM CD8 T cells. Using Metabric data, the CD8 TRM gene expression signature was prognostic for disease free survival (DFS) in primary TNBCs (n=329, log-rank p=0.003), and was able to further stratify cases with high and low CD8A expression for DFS (log-rank p = 0.03). The CD8 TRM signature was enriched in baseline tumour samples of responders (n = 9) compared with non-responders (n=36) in 45 patients with metastatic melanoma treated with T cell checkpoint blockade (p < 0.0001). Additional single cell sequencing data with TCR sequencing will be combined with these initial results, and an independent data set of single cell mRNASeq and TCR Seq on CD3⁺ BC TILs will be used to confirm our findings. Cell type specific signatures will be explored in additional clinical cohorts including KEYNOTE-086, and presented at the meeting.

Conclusion: Using single cell profiling of the immune microenvironment in BC we demonstrate that high TIL BCs contain multiple T cell subpopulations with different functional and prognostic significance. Our approach identified a CD8 TRM population with a distinct gene expression profile and strong expression of key immune checkpoints likely representing the presence of true tumor specific immunity. This population may be a key target of immune checkpoint blockade.
An open-label, phase II basket study of olaparib and durvalumab (MEDIOLA): Updated results in patients with germline BRCA-mutated (gBRCAm) metastatic breast cancer (MBC)

Susan M Domchek, Sophie Postel-Vinay, Seock-Ah Im, Yeon Hee Park, Jean-Pierre Delord, Antoine Italiano, Jerome Alexandre, Benoit You, Sara Bastian, Matthew G Krebs, Saiama Waqar, Mark Lanasa, Helen K Angell, Mei Tang, Christopher Gresty, Laura Opincar, Pia Herbolsheimer and Bella Kaufman.

Background: Olaparib (Lynparza®) is approved for the treatment of gBRCAm HER2-negative MBC based on the OlympiAD study results. Olaparib-induced DNA repair defects may attract tumor-infiltrating lymphocytes, upregulate programmed cell death ligand-1 (PD-L1) and release tumor neo-antigens upon cell death. Here, the objective was to assess the efficacy and safety of olaparib in combination with durvalumab (Imfinzi), a PD-L1 agent, in gBRCAm HER2-negative MBC (NCT02734004).

Methods: Patients (pts) with HER2-negative, gBRCAm MBC were eligible; prior platinum therapy without disease progression was allowed. Pts received olaparib 300 mg tablet BID for a 4-wk run-in, followed by a combination of olaparib 300 mg BID and durvalumab 1.5 g IV q 4 wks. The combination was continued until progressive disease by RECIST 1.1. Tumor assessments were done at baseline, 4 wks, and every 8 wks thereafter. The primary endpoints were disease control rate (DCR) at 12 wks, safety and tolerability. The secondary endpoints included DCR at 28 wks, objective response rate (ORR), duration of response (DoR), progression-free survival (PFS), overall survival (OS) and a biomarker analysis. A Bayesian predictive probability design was used for the statistical analysis of the primary endpoint.

Results: Thirty-four pts were included in the safety, and 32 pts in the efficacy analysis. At data cut-off (DCO) on 30 Mar 18, the 12-wk DCR was 81% (90% CI: 66%, 92%) and 28-wk DCR 47% (90% CI: 32%, 63%). The ORR for the overall cohort was 56% (95% CI: 38%, 74%), with 1 (3%) complete response (CR), 17 (53%) partial response (PR), 8 (25%) stable disease (SD), and 6 (19%) progressive disease (PD). Median DoR was 9.2 months (interquartile range, 5.5 to 12.9 months). First- and second-line pts showed higher response rates (70% and 73%, respectively) compared to pts with 3 or more lines of prior chemotherapy (27%) (Table 1). The median PFS for the overall cohort was 6.7 months (95% CI of 4.6, 11.7 months). With median follow-up of 14.5 months, the median OS has not been reached. At the time of DCO, 8 (25%) pts remained on combination therapy. The most common Grade 3 or 4 adverse events reported were anemia (11.8%), neutropenia (8.8%), and pancreatitis (5.9%). Efficacy and safety results with longer follow-up will be presented. Biomarker analysis on CD3, CD8 and PD-L1 expression in the archival tissue and in paired biopsies obtained at baseline and after olaparib monotherapy run-in, will also be presented.

Conclusions: The addition of durvalumab to olaparib showed promising activity with the ORR in the early line gBRCAm MBC pts, comparing favorably with olaparib monotherapy (OlympiAD) (>70% in 1–2L MEDIOLA vs 60% overall in OlympiAD). In addition, the median DoR appeared longer with the combination (9.2 months in MEDIOLA vs 6.4 months in OlympiAD). Approximately one-third of the pts in MEDIOLA were heavily pretreated (3L+) and as expected, the ORR was lower in these pts. Due to the small number of pts, these results warrant confirmation of activity in the early-line setting. Further MBC cohorts are in development.

Best responses by line of therapy

Pre-therapeutic PD-L1 expression and dynamics of Ki-67 and gene expression during neoadjuvant immune-checkpoint blockade and chemotherapy to predict response within the GeparNuevo trial

Bruno V Sinn¹, Sibylle Loibl², Thomas Karn³, Michael Untch⁴, Catarina A Kunze¹, Karsten E Weber², Denise Treue¹, Kai Wagner⁵, Claus A Hanusch⁶, Frederick Klauschen¹, Peter A Fasching⁷, Jens Huober⁸, Dirk-Michael Zahm⁹, Christian Jackisch¹⁰, Jörg Thomalla¹¹, Jens-Uwe Blohmert¹², Marion van Mackelenbergh¹³, Kerstin Rhiemi¹⁴, Bärbel Felder¹⁵, Gunter von Minckwitz², Nicole Burchardi¹⁶, Andreas Schneeweiss¹⁷ and Carsten Denkert¹. ¹Institut für Pathologie, Charité-Universitätsmedizin, Berlin, Germany; ²German Breast Group, Neu-Isenburg, Germany; ³Klinik für Frauenheilkunde und Geburtshilfe, Universitätsklinikum, Frankfurt, Germany; ⁴HELIOS Klinikum, Berlin-Buch, Germany; ⁵Pathologie am Rotkreuzklinikum, München, Germany; ⁶Klinikum zum Roten Kreuz, München, Germany; ⁷Brustzentrum, Universitätsklinikum, Erlangen, Germany; ⁸Universitätsfrauenklinik, Brustzentrum, Ulm, Germany; ⁹SRH Wald-Klinikum, Gera, Germany; ¹⁰Sana Klinikum, Offenbach, Germany; ¹¹Praxisklinik für Haematologie und Onkologie, Koblenz, Germany; ¹²Brustzentrum, Charité-Universitätsmedizin, Berlin, Germany; ¹³Klinik für Gynäkologie und Geburtshilfe, Universitätsklinikum, Kiel, Germany; ¹⁴Zentrum Familiärer Brust- und Eierstockkrebs, Universitätsklinikum, Köln, Germany and ¹⁵Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany.

Background
In the GeparNuevo trial, the PD-L1 inhibitor durvalumab increased the rate of pathologic complete response (pCR; ypT0 ypN0) in triple-negative breast cancer if treatment started in a two-week window before neoadjuvant taxane/anthracycline chemotherapy (61 % pCR vs. 41%; p = 0.048; Loibl et al. ASCO 2018). Overall, pCR rates increased only numerically from 53 % to 44 % (p = 0.281). Herein, we aimed to evaluate the predictive value of PD-L1 immunohistochemistry in pre-therapeutic core biopsies. In addition, we identified dynamics in gene expression using repeated biopsies.

Patients and Methods
174 patients were randomized to receive durvalumab or placebo with neoadjuvant chemotherapy. In the window part, 117 patients received a single dose of durvalumab (or placebo) before chemotherapy. Core biopsies were taken at three times: pre-treatment (“A”; N=174), after the window part (“B”; N=88) and after 12 weeks of nab-Paclitaxel (“C”; N=33). PD-L1 immunohistochemistry in A-biopsies (Ventana SP263 Assay) was recorded as percentage of cells with membranous staining in tumor cells and lymphocytes (TILs). We defined a tumor as PD-L1 high if ≥ 25 % of either compartment was stained. Ki-67 was stained on all available A, B and C biopsies (MIB-1, Dako, 1:100) and recorded as the percentage of tumor cells with nuclear staining. We profiled all available biopsies with targeted RNASeq using the HTG EdgeSeq platform (Oncology Biomarker panel, 2560 genes). Sequencing (IonTorrent S5) was successful in 162 A-, 79 B- and 31 C-biopsies.

Results
PD-L1 expression was high in 24 % of A-biopsies and was predictive for pCR in the complete cohort (OR 2.561; 1.183-5.554; p = 0.017). PD-L1 status of the TILs, but not of the tumor cells, was predictive (OR 1.313; 1.040-1.656; P = 0.022). The effect was not specific for durvalumab treatment. Higher levels of Ki-67 were predictive for pCR in B- biopsies in all patients (OR 1.399; 1.053-1.858; P =0.021) and in the placebo arm, but not in the durvalumab arm. Ki-67 levels in C-biopsies were not predictive; neither was the change in Ki-67 between pre-treatment and later time points (B vs. A or C vs. A). In a differential mRNA expression analysis (A vs. B), we found seven differentially expressed genes after one dose of durvalumab. We observed strong effects on gene expression after taxane treatment (A vs. C), but no significant difference according to treatment. These genes were associated with biological processes involved in therapy response. The pre-treatment levels of 12 of 69 markedly differentially expressed genes were associated with worse response to chemotherapy.

Conclusion
In A-biopsies, PD-L1 in TILs was predictive for response, and in B-biopsies, Ki-67 was predictive, but neither marker could specifically predict response to durvalumab. We observed limited effects of a single half-dose of durvalumab on global gene expression, but could identify substantial differential expression after taxane treatment. The evaluation of gene expression dynamic offers a promising approach for the identification of resistance-associated markers. The study was financially supported by AstraZeneca and Celgene.
Comprehensive profiling of poor-risk paired primary and recurrent triple-negative breast cancers reveals immune phenotype shifts

Yuan Yuan¹, Susan E Yost¹, Ching-Wei Chang², Kathryn E Yoh², Radia M Johnson², Daniel Schmolze¹, Jackson Liang² and Katherine E Hutchinson². ¹City of Hope National Medical Center, Duarte, CA and ²Genentech, South San Francisco, CA.

Background: Prognosis for triple-negative breast cancer (TNBC) patients remains poor, due in part to the lack of effective targeted therapies in the advanced setting. Emerging clinical data indicates reduced efficacy of immune checkpoint inhibitors in heavily pre-treated TNBC, but the underlying mechanisms are poorly understood. To better understand the immune phenotypic evolution of paired TNBCs, we studied the genomic and transcriptomic profiles of tumors from patients undergoing treatment for TNBC.

Methods: We analyzed primary and recurrent TNBCs from 55 poor-risk patients, including 44 paired primary-metastatic samples and 11 paired metastatic tumors. FoundationOne® and RNAseq was successful on 89 specimens and 97 specimens, respectively. In addition to somatic alterations, FoundationOne® provided tumor mutational burden (TMB). From RNAseq, we ascertained the TNBC molecular subtypes, and the mRNA expression of immune-related genes. Stromal tumor-infiltrating lymphocytes (stromal TILs), recurrence-free survival, and overall survival were also studied.

Results: From FoundationOne® sequencing, a mutational landscape typical of TNBCs was observed across both primary and recurrent disease specimens, with TP53 mutated in 82.0% of specimens, and BRCA1 and BRCA2 mutated in 4.5% and 16.9% of specimens, respectively. Sample profiles revealed minimal shifts in copy number alterations and TMB over time, however, notable TNBC subtype shifts were observed between primary and recurrent tumors. These included an increase in the Lehmann/Pietenpol-defined basal-like 1 phenotype (BL1, 12.8% to 20.9%), an increase in the mesenchymal phenotype (M, 12.8% to 20.9%), and a significant decrease in the immunomodulatory phenotype (IM, 27.1% to 2.3%). Similarly, tumors exhibited a downward shift in gene expression delineating the Burstein-defined basal-like immune-activated phenotype (BLIA, 37.0% to 14.3%). Composite expression of immunomodulatory gene signatures representative of Th1/Th2 responses, IFNγ-related inflammation, M1/M2 macrophage activation and suppression, etc., was decreased in the recurrent tumors compared to the primaries (p = 0.01), and histopathology-derived percent stromal TILs were significantly decreased in the recurrent TNBCs (p = 0.02). However, higher stromal TILs (≥30%) were not associated with improved overall survival when measured in primary specimens (p = 0.15), or with the time from relapse to death when measured in recurrent specimens (p = 0.65) in this cohort of immunotherapy-naïve patients.

Conclusion: In this retrospective study of paired TNBCs, significant transcriptomic phenotype shifts were observed as patients progressed, while only minor genomic shifts were seen. Selective immune profiling showed significantly reduced TILs and immune-activating gene expression signatures in recurrent TNBCs, which may explain the lack of efficacy of immunotherapeutic agents in heavily pretreated TNBCs. Further studies are ongoing to understand the proteomic landscape shifts in TNBCs over time and to identify novel targeted agents appropriate for recurrent disease.
Neoadjuvant chemotherapy alters the genomic landscape and immune microenvironment of breast cancers

Zhengyan Kan¹, Samir Lal¹, Ying Ding¹, Jeong Eon Lee², Soo-Hyeon Lee¹, Se Kyung Lee², Jong Han Yu², Yoon-la Choi², Seok Won Kim², Seok Jin Nam², Ji-Yeon Kim², Sripad Ram¹, Eric Powell¹, Keith Ching¹, Soo Youn Cho², Vinicius Bonato¹, Shibing Deng¹, Woong-Yang Park², Paul Rejto¹, Jadwiga Bienkowska¹ and Yeon-Hee Park². ¹Pfizer, San Diego, CA and ²Samsung Medical Center, Seoul, Korea.

Understanding how standard-of-care drug treatments affect tumor intrinsic biology and microenvironment is critical for elucidating drug resistance mechanisms and developing better combination therapies as well as new therapies. To characterize the effects of neoadjuvant chemotherapy (NAC) on the genome, transcriptome and tumor infiltrating leukocytes (TILs), we have conducted whole exome and whole transcriptome sequencing of a large longitudinal breast cancer cohort consisting of 146 cases and 281 paired tumor samples. In total, 52 (38%) patients achieved pathologic complete response (pCR) while 85 patients (62%) had residual disease with standard chemotherapy regimen. Tumor biopsies were collected for each patient at three time points – pre-treatment, three weeks after the first cycle of anthracycline and cyclophosphamide (AC) and at the time of surgery after 3 more cycles of AC followed by 4 cycles of taxane or taxane plus Herceptin in case of HER2+ subtype. We detected 5,955 protein-altering somatic mutations affecting 4,414 genes in pretreatment samples and 502 acquired mutations in surgery samples affecting 477 genes including 19 recurrently mutated genes such as TP53 and NOTCH1. Across all subtypes, 4,346 genes were differentially expressed (DE) following NAC treatment and significantly enriched in pathways such as cell cycle, ER signaling, PI3K/mTOR, immune and metabolism. Expression-based virtual microdissection analysis indicated that NAC treatment induced an increase in the fractions of stromal and adjacent normal tissue compartment, consistent with observed reduction in tumor cellularity. To assess the NAC induced changes in the molecular landscape of these tumors, we compared molecular features including gene expression signatures, mutation prevalence and copy number alteration between three time points while adjusting for confounding effects of molecular subtype and tumor cellularity. We found that NAC induced dynamic changes in gene expression signatures associated with proliferation and immunomodulatory treatment response. We further validated the observed pattern of change in TILs through histopathology and digital imaging analyses. In pretreatment tumors, 116 genes were DE between patients with pCR vs. those with residual disease with significant enrichment in immune/inflammatory pathways. Further, pre-treatment TIL levels were found to be significantly associated with pCR, echoing previous reports in breast cancers that implicated anti-tumor immunity in mediating the efficacy of chemotherapies. Our analyses also revealed associations between NAC response and baseline genomic attributes such as genomic alterations that affect DNA damage repair pathways. Taken together, these results suggest that NAC induced a multitude of changes on the genomic landscape and immune microenvironment of breast cancers, some of which point to combination strategies with immunomodulatory therapies and therapies that target DNA damage repair.
The immunomodulatory potential of denosumab in breast cancer: results from D-BEYOND, a window of opportunity trial evaluating a RANK-ligand (RANKL) inhibitor and its biological effects in young pre-menopausal women diagnosed with early breast cancer

Bastien Nguyen1, Maetens Marion1, Roberto Salgado1, David Venet1, Peter Vuylsteke2, Laura Polastro1, Hans Wieldiers3, Philippe Simon4, Geoffrey Lindeman5, Denis Larsiomont1, Gert Van den Eynden1, Chloe Velghe1, Françoise Rothe1, Soizic Garaud1, Stefan Michiels6, Karen Willard-Gallo1, Hatem A Azim Jr7, Sherene Loi5 and Christos Sotiriou1.

Background
Breast cancer (BC) in young women has unique biology and poor prognosis. Previous reports suggest that they often express RANKL, which was also shown to play a role in mammary tumorigenesis and various immune processes. Here, we present the primary results of D-BEYOND, a window study investigating the biological activity of the RANKL inhibitor; denosumab in pre-menopausal BC patients.

Methods
D-BEYOND is a prospective, phase IIA, single-arm, multicenter study assessing the effect of denosumab on BC biology in premenopausal women with early BC (NCT01864798). Patients received two subcutaneous injections of denosumab (120mg), one week apart, followed by breast surgery. The primary endpoint was geometric mean change in tumor Ki67 assessed by immunohistochemistry (IHC). Blood, tumor and normal adjacent breast tissue were collected pre- and post-treatment. Serum levels of RANKL, OPG and CTX were assessed by ELISA. RNA was extracted from fresh-frozen tissue and RNAseq was performed. DESeq2 was used for differential expression analysis, GAGE was used for pathway analysis and CIBERSORT was used to infer immune cell subsets between pre- and post-treatment. Ki67, CD4/Foxp3 and CD4/CD8 IHC were performed on FFPE tissue to further assess the immune microenvironment. The percentage of TILs was independently evaluated by two pathologists on H&E slides. Pre- and post-treatment values were compared using a paired t-test.

Results
A total of 27 patients were enrolled in the study between October 2013 and July 2016. The median age was 45 years (range 35-51 years). Tumors of 21 patients were hormone receptor positive (77.8%), 4 were HER2 positive (14.8%) and 2 were triple negative (7.4%). No serious adverse events were reported, the most frequent non-serious adverse event being arthralgia (14.8%). After treatment, serum levels of CTX and RANKL decreased in all patients (P < 0.001) whereas OPG increased in 76.9% of patients (P = 0.009, 95% CI 0.56-0.91). There was no significant reduction of Ki67 values from baseline (geometric mean [GM] change after treatment; 0.98, 95% CI 0.76-1.26; P = 0.90). Twenty-four pre- and post-treatment tumor pairs were available for RNAseq, IHC and TILs evaluation. There was a significant increase in the percentage of stromal TILs after treatment (GM change of 1.72, 95% CI 0.00-0.91; P = 0.001). 1084 differentially expressed genes were identified and pathway analysis revealed enrichment of several immune processes. CIBERSORT revealed an enrichment of CD8+ T cells (GM change 1.72, 95% CI 1.19–2.48; P = 0.006) and a decrease of Treg cells (0.71, 95% CI 0.52–0.98, P = 0.040). These results were confirmed by IHC of CD8+ and CD4+/Foxy3+ cells (GM change 1.59, 95% CI 1.14–2.21; P = 0.008 and 0.63, 95% CI 0.49–0.83, P = 0.001, respectively).

Conclusion
Short course of denosumab did not reduce tumor proliferation rate. However, it induced a significant increase in TILs and CD8 cytotoxic T cells, while Treg infiltration decreased. These findings suggest an immunomodulatory role for denosumab in young breast cancer and that its use in combination could boost immunotherapy efficacy.
Immune parameters associated with survival in triple negative and HER2-positive breast cancer patients with 10 years of follow-up

Cinzia Solinas¹, Alexandre de Wind², Gert Van den Eynden¹, Lieveke Ameye², Soizic Garaud¹, Pushpamali De Silva¹, Anaïs Boisson¹, Gregory Noel¹, Mireille Langou Fontsa¹, Laurent Buisseret³,⁴, Evandro de Azambuja³, Prudence A Francis⁵, Angelo Di Leo⁶, John PA Crown⁷, Christos Sotiriou³,⁴, Denis Larsimont², Marianne Paesmans², Martine Piccart-Gebhart⁶ and Karen Willard-Gallo¹. ¹Molecular Immunology Unit, Institut Jules Bordet and Université Libre de Bruxelles, Brussels, Belgium; ²Institut Jules Bordet, Brussels, Belgium; ³Institut Jules Bordet and Université Libre de Bruxelles, Brussels, Belgium; ⁴Breast Cancer Translational Research Laboratory, Institut Jules Bordet, Bruxelles, Belgium; ⁵Peter MacCallum Cancer Centre, St. Vincent’s Hospital, University of Melbourne, and Breast Cancer Trials Australia and New Zealand, University of Newcastle, Melbourne, Australia; ⁶Hospital of Prato, Prato, Italy and ⁷Medical Oncology, Vincent's University Hospital, Dublin, Ireland.

The clinical utility of tumor-infiltrating lymphocytes (TIL) is actively being investigated in breast cancer (BC). It is unclear whether TIL spatial location and organization in tertiary lymphoid structures (TLS) have an impact on prognosis. Additionally, the significance of PD-1 and PD-L1 expression is being debated due to conflicting data from several studies. We hypothesize that the presence, extent and spatial location of multiple immune biomarkers, reflecting ongoing immune responses, will be consistently associated with a good prognosis in highly infiltrated BC [triple-negative (TNBC) and HER2+].

The relationship between these immune biomarkers and clinical outcome was examined in the TNBC and HER2+ cohorts of node-positive BC patients enrolled in the BIG 02-98 adjuvant phase III trial with available material for immunohistochemical (IHC) labeling (N=113 and N=136, respectively). HER2+ patients did not receive trastuzumab. Dual IHC staining was performed on full-face consecutive tissue sections. Scoring was independently performed by two pathologists, blinded to the clinical data, and included: global, intratumoral and stromal TIL and TLS, assessed on CD3/CD20 slides; the percentage and location of PD-1 and PD-L1 expression, assessed on PD-1/PD-L1 slides. TIL were considered as a categorical variable with different cut-offs used for each parameter and for each cohort (TNBC and HER2+). Invasive disease-free survival (I-DFS) and overall survival (OS) were analyzed (median follow-up: 10 years). Cox proportional hazard models were used for survival analyses.

The TNBC cohort revealed an association between global TIL and outcome [adjusted hazard ratio (HR) for I-DFS: 0.27 (0.15-0.51); OS: 0.26 (0.13-0.53)]. Similar results were observed for stromal and intratumoral TIL. PD-L1 expression within TLS was an independent predictor of OS, after adjustment for tumor size and age [HR: 0.30 (0.09-0.99)]. Multivariate analysis reveals this effect was principally driven by high stromal TIL (≥17.5% based on CD3/CD20 assessment) (χ² OS: p=0.009). In contrast, no significant prognostic associations were found in the overall HER2+ cohort. However high T cell TIL were associated with improved I-DFS and OS in the ER-/HER2+ group [I-DFS: 0.34 (0.14-0.80); OS: 0.32 (0.12-0.86)] and stromal TIL were associated with improved I-DFS in the ER+/HER2+ group [HR: 0.29 (0.09-0.94)] (univariate analyses). No significant associations between the number of TLS nor the expression of PD-1 with outcomes were observed in either cohorts.

The presence of PD-L1⁺ TLS, driven by high baseline TIL, was associated with an excellent prognosis in node-positive TNBC. This observation might reflect specific immune activities taking place in these mini lymph node-like structures adjacent to the tumor bed where specific antitumor memory immune responses could be generated. No different prognostic impact was observed when analyzing TIL spatial location. Although the statistical power of the study might be limited, in line with previous findings our data reveal that, among the immune parameters evaluated, TIL are the strongest predictor of outcome in TNBC, while PD-L1⁺ TLS could be a new and important parameter that requires further investigation.
Immune characterization of matched primary and multiple metastatic samples issued from an institutional autopsy cohort

Borbala Szekely¹, Yacine Bareche², Gert Van den Eynden³, Roberto Salgado⁴, Laurence Buisseret², Soizic Garaud², Karen Willard-Gallo², Christos Hatzis⁴, Marcell Szasz¹, Janina Kulka¹, Denis Larsimont³, Christos Sotiriou³, Lajos Pusztai⁴ and Christine Desmedt⁴. ¹Semmelweis University, Budapest, Hungary; ²Institut Jules Bordet-Université Libre de Bruxelles, Brussels, Belgium; ³Sint Augustinus, Wilrijk, Belgium and ⁴Yale, New Haven.

Introduction
While immune infiltrates have already been extensively characterized in primary tumors (P), data on breast cancer metastases (M) remains limited. To this end we quantified and qualified the immune cells in a unique cohort of multiple matched P and M samples selected from an institutional breast cancer autopsy cohort.

Patients and methods
Twenty-three patients were selected from an institutional autopsy program (Semmelweis University, Budapest, Hungary) based on matched P and M sample availability (124 samples). All samples were centrally characterized for estrogen (ER), progesterone (PR) and HER2 receptors. The primary molecular subtypes were as follows: 9 ER+/PR+/HER2-, 8 triple negative and 6 HER2+.

Ten patients relapsed ≤1 year after diagnosis and were further referred to as "early relapsers", as opposed to the remaining qualified as "late relapsers". Immunohistochemistry (IHC) was carried out against CD3/CD20 and CD4/CD8 in 21 patients (119 samples). Tumor infiltrating lymphocytes (TILs) were assessed on hematoxylin and eosin (H&E) and CD3-stained slides. Gene expression data were generated using the NanoString nCounter assay (PanCancer Immune Profiling Panel) for 11 patients (35 samples) and analyzed using the R package NanoStringQCPro. The scores from published immune gene signatures were calculated as a weighted sum of the expressions of their genes. All samples were analyzed for 22 immune cell subtypes relative abundance using CIBERSORT.

Results
TILs assessed on H&E and CD3-stained slides were weakly correlated (Rho= 0.38, p<.001). TIL levels as well as the number of tertiary lymphoid structures (TLS) were significantly lower in Ms as compared to Ps (<.001). Among the different metastatic sites, the lung was more infiltrated when considering CD3+ and CD4+ cells (p=.01 and .02, respectively). We further observed significantly higher levels of TILs, CD3+, CD4+ and CD8+ cells in the Ms but not in the Ps from late relapsers as opposed to those from early relapsers. Gene expression analyses further confirmed these observations as several immune gene signatures displayed significantly higher scores in the Ms from late compared to early relapsers. An unsupervised analysis identified 13 genes significantly differentially expressed between Ps and Ms: CSF1R, CXCL14, CYBB, IL21R, IL2RB, TNF and TNFSF15 were upregulated in Ps while BCL2L1, C7, HSD11B1, and PSMB7 were upregulated in Ms. The matched P/M CIBERSORT analyses revealed a distinct composition of immune cell types between P and M of a same patient. Apart from a potential increase in M0 macrophages, no common trait was observed in immune cell composition between the Ms from the different patients.

Conclusion
This is to the best of our knowledge the first study characterizing the immune infiltration in patients with multiple matched P and M samples. The results suggest that Ms have not only a globally lower immune infiltration as compared to Ps, but also a different immune composition. Additionally, Ms from late relapsers are more infiltrated as compared to early relapsers. The present data also uncovers not only important inter-patient but also intra-patient immune heterogeneity, which should be taken into consideration for optimal treatment decision.
In breast cancer (BC), tumor infiltrating lymphocytes (TILs), in particular CD8 T cells, have prognostic value, yet response rates to immune therapies are generally low and differ significantly across subtypes.

To define immune markers that would facilitate the identification of patient subgroups which respond to immune therapies, we assessed the quality and quantity of T cell evasive mechanisms in BC subtypes, using large gene expression datasets (microarray GSE2034/5327 and DNA/RNAseq: EGAS00001001178). To this end, we generated a 152 immune-gene signature, based on quantitative measurements of TILs. This TIL signature highly correlated with numbers of TCR reads (MIXCR, $r=0.91$, $p<0.0001$) and frequencies of activated lymphocytes (Cibersort, such as CD8 T cells, follicular helper CD4 T cells and plasma cells), whereas this signature inversely correlated with frequencies of immune suppressor cells (such as M2 macrophages, MDSCs and neutrophils). We tested this signature for its prognostic value in our cohort of 344 LNN patients, not adjuvantly treated with hormone- or chemotherapy (GSE2034/5327). Luminal A and B subtypes had low average TIL scores. Her2 and basal-like tumors had equally high TIL scores, yet an association between TIL score and survival was only observed in the Her2 molecular subtype (HR=0.24, $p<0.001$). Multi-immune parameter analysis demonstrated that Her2 BC is characterized by a high antigen load (extent of neo and cancer germline antigens) and relatively low frequencies of suppressor cells. In contrast, basal-like BC is characterized by the highest antigen load ($p=0.003$), the highest number of clonally expanded T cells ($p<0.001$), the highest frequency of immune suppressor cells ($p<0.001$), and significantly enhanced expression of co-inhibitory molecules (such as LAG3 and PD-L1). Notably, a subset of basal-like tumors had mutations in antigen presentation/processing pathways and/or lacked gene-expression of molecules involved in this pathway, suggesting selection of lesser immunogenic tumor cells. Interestingly, regardless of low antigen load, also normal-like BC had a high TIL score, yet no clonally expanded T cell clones, which suggests lack of a tumor-specific T cell response.

Collectively, these data suggest that not TIL score per se but rather the extent of immunogenicity and T cell suppressive mechanisms discriminate BC subtypes. These results point toward the requirement of different combinatorial approaches to boost the efficacy of immune therapies across BC subtypes.
Spatial mapping of the immune microenvironment in primary triple-negative breast cancer (TNBC) and association with neoadjuvant therapy response

Melinda L Telli¹, Shaveta Vinayak², Michael S Khododoust¹, Joshua J Gruber¹, James M Ford¹, Phillip Sanchez³, Nooriel Banayan³, Saeed Azimi³, Paul C Tumeh³, Aaron M Newman¹ and Ash A Alizadeh¹. ¹Stanford University School of Medicine, Stanford, CA; ²University of Washington, Seattle, WA and ³BioGraph 55, San Francisco, CA.

Background: Emerging data suggest that some patients with TNBC could benefit from the addition of immune-based therapy. This observation is in part due to the significant association between distinct tumor-infiltrating lymphocytes (TILs) and prognosis in TNBC. Efforts to comprehensively characterize the immune microenvironment of TNBCs are critically important to gain a better understanding of the immune landscape and how it influences response to both standard chemotherapy and immunotherapy. We previously assessed both stromal TILs (sTILs) and intraepithelial TILs (iTILs) from pre-treatment tumor samples from patients enrolled on a phase II study of neoadjuvant gemcitabine, carboplatin and iniparib (PrECOG 0105; NCT00813956). We found that both iTILS and sTILS significantly associated with pathologic response. Furthermore, we assessed a novel 'in silico flow cytometry' gene expression-based method, CIBERSORT, designed to assess overall immune content and deconvolute the relative levels of distinct leukocyte subsets in tumors. Specific leukocyte subsets significantly associated with pCR included activated memory CD4+ T cells, CD8+ T cells and M1 macrophages (all p<0.05). To validate these findings and further explore spatial mapping of these immune cell subsets we undertook this analysis.

Methods: We performed SPARTA - Spatial Perception And Regional Tumor Analysis - a multiplexed immunohistochemistry-based technology with data visualization and analysis modules that is designed to capture clinically relevant information about the tumor microenvironment in 72 pre-treatment FFPE tumor sections from patients enrolled on PrECOG 0105. SPARTA was used to test and analyze the coordinated expression of PD-L1, PD-1, CD45RO, CD4, CD8 and HLA-DRA in the study cohort from whole slide scanned images. Pathologic response at the time of surgery was evaluated using the residual cancer burden index. Germline BRCA1 and BRCA2 status was known for all patients.

Results: Of 72 samples, 67 were evaluable for SPARTA analysis. Within a subset of tumors separately profiled by both SPARTA (FFPE/IHC microscopy) and CIBERSORT (Frozen/RNA GEP), we found significant correlation for clinically relevant TIL subpopulations, including for CD8+ T cells (r=0.83, p<0.0001), and activated memory CD4+ T cells (r=0.78, p<0.0001). On average, the SPARTA frequency of CD8, PD-L1, PD-1, CD45RO, CD4, CD8 and HLA-DRA in the study cohort from whole slide scanned images. Pathologic response at the time of surgery was evaluated using the residual cancer burden index. Germline BRCA1 and BRCA2 status was known for all patients.

Conclusions: Spatial mapping of the immune microenvironment in primary TNBC reveals distinct immune cell populations associated with response to neoadjuvant platinum-based therapy.
Trends in the cost of care for breast cancer among women with commercial insurance

Kathryn J Ruddy, Lindsey R Sangaralingham, Rachel A Freedman, Ahmedin Jemal, Sarah S Mougalian, Theresa Keegan, Charles L Loprinzi, Cary P Gross, Henry J Henk, and Nilay Shah. 1Mayo Clinic, Rochester, MN; 2Dana-Farber Cancer Institute, Boston, MA; 3American Cancer Society, Atlanta, GA; 4Yale University School of Medicine, New Haven, CT; 5UC Davis Health, Sacramento, CA; 6Yale Cancer Center and Yale School of Medicine, New Haven, CT and 7Optum Labs, Eden Prairie, MN.

Background: Breast cancer care imposes a significant financial burden to U.S. healthcare systems and has become a key focus in the health care debate. Therapies for breast cancer are expensive, and the economic burden of these therapies may be rising due to the rapid introduction of pricey new drugs and techniques. There are limited data on the health care costs of individuals with breast cancer after initial diagnosis and how these costs have changed over time.

Methods: We conducted a retrospective analysis of commercially insured adult women with newly diagnosed non-metastatic breast cancer (identified via previously published claims-based algorithms) using 2007-2016 data from a large US health plan available in OptumLabs® Data Warehouse. We included patients with continuous health plan coverage for at least 2 years after initial diagnosis 2007-2014 and assessed how total health care spending and out-of-pocket costs (paid amounts) changed over this time. Costs were adjusted to 2016 US dollars using the general Consumer Price Index. Inpatient, outpatient, and outpatient pharmacy costs were evaluated. A multivariable logistic regression model was used to examine predictors of above average cost (cost > mean for that year of diagnosis).

Results: A total of 12,446 newly diagnosed breast cancer patients were identified (mean age, 51.6 years). Forty percent had undergone mastectomy, 38% chemotherapy, and 63% radiation. After adjustment for inflation, total healthcare costs increased 29.7% from 2007 to 2014 (Table 1), with increases primarily observed during the first year after diagnosis. Out-of-pocket costs remained relatively stable, and accounted for 5.3% of the total spending. Approximately 80% of the total costs were related to care received in the outpatient setting. Factors independently associated with above average spending included treatment with mastectomy [OR 1.78 (95% CI 1.5-2.1)], reconstruction [OR 3.0 (95% CI 2.6-3.5)], radiation [OR 4.0 (95% CI 3.4-4.7)] and chemotherapy [OR 18.4 (95% CI 16.6-20.3)].

Conclusions: Breast cancer care is increasingly expensive during the first year after diagnosis, and costs are greatest for the recipients of more aggressive treatments. Costs during the second year after diagnosis have remained relatively stable.
Medicare costs for women after breast cancer: Preparing for survivorship

Rachel A Greenup¹, Arseniy Yashkin¹, Galina Gorbunova¹, Igor Akusevich¹ and E Shelley Hwang¹. ¹Duke University, Durham, NC.

BACKGROUND
Improvements in breast cancer survival and increasing population life expectancy have resulted in a growing number of women receiving subsequent health care after breast cancer diagnosis and treatment. We sought to determine the magnitude of increases in healthcare costs related to breast cancer survivorship, in anticipation of predicted increases in enrollment, higher intensity utilization, and greater healthcare spending among Medicare beneficiaries.

METHODS
Women age 65+ diagnosed with stage 0-III breast cancer in 1998, 2003 or 2008, were identified from the SEER database linked to Medicare records. After restrictions they were propensity score matched to a comparable group of non-breast-cancer women on demographic characteristics and co-morbidities at time of diagnosis based on the Elixhauser co-morbidity index. Line payments to care providers were then calculated for the first year of care after diagnosis (cases only) as well as years 2-6, 8-11 and 12-16 post-diagnosis (cases and controls). Direct Medicare costs were adjusted for inflation using the experimental Medicare costs Price Index and compared under real world and alternative survival scenarios.

RESULTS
Overall, the costs of care were progressively higher in later cohorts across all time periods. Differences in survivorship were the primary driver of differences in costs between breast cancer cases and controls. All-stage costs in years 2-6 were higher in the cancer group ($2,499, $10,261 and $12,029 higher per-person in 1998, 2003 and 2008 respectively), however, higher mortality in the cancer group reduced the costs and quantity of care received in later years [years 7-11 ($2,183 lower per-person in 1998) and 12-16 ($2,431 lower per-person in 1998)]. In pairs with identical survival, costs in the cancer group were significantly higher than in matched non-breast-cancer controls across all time periods (years 2-6: $4,799, $9,545 and $12,245 higher in 1998/2003/2008; years 7-11: $2,922 and $5,597 higher in 1998/2003). Stratification by stage changed the magnitude but not the general pattern of our results. The first year of care in 2003 was on average $4,933 dollars higher than in 1998; in 2008 costs again increased by $4,223 per-person. In years 2-6 the cost of cancer care increased by $12,440 (2003 vs 1998) and $3,456 (2008 vs 2003) per-person; Finally, cancer care for years 7-11 in 2003 $3,964 higher than in 1998 per-person.

CONCLUSION
Improved breast cancer survival and increased overall life expectancy among women in the United States will contribute to higher Medicare expenditures. Future risk-based capitation schemes should account for these advancements when preparing for healthcare delivery after cancer.
Purpose: We aimed to investigate the cost-effectiveness of mastectomy with and without different reconstruction for the purpose of determining which strategies represent value for money and identify the most cost-effective technique from the perspective of Ontario’s health care system.

Methods: We developed a decision analytic model to project the lifetime clinical and economic consequences of different strategies. The decision model was parameterized using 10-year follow up and cost data from Ontario administrative health databases and Ontario Cancer registry and utility data from secondary Canadian sources. Costs are presented in 2018 Canadian dollars. Future costs and benefits were discounted at 5%.

Results: Compared to organized screening-based strategy, surgical strategies ranged from being more effective and cost-saving and up to being associated with an incremental cost effectiveness ratio (ICER) of $63,010 per quality-adjusted life year (QALY) gained.

ADM; acellular dermal matrix; TE = Tissue Expander; ICER = Incremental cost-effectiveness ratio; QALY = Quality adjusted life year

, with BPM with immediate one-stage acellular dermal matrix (ADM)-assisted implant breast reconstruction having the greatest incremental QALY of 1.157 and lowest ICER of $9,615. Incorporating the PBM with one-stage ADM-assisted implant immediate breast reconstruction as the standard surgical strategy in Ontario would result in the largest total annual net gains of 20 QALYs and $1.7 million.

Conclusion: The choice of breast reconstruction needs to be decided based on the patient body habitus, general condition and...
goals. BPM with and without reconstruction is likely both clinically and economically attractive. However, all other things being equal, BPM with immediate one-stage ADM-assisted implant breast reconstruction is the most cost effective strategy and appears to offer the highest value for money.
Association between adherence to cardiovascular medications and cardiovascular events following a diagnosis of early stage breast cancer

Dawn L Hershman¹, Melissa Accordino¹, Sherry Shen¹, Donna Buono¹, Katherine D Crew¹, Kevin Kalinsky¹, Meghna S Trivedi¹, Joseph M Unger² and Jason D Wright¹. ¹Columbia University Medical Center, New York, NY and ²Fred Hutchinson Cancer Research Center, Seattle, WA.

Background: Studies show that patients diagnosed with early-stage breast cancer (BC) are more likely to die from cardiovascular disease (CVD) than BC. Adherence to CVD medications, such as statins and antihypertensives, is poor in BC survivors, particularly in the year following diagnosis. The impact of non-adherence to CVD medications on cardiovascular events in BC survivors is unknown.

Methods: Using the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked dataset, we evaluated patients with non-metastatic BC who were diagnosed between 2006-2014. Prescriptions were identified for the treatment of hypertension, hyperlipidemia and diabetes. The pre-cancer diagnosis study period for adherence was defined as 1 year prior to the diagnosis of cancer. The follow up adherence period was between years 1 and 2 following the diagnosis of cancer, so the BC treatment period was not included. Adherence was defined as a medication possession ratio of ≥80%. A CVD event was defined as an ischemic event or acute heart failure. Patients with a CVD event prior to diagnosis were excluded. Logistic regression was performed for each non-cancer condition to define factors associated with medication non-adherence. Cox regression was used to calculate the association between CVD medication adherence and time-to-subsequent cardiac events, adjusted for baseline factors. Cox regression was performed separately for each non-cancer condition.

Results: Among 23,080 women with BC in the cohort, 15,576 were adherent to at least one CVD medication prior to diagnosis, and of these, 2732 (17.5%) were non-adherent to at least one medication following treatment. Among the women adherent to medications prior to diagnosis, 19.2% were non-adherent to hypertension medications, 26.2% were non-adherent to cholesterol medications, and 30.6% were non-adherent to diabetes medications following the first year of BC treatment. Factors that were associated with non-adherence to anti-hypertensives included receipt of chemotherapy (OR 1.24, p<0.001), other comorbidities (OR 1.34, p<0.001), higher stage (OR 1.18, p<0.001) and hormone receptor negative tumors (OR 1.15, p<0.001). Similar factors were associated with non-adherence to cholesterol medications, whereas only stage and tumor type were associated with non-adherence to diabetes medications. Non-adherence to hypertension medications compared to adherence following diagnosis was associated with an increased risk of having a CVD event (HR 1.33, 95% CI 1.18-1.51, p<0.001; 5-year cumulative incidence of 32% vs 26%, respectively, p<0.001). Similar results were seen for adherence to cholesterol medications (HR 1.21, 95% CI 1.05-1.40, p=0.009) and diabetes medications (HR 1.31, 95% CI 1.09-1.56, p=0.003).

Conclusions: In summary, we found that a large proportion of women who were previously adherent to their medications to prevent CVD events prior to their breast cancer diagnosis were non-adherent following treatment. Of concern, non-adherence to any of these classes of medications resulted in an increased risk of having a cardiovascular event. Improving outcomes and reducing morbidity following a breast cancer diagnosis also requires focused attention on non-breast cancer conditions.
Evaluating racial disparities in breast cancer referrals for hereditary risk assessment

Abigail Pepin\textsuperscript{1}, Jennifer Peterson\textsuperscript{2}, Rehema Thomas\textsuperscript{1}, Kerry Johnson\textsuperscript{3}, Elizabeth Stark\textsuperscript{3}, Tara Biagi\textsuperscript{3} and Rebecca Kaltman\textsuperscript{3}. \textsuperscript{1}GW Medical School, Washington, DC; \textsuperscript{2}Des Moines University Medical School, Des Moines, IA and \textsuperscript{3}GW Medical Faculty Associates, Washington, DC.

**Background**: There is a pronounced onco-racial disparity in Washington, D.C., which had the highest national incidence of breast cancer in African Americans (AA) patients in between 2010-2015 and the worst outcomes (American Cancer Society). Recent data indicates a higher incidence of deleterious BRCA1 [and BRCA2] mutations and variants of uncertain significance (VUS) in AA patients compared to Caucasian (C) patients when controlled for patients of Ashkenazi Jewish (AJ) populations (Hall 2009). Despite this, AA women meeting National Comprehensive Cancer Network (NCCN) criteria for genetic testing are less likely to complete such testing compared to C women nationally. Studies have investigated psycho-social drivers of minority patient aversion to genetic testing. We hypothesize that lack of physician referral for cancer genetic counseling and testing for AA women contributes to this disparity.

**Methods**: The George Washington Cancer Center (GWCC) Registry was used to identify non-Hispanic African Americans (BNH) and non-Hispanic whites (WNH) treated for breast cancer between 2014-2018. Of those individuals selected for inclusion were those who met select NCCN criteria for referral for genetic evaluation including breast cancer diagnosis under age 50, triple negative breast cancer (TNBC) under age 60, and two primary breast cancers. Only BNH and WNH individuals were included. Excluded patients were those who were not BNH or WNH or who did not meet the NCCN criteria listed above. Patients were then stratified by race according to who underwent genetic evaluation, whether at our Ruth Paul Cancer Genetics and Prevention Service (RPCGPS) or elsewhere, by reviewing GWCC, RPCGPS, and patient clinic records for genetic testing results from outside institutions. Patient charts were used to identify individuals who received a physician referral over the course of their cancer care.

**Results**: 1180 patients were treated at the GWCC for breast cancer (both in situ and invasive carcinoma) between 2014–2018. Of those, BNH n=502; WNH n=435. Twenty-seven percent of BNH and WNH patients met the study criteria for referral for genetic evaluation (n=252; BNH n=115, WNH n=137), including breast cancer diagnosis under age 50 (BNH n=76; WNH n=108), TNBC under age 60 (BNH n=14; WNH n=5), and two primary breast cancers (BNH n=18, WNH n=16). Several patients identified met two or more criteria for referral (BNH n=7, WNH n=8). Physician referral rates differed significantly by race (BNH 76%, n=87 and WNH 91%; n=125; χ²=11.4, p-value<0.001). Of referred patients, there was no significant difference in those who followed-up at RPCGPS by race (BNH 93%, n=81; WNH= 93%, n=116, χ² =0.0072, p-value=0.93).

**Conclusions**: Low genetic testing rates for AA breast cancer patients are an impediment to resolving the prominent onco-racial breast cancer disparities. This study identified physician referral as a potential contributor to racial disparity in the utilization of cancer genetics services. Potential reasons for the discrepancy in referral may include lag in physician education on the topic of hereditary risk and barriers in physician-patient communication. These findings need to be confirmed and explored at other sites to help improve the identification of at-risk women in the AA community.
Prevalence and predictors of self-reported memory ability in a large sample of breast cancer survivors

Lori J Bernstein\textsuperscript{1,2}, Danielle N D’Amico\textsuperscript{1,3}, Nadine M Richard\textsuperscript{1}, David R McCready\textsuperscript{1,2}, Doris Howell\textsuperscript{1,2}, Jennifer M Jones\textsuperscript{1,2} and Kim Edelstein\textsuperscript{1,2}. 1Princess Margaret Cancer Centre, University Health Network, Toronto, Canada; 2University of Toronto, Toronto, Canada and 3Ryerson University, Toronto, Canada.

Background: A substantial subset of women previously treated for breast cancer report deficits in cognitive abilities such as memory. Cancer-related cognitive dysfunction (CRCD) has been linked to a variety of factors including chemotherapy. However, the reported prevalence of symptoms is variable and investigations of CRCD correlates in large samples are limited. This study aimed to 1) investigate whether the prevalence of patient-reported memory problems differs as a function of having received chemotherapy and time-since-treatment; and 2) identify additional factors associated with patient-reported memory in a large sample of breast cancer survivors.

Method: In this cross-sectional cohort study, self-administered questionnaires including those assessing memory (Multifactorial Memory Questionnaire) and lifestyle behaviors were mailed to 1500 disease-free breast cancer survivors from three time-since-treatment cohorts (early: 6-18 months, middle: 2-4 years, or late: 5-12 years post-treatment). Demographic and clinical information was collected and confirmed from chart review. The prevalence of clinically significant memory dysfunction was estimated using published normative cut-off scores. We tested whether chemotherapy and time-since-treatment affected memory (analysis of variance), or increased the risk of significant memory dysfunction (odds ratio chi-squared test). Using a forward stepwise regression model, we explored whether patient characteristics (age, education, comorbidities, concussion history, adverse life events), type of treatment (chemotherapy, radiotherapy, hormonal therapy), or lifestyle behaviors (adherence to a Mediterranean diet, physical activity, sleep efficiency, stress management practices) were associated with patient-reported memory.

Results: 773 questionnaire packages were returned (mean age=60.4±11.7). 436 (56\%) survivors had received chemotherapy (Ch\textsuperscript{+}), and 337 (44\%) had not (Ch\textsuperscript{-}). 314 (41\%) were early survivors, 244 (32\%) were middle, and 215 (28\%) were late. Ch\textsuperscript{+} reported poorer memory than Ch\textsuperscript{-} (\(F(1, 764)=12.752, p<0.001\)), with no effect of time-since-treatment or interaction. Prevalence of significant memory dysfunction was higher in Ch\textsuperscript{+} (28\%) than in Ch\textsuperscript{-} (15\%) (OR=2.130, 95\% CI 1.479-3.066). Younger age and history of concussion were significantly associated with worse patient-reported memory (\(p=0.002, p<0.001\)). Unlike chemotherapy (\(p=0.018\)), neither radiation nor hormonal treatment was a significant predictor of memory symptoms. Increased physical activity (\(p=0.002\)) and higher sleep efficiency (\(p<0.001\)) were associated with better memory. Survivors reporting greater memory symptoms also reported greater use of stress management techniques (\(p=0.026\)).

Conclusion: This large study indicates that chemotherapy doubles the risk of memory symptoms up to at least 10 years post-treatment. Results also point to sleep hygiene and physical activity as potentially meaningful targets for self-management training to reduce CRCD in breast cancer survivors.
A randomized, controlled trial of high dose vs. standard dose vitamin D for aromatase inhibitor-induced arthralgia in breast cancer survivors

Polly Niravath¹, Tao Wang¹, Susan G Hilsenbeck¹, Katy Lipscomb¹, Anne Pavlick¹, Sao Jiralerspong¹, Julie Nangia¹, Matthew Ellis¹, Foluso Ademuyiwa², Mathew Cherian², Ashley Frith², Cynthia Ma², Haeseong Park², Caron Rigden², Rama Suresh², C Kent Osborne¹ and Mothaffar F Rimawi¹. ¹Baylor College of Medicine, Houston, TX and ²Washington University School of Medicine, St. Louis, MO.

Background: Approximately half of women on aromatase inhibitor (AI) therapy develop AI-induced arthralgia (AIA), and many discontinue the medication because of this common side effect. While Vitamin D has been studied as a treatment for AIA, trial results have been conflicting thus far.

Patients and Methods: All subjects were post menopausal women who were beginning adjuvant AI therapy for stage I-III hormone receptor positive breast cancer. Patients were randomized 1:1 to receive standard dose vitamin D³ (800 IU daily for 52 weeks) or high dose vitamin D³ (50,000 IU weekly for 12 weeks, followed by 2000 IU daily for 40 weeks). All patients also took oral calcium 600 mg daily. The primary endpoint was development of AIA, as defined by pre-specified changes in the Health Assessment Questionnaire II (HAQ-II). Secondary endpoints include compliance with AI therapy, and correlation between grip strength and development of AIA. Exploratory endpoint was measurement of inflammatory cytokine reduction in each arm. The trial was designed to enroll 184 patients, but this futility analysis was performed after 93 patients were enrolled. The futility boundary for stopping the trial early was calculated as p = 0.47.

Results: All 93 patients (46 in the high dose arm, and 47 in the standard dose arm) enrolled in the study at the time of the interim analysis were evaluable. The HAQ-II was completed at 12 weeks in 76% on the high dose arm, and 68% in the standard dose arm. Subjects who did not complete the questionnaire were deemed as study failures (i.e. development of AIA was assumed). In the high dose arm, 25 patients (54%) developed AIA, compared to 27 patients (57%) in the standard dose arm. The one-tailed p value is 0.3818, and the Z-score is 0.3, yielding only a 38% conditional power that that study would find a significant difference between the two arms. Thus, the study was terminated early for futility. There was no significant difference between the two arms in adherence to AI therapy. The grip strength and inflammatory cytokine data are pending at this time. They will be ready by the time of the conference.

Conclusions: There was no significant signal for benefit of high dose vitamin D supplementation, as compared to standard dose vitamin D, for AIA prevention in post menopausal women taking adjuvant AI therapy. These results further characterize the role of Vitamin D in AIA, and they inform future clinical trials in this arena. Further research is necessary, as this remains an important cause of non-adherence to this highly effective therapy.
Lifestyle intervention study (LISA) in early breast cancer (BC): An RCT of the effects of a telephone-based weight loss intervention (with educational materials) vs educational materials alone on disease-free survival (DFS)

Pamela J Goodwin,1,2,12 Roanne Segal,3 Jennifer A Ligibel,5 Greg R Pond,6,8 André Robidoux,7 Brian P Findlay,6,8 Julie R Gralow,6,10 Mark N Levine,6,10 and Kathleen I Pritchard1,11,12. 1Mount Sinai Hospital, Toronto, Canada; 2Lunenfeld-Tanenbaum Research Institute, Toronto, Canada; 3Ottawa Regional Cancer Centre, University of Ottawa, Ottawa, Canada; 4Dalhousie University, Halifax, Canada; 5Dana-Farber Cancer Institute, Boston; 6McMaster University, Hamilton, Canada; 7Centre Hospitalier de l’Université de Montréal, Montreal, Canada; 8Niagara Health System, St. Catherines, Canada; 9Fred Hutchinson Cancer Research Center, University of Washington, Seattle; 10Juravinski Cancer Center, Hamilton, Canada; 11Sunnybrook Research Institute, Toronto, Canada and 12University of Toronto, Toronto, Canada.

Background: Obesity has been associated with poor BC outcomes. We investigated whether a standardized, telephone-based weight loss lifestyle intervention in recently diagnosed BC patients would lower recurrence and death rates.

Methods: We conducted a multicenter RCT comparing mail-based educational material alone (control arm) or combined with a standardized, telephone-based lifestyle intervention (19 calls over 2 years, (intervention arm) that focused on diet (500-100 kcal/day deficit), physical activity (150-200 minutes of moderate-intensity activity per week) and behavior (compliance, relapse prevention) to achieve up to 10% weight loss. 338 (of 2150 planned) T1-3, N0-3, M0 ER/PgR+ BC patients with body mass index (BMI) ≥ 24 kg/m² receiving adjuvant letrozole were randomized Aug 2007 to Jan 2010 (enrolment ended due to funding loss). Primary outcome was DFS; secondary outcome OS. Weight loss (5.3 vs 0.7% at 6 months and 3.6 vs 0.4% at 24 months in the intervention vs control arms, respectively) has been reported (JCO 2014;32:2331). At 8 years median follow-up (May 2018), DFS and OS were compared using Cox proportional hazards regression.

Results: Mean age was 61.6 vs 60.4 years, mean BMI 31.4 vs 31.0 kg/m² and adjuvant chemotherapy was received by 56.1 vs 57.5% in intervention vs controls arms respectively. T1/T2/T3 66.7/27.5/5.9% vs 61.7/33.5/3.6% and N0/1/2+ 62.6/28.7/8.8 vs 63.5/32.3/4.2% in intervention vs controls arms respectively. HER2+ in 8.8 vs 15.0% (intervention vs control). 20 of 171 (11.7%) in the lifestyle intervention arm vs 30 of 167 (18.0%) in the mail-based arm had DFS events, HR 0.71, 95%CI 0.41-1.24, p=0.23). DFS curves separated at 2 yrs; beyond 3-3.5 yrs separation approximated 5%. In a landmark DFS analysis of women alive at 24 months, DFS HR=0.68 (0.34-1.37, p=0.28).

Conclusions: We identified fewer DFS events in the lifestyle intervention arm. Although loss of funding reduced sample size and lowered power, these results are consistent with a potential beneficial effect of a lifestyle intervention on DFS in postmenopausal ER/PgR+ BC patients. They provide strong support for completion of ongoing RCTs (e.g. BWEL) that will provide definitive evidence regarding the effect of lifestyle based weight loss on BC outcomes.

Recreational physical activity and breast cancer risk for women across the familial risk continuum

Rebecca D Kehm, Kelly-Anne Phillips, Mary B Daly, Irene L Andrulis, Yuyan Liao, Xinran Ma, Nur Zeinomar, Robert J MacInnis, Gillian S Dite, Esther M John, Saundra S Buys, Roger L Milne, John L Hopper and Mary Beth Terry.

Columbia University Mailman School of Public Health, New York, NY; Sir Peter MacCallum Department of Oncology, the University of Melbourne, Melbourne, Australia; School of Population and Global Health, The University of Melbourne, Melbourne, Australia; Peter MacCallum Cancer Centre, Melbourne, Australia; Fox Chase Cancer Center, Philadelphia, PA; Lunenfeld-Tanenbaum Research Institute, University of Toronto, Toronto, ON, Canada; Cancer Prevention Institute of California, Fremont, CA; Stanford University School of Medicine, Stanford, CA; Huntsman Cancer Institute, University of Utah School of Medicine, Salt Lake City, UT and Herbert Irving Comprehensive Cancer Center, Columbia University Medical Center, New York, NY.

Significance: Physical activity is associated with a 20-30% reduced breast cancer risk for women unselected for risk, yet it is not known if this benefit extends to women spanning the range of familial risk. We addressed this gap by examining the association of recreational physical activity and breast cancer risk using a large cohort of women over-sampled for having breast cancer family history.

Methods: We studied 15,622 women, including 1,171 BRCA1 and BRCA2 gene mutation carriers, who were unaffected with breast cancer at baseline and followed prospectively for cancer (median follow-up = 10.2 years). At baseline, women self-reported average hours per week of recreational moderate and strenuous physical activity during the past 3 years. We categorized women into quintiles based on total metabolic equivalents (METs) per week (1 hour moderate = 4 METs; 1 hour strenuous = 7 METs) and examined associations with risk of invasive breast cancer, overall and stratified by baseline age, using multivariable Cox proportional hazards regression. We tested for multiplicative and additive interaction by familial risk, defined as the estimated absolute lifetime breast cancer risk predicted using the Breast Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA) model.

Results: Combining women of all ages, doing any recreational physical activity (versus none) was associated with a decreased breast cancer risk (hazard ratio (HR) = 0.75, 95% confidence interval (CI) = 0.63-0.90), but there was no decrease in risk with increasing METs per week (p-trend = 0.27). Only for women 50-59 years at baseline was there evidence for a dose-response trend with increasing physical activity (p-trend = 0.04). The most physically active women, quintile 5 (Q5), had an estimated 39% reduced breast cancer risk compared to the least physically active women, quintile 1 (Q1), in this age group (HR = 0.61, 95% CI = 0.40-0.93). We found no evidence of interaction with familial risk, overall or stratified by baseline age (all p > 0.05).

Conclusion: Performing recreational physical activity appears to be associated with a reduced breast cancer risk for women spanning the familial risk spectrum.

Impact of \textit{BRCA} mutations on chemotherapy-induced loss of ovarian reserve: A prospective longitudinal study

Kutluk Oktay\textsuperscript{1}, Giuliano Bedoschi\textsuperscript{1}, Shari B Goldfarb\textsuperscript{2}, Enes Taylan\textsuperscript{1}, Shiny Titus\textsuperscript{1}, Glenn E Palomaki\textsuperscript{3}, Tessa Cigler\textsuperscript{4}, Marc Robson\textsuperscript{2} and Maura N Dickler\textsuperscript{2}. \textsuperscript{1}Yale University School of Medicine, New Haven; \textsuperscript{2}Memorial Sloan Kettering Cancer Center, New York; \textsuperscript{3}Women & Infants Hospital and Alpert Medical School at Brown University, Providence and \textsuperscript{4}Weill Medical College of Cornell University, New York.

\textbf{Background:} The \textit{BRCA}1/2 genes are key members of the ataxia-telangiectasia mutated (ATM)-mediated DNA double strand break (DSB) repair pathway. Recent research showed that germline mutations in these genes result in DNA repair deficiency in oocytes, leading to accelerated ovarian aging as manifested by lower ovarian reserve and earlier age at natural menopause. Because we discovered that oocyte DNA repair is similarly critical in chemotherapy-induced ovarian follicle loss, we hypothesized that women with pathogenic mutations in \textit{BRCA}1/2 genes may experience larger declines in ovarian reserve after chemotherapy. To gauge the degree of the chemotherapy-induced ovarian damage, we utilized serum anti-mullerian hormone (AMH), which is the most reliable current marker for assessing oocyte reserve.

\textbf{Methods:} Women with early stage breast cancer were enrolled before chemotherapy (Trial registration number: NCT00823654) between January 2009 and November 2017. Sera were obtained at baseline, before the initiation of treatment, and 18 to 24 months after the completion of chemotherapy. Stored sera were assayed at once for anti-mullerian hormone (AMH) and the results were adjusted for the women's age at sample collection. Of the 235 enrolled, 117 evaluable women were stratified into three groups, those never tested (based on NCCN Guidelines V 1.2018 ; n=38) and those negative (n=65) or positive (n=14) for a pathogenic \textit{BRCA} mutation. Ovarian recovery was defined as the geometric mean of the post chemotherapy age-adjusted AMH levels compared to baseline.

\textbf{Results:} Compared to the lower risk (BRCA-untested) control group, AMH levels averaged 76\% and 66\% in those negative or positive for \textit{BRCA} mutations (p=0.078). The geometric mean recoveries for the three groups (not tested, \textit{BRCA} negative and \textit{BRCA} positive) were 3.7\%, 5.2\% and 1.6\%, respectively. The mean recovery in the \textit{BRCA} mutation positive group was about one-third the 4.6\% recovery in the other two groups combined (two group ANOVA, p=0.034, F=4.89). Given the potential of the ovarian recovery to be dependent on type of chemotherapy, the data were reanalyzed for all three \textit{BRCA} groups after restriction to those treated with the AC-T (doxorubicin and cyclophosphamide followed by paclitaxel) regimen. Of the 108 women in the previous analysis, 83 (77\%) were treated with AC-T; 25, 46 and 12 women in the three groups, respectively. The geometric mean AMH recoveries for these new groups were 3.2\%, 4.7\% and 1.3\%. When the \textit{BRCA} mutation positive group was compared with other two groups, the former had significantly worse recovery of serum AMH levels (ANOVA, p=0.044, F=4.2).

\textbf{Conclusions:} These data show that women with breast cancer and pathogenic \textit{BRCA} mutations have striking liability to chemotherapy-induced ovarian reserve loss and may have to be preferentially counselled on fertility preservation methods. In addition, taken together with the previous data showing that women with \textit{BRCA} mutations may have accelerated ovarian aging, even unaffected reproductive age individuals may have to be proactive about family building or early preservation of their fertility (Supported by NIH R01HD053112).
Pilot project assessing the impact of self-care techniques on post-surgical pain, fatigue, and inflammation

Robert F Setlik1, Alice Inman1, Kimberly Peacock2, James Aden1, Charmagne Paat3, Erika Stoerkel3, Dawn Bellanti3 and Joan Walter4. 1Brooke Army Medical Center, Fort Sam Hourston, TX; 2University of Texas Health, San Antonio, TX; 3Thought Leadership and Innovation Foundation, McLean, VA and 4Samueli Institute, Silver Spring, MD.

More than one third of women diagnosed with breast cancer experience significant emotional distress, which may then effect pain perception, wound healing, quality of life (QOL), and return to physical function. Several studies have shown that physical and cognitive relaxation strategies may relieve perioperative anxiety, leading to improved postoperative pain and QOL. One hundred women from Brooke Army Medical Center with non-metastatic breast cancer, planning to undergo surgery as initial treatment, were randomly assigned using an intention-to-treat model to either the treatment as usual group (TAU; n = 49) or TAU plus a self-care toolkit (SCT; n=51). The SCT included audio-recordings of guided mind-body techniques (breathing, progressive muscle relaxation, meditation, guided imagery, and self-hypnosis), an acupressure anti-nausea wristband, and a workbook with instructions for use of the tools plus a section to journal the cancer experience.

Pain, anxiety, nausea, sleep, fatigue, global health, and QOL were assessed using the Defense and Veterans Pain Rating Scale (DVPRS), the 10-cm Visual Analog Scale (VAS), and the NIH PROMIS-57 subscales. Data was collected at baseline (T1), immediately prior to surgery (T2), within 10 hours post-operatively (T3), and approximately two weeks post-surgery (T4). Two inflammatory blood markers (ESR and CRP) were measured at T1, T2, and T4. Due to diurnal variability of ESR and CRP, laboratory draws were generally collected prior to 10:00 AM. Categorical variables and frequency counts were analyzed using Chi-Squared or Fisher's Exact tests, whichever was most appropriate. Means and standard deviations were used as summary statistics for continuous variables and analyzed using Student's t-test, ANOVA, and/or Wilcoxon's Test. For data measured at two time points, the delta change in values was calculated to detect within-group differences in SCT and TAU using Wilcoxon's rank sum test or paired t-test. For factors measured at more than two time points, a two-way repeated measures ANOVA was implemented with a Bonferroni corrected post-hoc analysis to determine between-group differences at each time point.

Between T1 and T4, there were significant between group differences in PROMIS-57 scores of Pain Interference, Fatigue, and Satisfaction With Social Roles, favoring the SCT group compared to TAU (p=0.005, p=0.023, and p=0.021, respectively). There was a significant mean change in DVPRS scores from T2 to T3, with the SCT group having significantly smaller increases in post-operative pain (p=0.008) and in post-operative ESR (p=0.0197) compared with the TAU group. Clinically significant reductions in anxiety occurred in the SCT group during the main intervention period. These results suggest that using the SCT in the perioperative period decreased pain perceptions, fatigue, and inflammatory cytokine secretion.

Invasive lobular carcinoma (ILC) is a subtype of breast cancer comprising 10% of breast tumours. ILC is characterised by a loss of E-cadherin, and is generally estrogen receptor (ER) positive. The majority of ILC breast cancers are treated with endocrine therapy, although approximately one in three women are de novo resistant to therapy. To identify novel therapeutic targets for the treatment of ILC, we carried out RNA sequencing on 61 primary ILC samples. We found that high expression of the epigenetic reader, bromodomain protein 3 (BRD3) was associated with poor recurrence free survival. We also validated this finding in a separate cohort of 99 ILC patient samples using the METABRIC cohort. Next, we assessed ILC cell lines for sensitivity to JQ1, an inhibitor of BET family proteins. We found that JQ1 inhibited cell growth in all the cell lines tested. Interestingly, two of the ILC cell lines were sensitive to JQ1-induced apoptosis, whereas two of the cell lines were inherently resistant to JQ1-induced apoptosis. Using dynamic BH3 profiling we showed that the JQ1 resistant cell lines were dependent on anti-apoptotic protein BCL-XL following JQ1 treatment. Interestingly, we show both in 2D and 3D cultures that JQ1 is synergistic when combined with the BH3 mimetic, ABT-263. Highlighting that combination treatment with JQ1 and ABT-263 may be a novel potential therapeutic option for ILC.

To unveil the mechanism underlying resistance to JQ1-induced apoptosis, we performed paired-end RNA sequencing and compared differentially expressed genes in JQ1 sensitive and JQ1 resistant ILC cell lines. DAVID gene ontology analysis identified 6 pathways differentially upregulated in the JQ1 resistant ILC cell line including MAPK, Wnt, and insulin resistance signaling. Interestingly, we found that ILC cell lines, which were resistant to BET inhibition with JQ1, demonstrated high levels of FGFR1-4 both at the mRNA level and the protein level. Combination treatment with JQ1 and the FGFR inhibitor PD173074 or following knockdown of FGFR with siRNA, resulted in increased cell death in JQ1 resistant cells. Currently, we are assessing how FGFR signaling enables survival of ILC cells following JQ1 treatment and determining the exact function of BRD3 in ILC. In conclusion, we have identified a novel therapeutic target, BRD3, which may be inhibited using JQ1 in combination with BH3 mimetic ABT-263 or FGFR1 inhibitor for a more effective treatment strategy for ILC.
Novel human cell line xenograft models of ERα-positive metastatic invasive lobular breast carcinoma as pre-clinical platforms for validating candidate genetic drivers

Nilgun Tasdemir¹, Julie Scott¹, Joseph Laotche¹, Weizhou Hou¹, Emily A Bossart¹, Jennifer Atkinson¹, George Sflomos², Sreeja Sreekumar³, Carlos Castro¹, Carolyn Anderson¹, Adrian V Lee¹, Cathrin Brisken², Peter C Lucas¹, Nancy E Davidson³ and Steffi Oesterreich¹. ¹University of Pittsburgh, Pittsburgh, PA; ²École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland and ³Fred Hutchinson Cancer Research Center, Seattle, WA.

Invasive lobular breast carcinoma (ILC) is the second most common subtype of breast cancer following invasive ductal breast carcinoma, accounting for 10-15% of all cases. Despite the intriguing histological and clinical differences between these two subtypes, ILC has been chronically understudied. Human ILC cell lines and xenografts are regarded to be of limited utility for ILC research due to slow proliferation rates in culture and low reported intake rates. Data on human ILC cell line xenografts remains limited and knowledge of their metastatic capacity is currently lacking. Using Estrogen Receptor alpha (ER)-positive human ILC cell lines labeled with dual bioluminescent and fluorescent reporters, herein we performed a comprehensive in vivo characterization of their growth as primary tumors orthotopically in the mammary fat pad, as well as at secondary sites following spontaneous or experimental metastasis. Primary tumors exhibited the characteristic dyscohesive, single-file growth of ILC cells, faithfully recapitulating the histology of human ILC tumors. In vivo bioluminescence imaging coupled with ex vivo fluorescence analysis revealed spontaneous metastases to the bone, brain, lungs and ovaries, closely mirroring the clinical patterns of ILC tumor dissemination. This was in stark contrast to experimental metastasis, where none of the cell lines colonized the lungs when injected into the tail vein and bone colonization was observed with only one cell line following intracardiac injections. The metastatic lesions harbored the classical histological features of ILC, including single strand growth, loss of E-cadherin-mediated adherens junctions and mislocalization of p120-catenin to the cytoplasm. Importantly, both the primary tumors and the metastases exhibited high ER expression and significant response to the anti-endocrine agent fulvestrant - a selective ER downregulator. Using these models, we will also present data from functional studies validating candidate genetic drivers of ILC disease progression, which are associated with poor recurrence-free survival in patients with ILC. Ongoing work focused on genomic and transcriptional analyses of metastatic lesions and isolated cell lines from these models will pinpoint additional candidate drivers of ILC dissemination. This is the first report of a hormone responsive ER+ metastatic xenograft model faithfully representing unique ILC features such as ovarian metastases, which will serve as a valuable pre-clinical platform for testing novel therapeutics towards translation into the clinic.
Investigating cortactin as a genetic driver of disease progression in invasive lobular carcinoma

Nilgun Tasdemir¹, Matthew J Sikora¹, Li Zhu¹, Kevin M Levine¹, Julie Scott¹, Ahmed Basudan¹, George Sflomos³, Sreeja Sreekumar¹, Emily A Bossart¹, Esther Elishaev¹, Uma R Chandran¹, George C Tseng¹, Rachel C Jankowitz¹, David J Dabbs¹, Priscilla F McAuliffe¹, Cathrin Brisken³, Nancy E Davidson⁴ and Steffi Oesterreich¹. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Colorado Denver, Denver, CO; ³École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland and ⁴Fred Hutchinson Cancer Research Center, Seattle, WA.

Invasive lobular carcinoma (ILC) is the second most common type of breast cancer following invasive ductal carcinoma (IDC) and accounts for 10-15% of all cases. Unlike the masses or lumps formed by IDCs, ILCs grow as small, dyscohesive cells in a single-file pattern within dense layers of extracellular matrix. Paradoxically, while patients with ILC display favorable prognostic and predictive factors (Estrogen Receptor [ER]+, Progesterone Receptor+, HER2-, low Ki67), they present with more frequent long-term recurrences compared to those with IDC, indicative of endocrine resistance. Thus, there is urgent need to investigate genetic drivers of ILC disease progression in order to develop more effective therapeutic strategies and improve patient outcome. To this end, we used the Nanostring platform to measure the expression of 577 copy number variation-associated genes in 131 primary ILC tumors with long-term clinical data. This analysis identified CTTN (Cortactin; cortical actin binding protein) as a candidate ILC driver that exhibited higher expression in tumors from patients with subsequent recurrent (n=33) versus non-current disease (n=98). We further validated high CTTN mRNA/protein expression in human ILC cell lines, tumors and patient-derived xenografts, and CTTN locus (11q13.3) amplification in clinical ILC metastases to the brain, bone and ovaries. In follow-up in vitro studies, RNAi-mediated inhibition of CTTN diminished the adhesion and haptotaxis of human ILC cell lines to Collagen I, as well as impairing their growth in 3D Collagen I culture. To assess the functional role of CTTN in ILC tumor growth and metastasis, we transplanted control and CTTN knockdown human ILC cell lines into the mammary fat pads and ducts of immuno-compromised mice and monitored disease progression via bioluminescence imaging. While CTTN inhibition did not lead to a substantial impact on measurable tumor burden, both CTTN shRNAs resulted in a significant survival benefit in the fat pad model. Ongoing work is aimed at pinpointing the underlying mechanisms of CTTN's role in mediating growth in 3D Collagen I culture in vitro and disease progression in vivo. Collectively, the results of these studies will advance our understanding of ILC disease mechanisms and serve as a pre-clinical basis for improving the clinical outcome of patients with this understudied subtype of breast cancer.
Metabolic syndrome increases risk of recurrence and impacts immune pathways in invasive lobular carcinoma

Patricia Robinson¹, Tina Treece², Clodia Osipo¹, Sahra Uygun³, Heather Kling², Rubina Qamar⁴, Robin Zon¹, Ellis Levine⁵, Raye Budway⁶, Blanche Mavromatis⁷, Sarah Untch², Rene Bernards²,⁸, William Audeh², Hatem Soliman⁹ and IMPACt Investigators Group². Loyola University of Chicago, Stritch School of Medicine, Maywood, IL; ²Agendia, Inc, Irvine, CA; ³Aurora Health, Milwaukee, WI; ⁴Northern Indiana Cancer Research Consortium, South Bend, IN; ⁵Roswell Park Comprehensive Cancer Center, Buffalo, NY; ⁶St. Clair Hospital, Bethel Park, PA; ⁷Western Maryland Health, Cumberland, MD; ⁸The Netherlands Cancer Institute, Cancer Genomics Center, Amsterdam, Netherlands and ⁹Moffitt Cancer Center, Tampa, FL.

Background: Invasive lobular carcinoma (ILC) of the breast has been shown to be more strongly associated with risk factors that modulate hormone levels, including obesity, as compared with invasive ductal carcinoma (IDC). Our previous study indicated the biology of disease engages disparately for ILC and IDC. This study further evaluated the effect of metabolic syndrome (MS) in patients with ILC histopathological tumor types using whole transcriptome gene expression (GEA) and pathway analyses.

Methods: This analysis included 76 patients with ILC from the PROMIS and IMPACt studies for whom metabolic characteristics were captured with informed consent. To be classified as having MS, the patient had to exhibit any 3 of the 5 metabolic factors (obesity, hypertension, hypercholesterolemia, hypertriglyceridemia, diabetes mellitus). Risk of recurrence was established using the 70-gene signature (70-GS). Pathway enrichment analysis was performed in DAVID v 6.8 (https://david.ncifcrf.gov/). Benjamini-Hochberg corrected P< 0.05 was considered significant.

Results: Thirty-four percent (26/76) of patients with ILC had MS. Significantly more ILC patients with MS than without MS were 70-GS high risk (42% vs. 12%, respectively, [P=0.007]).

GEA identified 486 significant differentially expressed genes between MS and non-MS ILC patients. These differentially expressed genes indicated that the immune pathways were affected rather than growth factor pathways. The significantly enriched pathways were driven by genes upregulated on average across all MS ILC patients, and represented in the immune response (P< 0.001), adaptive immune response (P=0.001), B cell signaling (P< 0.001), inflammatory response (P<0.05), chemokine-mediated signaling (P<0.05), T cell co-stimulation (P<0.05), and intracellular signal transduction processes (P<0.05); as well as enriched in systemic lupus erythematosus (largely overlapping with nucleosome assembly, P=0.001) and osteoclast differentiation (P<0.05) pathways. While early infiltration of cytolytic T-lymphocytes may protect against tumor development, humoral-mediated immunity and a sustained state of chronic inflammation may result in polarization toward a pro-tumor microenvironment.

Conclusions: ILC is generally considered to have a low risk of recurrence, but with poorer long-term prognosis. We show that ILC patients with MS have a significantly higher 70-GS risk of recurrence than their non-metabolic counterparts. Our gene expression analysis suggests that ILC in the setting of metabolic syndrome, likely results in chronic immune activation and has distinct drivers of disease progression and metastasis, specifically to bone. The current study underscores the complex interplay between inflammation and immune suppression. Studies are needed to further characterize differences in enriched pathways as it relates to optimizing targeted therapeutics.
Correlation of $CDH1$ alterations and aberrant E-cadherin expression in lobular carcinomas

Anne Grabenstetter¹, Abhinita S Mohanty¹, Deborah F DeLair¹, Lee K Tan¹ and Dara S Ross¹. 'Memorial Sloan Kettering Cancer Center, New York.

**Background:** E-cadherin (ECAD), encoded by the $CDH1$ gene, is expressed in the majority of invasive ductal carcinomas (IDC). In contrast, ECAD expression is lost in ~90% of invasive lobular carcinomas (ILC) due to genomic alterations of $CDH1$. Immunohistochemical (IHC) staining for ECAD has thus increasingly been utilized to differentiate between ductal and lobular lesions. This study examines the correlation between $CDH1$ mutation profile, morphology and ECAD IHC status in invasive breast carcinomas (BC).

**Methods:** The Memorial Sloan Kettering-Integrated Mutation Profiling of Actionable Cancer Targets (MSK-IMPACT) platform is a hybrid capture next-generation sequencing assay to detect somatic alterations in exons and selected introns of 468 cancer-related genes. Invasive BC tested from 1/2014 – 5/2018 which yielded a $CDH1$ alteration were identified and only cases with ECAD IHC results were included. Histologic features were extracted from pathology reports. All available H&E/ECAD slides were reviewed by two pathologists to confirm the histology and immunophenotype.

**Results:** $CDH1$ alterations were identified in 455 out of 4103 BC analyzed (11%) and ECAD IHC were available for 209 (46%) tumors. Most of the tumors were reported as ILC (70%, 147/209). The majority (77%, 161/209) were ECAD-negative but 23% (48/209) showed some ECAD staining. Table 1 summarizes the histologic subtypes and IHC results. Upon review of H&E/ECAD slides in cases with ECAD staining, the histologic subtype was re-classified in 52% (25/48) of cases (Table 2). For ECAD-negative BC, at least 61% (98/161) of $CDH1$ alterations were truncating mutations (frameshift deletion 47/161, nonsense 51/161) and 39% (63/161) were variants of unknown significance (VUS). In cases with ECAD staining, 48% (23/48) of $CDH1$ alterations were truncating mutations (frameshift deletion 12/48, nonsense 11/48) however 52% (25/48) were VUS.

**Conclusion:** In this study, 88% (141/161) of cases with negative ECAD staining and $CDH1$ alteration were classified as ILC, confirming the known observation that $CDH1$ alteration and loss of ECAD expression is relatively specific for a lobular phenotype. The correlation is, however, imperfect. A subset of BC (23%; 48/209) with $CDH1$ alteration still exhibits ECAD expression. Morphologically this subset consists of ILC in 60% (29/48), IMC in 25% (12/48) and IDC in 15% (7/48). Our preliminary findings suggest that aberrant ECAD expression can occur in BC with morphologic features of ILC due to certain $CDH1$ alterations that most likely result in non-functional ECAD complex. BC with histologic features of ILC should therefore not be re-classified as IDC/IMC based solely on the status of ECAD expression. Given that ILC is clinically distinct from IDC, correct classification based on morphological and molecular features is prudent.

Molecular subtypes of invasive lobular breast cancer in the I-SPY2 TRIAL

Zelos Zhu¹, Christina Yau¹, A Jo Chien¹, Tufia Haddad², Laura J Esserman¹, Laura van't Veer¹, Rita A Mukhtar¹ and I-SPY2 Consortium³. ¹University of California San Francisco, San Francisco, CA; ²Mayo Clinic, Rochester, MN and ³Quantum Leap, San Francisco, CA.

**Background:** Invasive lobular carcinoma (ILC) of the breast has distinct histological and molecular variations compared to invasive ductal carcinoma (IDC), including absence of the adhesion protein E-cadherin. Recently, molecular subtypes within ILC have been described, with an analysis from The Cancer Genome Atlas (Ciriello et al) identifying three distinct groups within ILC based on gene expression—reactive-like, immune-related, and proliferative. In this study, we applied this 60-gene classifier to a locally advanced cohort of ILC and mixed ILC/IDC cases from patients screening for the I-SPY 2 neoadjuvant chemotherapy trial.

**Methods:** The I-SPY 2 TRIAL is open to women with more locally advanced, clinically/molecularly (as assessed by MammaPrint) high risk breast cancer. HR+HER2- MammaPrint Low risk patients ineligible for I-SPY 2 randomization are invited to join a MP Low risk registry. 131 ILC and mixed ILC/IDC tumors from these cohorts (I-SPY 2: n=80; low risk registry: n=51) with pre-treatment Agilent microarrays were available for analysis. We used the Classification to Nearest Centroid technique to assign TCGA subtype to our cohort. We assessed association between TCGA subtype, clinical covariates and response to therapy using a chi-square test. We also evaluated the Euclidean distance between each sample and the three subtype centroids. In an exploratory analysis, we used consensus clustering based on the 1000 most varying genes within the HR+HER2- I-SPY ILC cases to generate new unsupervised groupings, and assessed the concordance with the TCGA reactive-like, immune-related and proliferative subtype assignments.

**Results:** Of the 131 patients included, most (79%) were HR+HER2-, 11% were HR+HER2+, 2% were HR-HER2+ and 8% were HR-HER2- for a total of 10% HR-. 66 were pure ILC, while 65 were mixed ILC/IDC. Upon applying the TCGA 60-gene classifier, the distribution of ILC subtypes was as follows: 33 (25%) were classified as reactive-like, 50 (38%) were immune-related, and 48 (37%) were proliferative. 64% of triple negative cases were reactive-like; while the HR+HER2- and HER2+ cases were more likely to be in the proliferative or immune-related subtype (p=0.037). Among the 80 I-SPY 2 cases, the overall pathologic complete response rate was low (16%) but equivalent to the overall HR+HER2- I-SPY2 population (16%). This did not differ across the groups defined by the TCGA ILC subtypes (p=0.79).

Interestingly, a subset of cases assigned as reactive-like and immune-related were of similar distance to the proliferative subtype centroid as patients assigned to the proliferative subtype. When we used consensus clustering to identify new subsets within our locally advanced ILC cohort, our unsupervised groupings had only 32% concordance with the TCGA ILC subtype assignments.

**Conclusion:** The low concordance between our consensus cluster groupings and the TCGA subtype groupings may reflect underlying differences within a locally advanced cohort of ILC cases, like I-SPY, that may not be captured in the 60-gene classifier developed from the overall lower stage TCGA cohort. These findings suggest that considerable molecular heterogeneity exists in lobular cancers, which merits further investigation.
Synergistic targeting of CDK4/6 and BCL-2 pathways in estrogen receptor positive breast cancer

James R Whittle¹,²,³, Francois Vaillant¹, Antonia N Policheni¹, Kevin Liu¹, Bhupinder Pal¹,², Goknur Giner¹, Kristine Fernandez⁴,⁵, Daniel HD Gray¹,³, C Elizabeth Caldon⁴,⁵, Gordon K Smyth¹, Jane E Visvader¹,³ and Geoffrey J Lindeman¹,²,³. ¹The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia; ²The Peter MacCallum Cancer Centre, Melbourne, Australia; ³The University of Melbourne, Melbourne, Australia; ⁴The Garvan Institute of Medical Research, Sydney, Australia and ⁵The University of New South Wales, Sydney, Australia.

Background: Despite incremental advances in chemotherapy and endocrine therapy, survival outcomes for patients with ER-positive (ER+) metastatic breast cancer (MBC) remain poor. The majority of relapsing tumors exhibit deregulation of the cyclin-dependent kinase 4 and 6 (CDK4/6)/cyclin D1 (CCND1)/Rb signaling pathway. CDK4/6 inhibitors (such as palbociclib) in combination with endocrine therapy have been shown to significantly improve progression free survival in patients who are in 1st or 2nd line relapse, although overall survival benefit has yet to be demonstrated. This may reflect their largely cytostatic mechanism of action, with minimal induction of tumor cell death. Thus, combinatorial strategies that also induce apoptosis could be beneficial. Notably, the pro-survival protein BCL-2 is overexpressed in the majority of ER+ tumors and the potent and specific BCL-2 inhibitor venetoclax (ABT-199) has been found to synergize with endocrine therapy in patient derived xenograft (PDX) models. Promising activity has also been observed in an early phase clinical trial. We therefore investigated dual targeting of the CDK4/6 and BCL-2 pathways in pre-clinical models of ER+ and BCL-2+ breast cancer.

Results: We first examined endocrine sensitive or resistant cell-lines and found that pro-survival BCL-2 proteins were upregulated in resistant cells. BCL-2 family protein levels were also found to be elevated in palbociclib resistant cells, suggesting that BCL-2 could represent a therapeutic target. We next determined whether venetoclax improved response to dual therapy comprising the selective estrogen receptor degrader fulvestrant and palbociclib. In clonogenic assays of endocrine sensitive breast cancer cell lines, triple therapy containing venetoclax significantly reduced the number and size of colonies, when compared to double therapy. The addition of venetoclax to fulvestrant/palbociclib also augmented cell death in tumor organoid models derived from either ER+ BCL-2+ primary tumors or PDX models. Moreover, triple therapy improved tumor response and overall survival in mice bearing ER+ BCL-2+ PDX tumors. Mechanistically, this was accompanied by increased apoptosis and reduced cellular proliferation (as determined by cleaved caspase-3 and Ki67 levels, respectively). As CDK4/6 inhibitors have recently been shown to promote anti-tumor immunity, we evaluated immune modulation using the ER+ 67NR cell line in a syngeneic (BALB/c) mouse mammary tumor model. Similar to the PDX models, triple therapy comprising fulvestrant, palbociclib and venetoclax was more effective than double therapy comprising either fulvestrant/palbociclib or fulvestrant/venetoclax. Flow cytometric analysis of tumors revealed that this was accompanied by a reduced intratumoral FOXP3⁺:cytotoxic CD8 T-cell ratio.

Conclusions: The addition of the BCL-2 inhibitor venetoclax to conventional therapy comprising endocrine therapy and a CDK4/6 inhibitor augments tumor response and elicits a favorable intratumoral immune profile. Collectively, these findings support investigation of combination therapy in the clinic for patients with ER+ BCL-2+ MBC.
Immune checkpoint upregulation and T-cell exhaustion in aggressive hormone-receptor positive breast cancer patients

Meenakshi Anurag¹,², Suhas Vasaikar¹, Xiang Zhang¹, Bing Zhang¹,² and Matthew J Ellis¹,².¹Baylor College of Medicine, Houston and ²Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston.

Background: Early reports from studies focused on assessing the clinical efficacy for immune-checkpoint (IC) inhibitors in breast cancer suggest lower activity than in cancers caused by exogenous mutagens such as melanoma and smoking-related lung cancer. Nonetheless, triple negative breast cancer is under active investigation. In contrast, estrogen receptor positive disease has been considered “immunologically silent” with very few IC studies focused on this disease subset. We therefore undertook an analysis of ER+ breast cancer to determine if there are subsets of patients with poor prognosis ER+ disease that exhibit IC pathway upregulation hence potential candidates for IC-based clinical trials.

Methods: In an unbiased integrative analysis of patient samples, mRNA expression data for ~15500 genes across 66 Luminal B patient set was used to identify genes for which the expression correlated positively with proliferation marker Ki67 (in aromatase-inhibitor treated tumors) and were upregulated (>2 fold) in endocrine-therapy (ET) resistant samples as compared against the sensitive counterparts. Resulting genes were queried to identify underlying activated pathways and prioritize genes for further analysis. Validation of shortlisted genes was performed on independent patient cohorts (TCGA and METABRIC) using Kaplan-Meier disease-specific survival analysis. Amplification and methylation data for TCGA samples were obtained from CBioportal and Wanderer respectively. Proteomics data for TCGA samples was extracted using LikedOmics server. T-cell activation (TCA) and exhaustion (TCE) scores were devised using mean of standardized expression of genes reported to contribute in these two T cell states.

Result: Approximately 30 genes were found to be deferentially upregulated in ET-resistant aggressive ER+ breast cancer. This gene set was enriched in immune-tolerance biological processes (p<0.005). The three immune-checkpoints constituting these processes are IDO1, LAG3 and PDCD1 (PD1). Upregulation of IDO1 was a confirmed poor prognosis factor across independent patient cohorts. Furthermore, comparative analysis of TCA and TCE scores between ET-resistant and sensitive tumors revealed that resistant tumors have high TCE, despite having high TCA, hence circumventing immunogenic apoptosis.

Conclusion: To date, no substantial study showing prognostic relevance of mRNA levels of ICs in context of ER+ breast cancer patients has been reported. Higher IDO1 and T-cell exhaustion levels in ET-resistant ER+ disease provides clinical evidence for a role for immune-checkpoints in evading immune-driven cell death. These results suggest a potential for IC targeted immunotherapy for ~ 80% of endocrine therapy resistant clinically aggressive ER+ breast cancers.
Lasofoxifene decreases breast cancer lung and liver metastasis in a mammary intraductal (MIND) xenograft model of mutant ERα+ breast cancer

Muriel Laine¹, Marianne Greene¹, Ya-Fang Chang¹, Linda Phung¹, Richard Hiipakka¹, Barry Komm² and Geoffrey L Greene¹. ¹University of Chicago, Chicago, IL and ²Independent Consultant, Newtown Square, PA.

The standard of care for early postmenopausal ERα+ breast cancer patients is adjuvant endocrine therapy, typically an aromatase inhibitor or tamoxifen, and endocrine therapy with or without a CDK 4/6 inhibitor in the metastatic setting. However, a number of these patients are not sensitive to endocrine therapy or experience breast cancer recurrence 10 to 15 years after endocrine treatment, and all eventually progress in the metastatic setting. Metastasis of ER+ therapy-resistant breast cancer correlates with the acquisition of ESR1 activating mutations in up to 40% or more of affected patients. The two most common ERα mutations are Y537S and D538G, both of which confer ERα constitutive activity. Lasofoxifene is a SERM originally developed to treat vulvovaginal atrophy and osteoporosis. In this study, we analyzed the efficacy of lasofoxifene in the treatment of MCF7 tumor explant models that were engineered with CRISPR/Cas9 to express Y537S or D538G ERα. To better mimic the natural micro-environment of infiltrating ductal breast cancer, we used the mammary intraductal mouse model (MIND), in which tumor cells are introduced into the ducts via the nipple. Three MCF7 cell variants, MCF7 WT, MCF7 Y537S and MCF7 D538G were injected into the mammary ducts of NSG mice. Prior to injection, cells were labeled with a luciferase reporter to monitor tumor growth in vivo using a Xenogen IVIS imager. Mice were treated with three different doses of lasofoxifene (1, 5 and 10mg/kg; 5days/wk SQ), vehicle, or the SERD, fulvestrant, (5 mg SQ once per week = 250 mg/kg). After 70 days of treatment, primary tumor growth, as measured by endpoint tumor weight, of MCF7 WT, D538G and Y537S explants was significantly inhibited versus vehicle by 10 mg/kg lasofoxifene and fulvestrant. Compared to fulvestrant, lasofoxifene was significantly more effective at 5 and 10 mg/kg for the MCF7 Y537S and D538G tumors. Notably, the two MCF7 mutants metastasized to the lung and liver, whereas WT MCF-7 cells were only very weakly metastatic by the end of the study. Lasofoxifene significantly inhibited the metastasis of both MCF7 Y537S and D538G to the lungs and liver at 5 and 10 mg/ml. In contrast, fulvestrant only inhibited metastasis of the MCF7 D538G mutant to both organs. In a follow-up combination therapy study of MCF-7 WT and Y537S tumor explants, in which mice were co-treated with either fulvestrant and palbociclib or lasofoxifene and palbociclib, lasofoxifene plus palbociclib demonstrated a better outcome than fulvestrant and palbociclib in terms of primary tumor weight inhibition. Results for lung and liver metastasis inhibition are forthcoming. In conclusion, these data suggest that lasofoxifene may have the potential to be utilized as a treatment for metastatic breast cancers, including those that express constitutively active ERα mutations, including D538G and Y537S, and warrants further study.
Neoadjuvant trial with letrozole identifies \textit{PRR11} in 17q21-23 amplicon as a resistance mechanism to endocrine therapy in ER-positive breast cancer

Kyung-min Lee\textsuperscript{1}, Angel Guerrero-Zotano\textsuperscript{2}, Luigi Formisano\textsuperscript{2}, Valerie Jansen\textsuperscript{2}, Paula Gonzalez Ericsson\textsuperscript{3} and Carlos Arteaga\textsuperscript{1}.

\textsuperscript{1}Simmons Cancer Center, UT Southwestern Medical Center, Dallas; \textsuperscript{2}Vanderbilt University Medical Center, Nashville and \textsuperscript{3}Vanderbilt Ingram Cancer Center, Vanderbilt University Medical Center, Nashville.

Approximately 20\% of patients with early ER+ breast cancer (BC) treated with adjuvant antiestrogen therapy relapse with metastatic disease. Previously, we identified 3 amplicons (11q11.3, 8p11.23, and 17q21-23) associated with endocrine-resistance (Giltnane \textit{et al}. \textit{Sci Transl Med} 2017). The 17q21-23 amplicon has been associated with highly proliferative luminal B tumors and cancers with high genomic instability. A causal role of this region in endocrine resistance is unclear. We performed whole transcriptome analysis on RNA extracted from 58 ER+ breast cancers of patients treated with letrozole for 5.4-9.2 months (median 7.2 months). \textit{PRR11} (Proline rich 11), located in 17q21-23, was significantly upregulated in non-responding tumors as defined by cancer relapse after a median follow up of 5 years and/or a preoperative endocrine prognostic index (PEPI) ≥4.

Differential gene expression analysis between tumors expressing low vs high \textit{PRR11} mRNA showed that BC signatures associated with proliferation, cell cycle, IGF-1 and PI3K signaling were enriched in tumors with high \textit{PRR11} expression. In the Metastatic Breast Cancer Project and TCGA, \textit{PRR11} amplification was higher in metastatic vs. primary BCs (16.5\% and 8.5\%, respectively; Fisher's \(p=0.0088\)). Gene Set Enrichment Analysis of mRNA expression in METABRIC and TCGA revealed significant enrichment of hallmark gene sets associated with proliferation in \textit{PRR11} amplified ER+ BCs. Genome-scale RNAi screening in Project Achilles showed that among all genes in the 17q21-23 amplicon, \textit{PRR11} knockdown results in the 4\textsuperscript{th} strongest anti-proliferative effect in MCF7 cells. \textit{PRR11} knockdown with siRNA inhibited proliferation, cell cycle progression, and RB phosphorylation in HCC1428 LTED (long-term estrogen deprived), MCF7 LTED, and fulvestrant-resistant MCF7 cells. Using a PCR array with 84-cell cycle genes, we identified \textit{SKP2, CDKN1A, CCNB2, CCNA2, CKS2} and \textit{CCNB1} as genes downregulated by \textit{PRR11} knockdown. Except for \textit{CDKN1A}, expression of all those genes was elevated ER+ BCs with \textit{PRR11} gain or amplification in TCGA. \textit{PRR11} associates with the p85 regulatory subunit of PI3K via its SH3 domain. We speculated this association would suppress p85 homodimers, thus permitting binding of PI3K\(\alpha\) (p110\(\alpha\))-p85 dimers to IRS1 and, hence, activating PI3K/AKT. To test this, we co-transfected HEK293T cells with HA-p85 and FLAG-p85. Transfection of \textit{PRR11} into these HEK293T cells reduced HA-p85 and FLAG-p85 homodimers as shown by HA and FLAG pulldowns followed by FLAG and HA immunoblots, respectively. Finally, \textit{PRR11} knockdown resulted in a reduction of p110a and S473 P-AKT levels and inhibition of IGF-1/2 stimulated P-AKT. Not inconsistent with these data, \textit{PRR11} amplification and \textit{PIK3CA} mutations in METABRIC and TCGA are exclusive of each other, suggesting these alterations are functionally linked with the same signaling pathway. These data support a role of \textit{PRR11} in PI3K/AKT activation that may be causal to resistance to estrogen deprivation. We propose \textit{PRR11}, located in the 17q21-23 amplicon, is a potential mediator of resistance to antiestrogen therapy by amplifying PI3K/AKT signaling, suggesting PI3K may be a therapeutic target in ER+ BCs harboring \textit{PRR11} amplification.
Therapeutic strategy for ESR1 mutation driven-endocrine resistance in ER-positive breast cancers

Jin-Ah Kim¹, Derek Dustin¹, Guowei Gu¹, Arnoldo Corona-Rodriguez¹, David Edwards¹, Cristian Coarfa¹, Khandan Keyomarsi² and Suzanne AW Fuqua¹. ¹Baylor College of Medicine, Houston, TX and ²M.D. Anderson Cancer Center, Houston, TX.

Background: Endocrine therapy is used in estrogen receptor (ER)-positive breast cancers, however, 25% of these patients are at risk of distant relapse and the development of acquired endocrine resistance. Recently mutations in the ER gene (ESR1) have been validated to be acquired during the development of endocrine resistance. The most frequent ESR1 mutation, Y537S, promotes ligand-independent ER activity and emerges subclonally during aromatase inhibitor treatment. In this study, we examined the effects of the Y537S ESR1 mutation on cell cycle signaling and therapeutic response to a novel checkpoint inhibitor.

Material and Methods: MCF-7 cells expressing the Y537S ESR1 mutation were generated by CRISPR-Cas9 knock-in techniques. Cells were incubated in steroid deprived conditions. Cell cycle analysis and apoptosis were examined by flow cytometry annexin-V assays. Proliferation was analyzed by BrdU incorporation. Cell cycle checkpoint kinases were examined by western blot analysis. Cell growth was analyzed using soft agar and MTT assays. Replication stress was identified by RPA32 and gamma-H2AX foci formation assay. For in vivo studies, MCF-7 ESR1 Y537S mutant cells were injected into female athymic nude mice with 17β-estradiol (E2) supplemented water. When tumors reached 350 mm³, tamoxifen (20 mg/kg; s.c.; three times a week), fulvestrant (200 mg/kg; s.c; once a week) and/or PF477736 Chk1 inhibitor (7.5 mg/kg; i.p.; twice a day and twice a week) was treated without E2.

Results: ESR1 Y537S mutant cells accumulated approximately 5 fold in S phase and 1.7 fold in G2/M phase compared to control cells in estrogen-deprived (ED) conditions. BrdU incorporation also increased about 2.5-fold, however, apoptosis was decreased about 60 % compared with wild-type ER parental cells. ESR1 Y537S mutant cells induced significant replication stress, showing increased RPA32 foci together with increased gamma H2AX foci, a marker of DNA double-stranded breaks. ChIP-seq analysis revealed binding sites on ATR and CHEK1 genomic locations. ATR/Chk1-mediated checkpoint signaling was activated in ESR1 Y537S mutant cells, and was repressed with fulvestrant, tamoxifen, or ESR1 siRNA treatment. The Chk1 inhibitor, PF477736, sensitized MCF-7 expressing the ESR1 Y537S mutation to endocrine treatments such as fulvestrant, tamoxifen, and the ER degrader AZD9496 in cell proliferation assays. In MCF-7 ESR1 Y537S mutant xenograft and patient derived mouse models, tamoxifen treatment combined with the Chk1 inhibitor PF477736 repressed primary xenograft tumor doubling times (P=0.038, Wilcoxon test). Treatment of mutant tumors with PF477736 together with fulvestrant significantly inhibited the frequency of distant lung metastases by 80% (P=0.0031, t-test), suggesting that these combinations may be useful in second line treatment of metastatic breast cancer patients resistant to endocrine therapies.

Conclusion: These preclinical results suggest that ESR1 mutant tumors have a therapeutic vulnerability to combination endocrine therapy with cell cycle checkpoint kinase inhibitors. These data demonstrate that this new therapeutic approach may be useful to restore endocrine sensitivity in metastatic breast cancer patients with ESR1 mutation driven-endocrine resistance.
Inhibition of CDK7 overcomes resistance to CDK4/6 inhibitors in hormone receptor positive breast cancer cells

Cristina Guarducci1,2, Agostina Nardone1,2, Ariel Feiglin3, Ileneia Migliaccio4, Luca Malorni4,5, Martina Bonechi4, Matteo Benelli6, Angelo Di Leo4,5, Graeme Hodgson7, Geoffrey Shapiro8, Myles Brown1,2,9 and Rinath Jeselsohn1,2,9. 1Dana Farber Cancer Institute, Boston, MA; 2Center for Functional Cancer Epigenetics, Dana Farber Cancer Institute, Boston, MA; 3Harvard Medical School, Boston, MA; 4Sandro Pitigliani Translational Research Unit, Hospital of Prato, Prato, Italy; 5Sandro Pitigliani Medical Oncology Department, Hospital of Prato, Prato, Italy; 6Bioinformatics Unit, Hospital of Prato, Prato, Italy; 7Syros Pharmaceutical, Cambridge, MA; 8Early Drug Development Center, Dana-Farber Cancer Institute, Boston, MA and 9Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

Background: Despite the efficacy of the combinations of endocrine therapy (ET) and CDK4/6 inhibitors in the hormone receptor positive (HR+) metastatic breast cancer (BC) setting, the majority of patients eventually acquire resistance to these treatments. The loss of Rb activity is an important mechanism of acquired resistance to CDK4/6 inhibitors. Preclinical and clinical data support the RB1 genetic aberrations, including mutations and deletions with loss of expression, as mechanism of palbociclib (palbo) resistance. To study vulnerabilities and potential treatment targets to overcome resistance to CDK4/6 inhibitors associated with Rb loss we studied a T47D palbo-resistant (T47D PDR) HR+ BC cell model obtained by exposing palbo-sensitive cells to increasing concentrations of palbo. These cells harbour deletion of RB1, and show increased cyclin E1 and decreased ER expression.

Methods: To identify genes that are essential for cell growth and genes whose loss enhances cell growth in palbo-resistant cells with loss of Rb, we performed genome-wide CRISPR-Cas9 knockout (KO) screens in T47D palbo-sensitive (T47D PDS) and T47D PDR cells. We searched for significantly essential genes that are targets with available drugs and tested the efficacy of these compounds in T47D PDS and T47D PDR cells.

Results: By employing a genome wide CRISPR KO screen, we identified 29 genes that were significantly positively selected in the T47D PDR cells. Among these genes were known tumor suppressor genes, such as TSC2 (β score: 0.89) and PTEN (β score: 0.68). We identified close to 600 genes that were significantly essential (negatively selected) for T47D PDR growth. CDK4, CDK6 and CCND1 were essential in the T47D PDS parental cells but lost essentiality with the acquisition of palbo resistance (FDR> 0.05). CDK7 (β score: -1.21) and CDK2 (β score: -1.67) were among the top ranked essential genes (FDR: 0). CDK7 is a transcriptional CDK and has CDK activating kinase (CAK) activity. The CAK activity includes phosphorylation of CDK2 and CDK9. To follow up on our CRISPR screen results we tested the activity of the selective CDK7 inhibitors SY-1365 (currently in phase 1 clinical development) and THZ1 in the T47D PDS and T47D PDR cells. We saw dose dependent activity in both cell line models. Moreover, the IC50 values were comparable in T47D PDS and T47D PDR cells (THZ1; PDS: 9.93 nM, PDR with Palbo: 32.8 nM, PDR without Palbo: 1.08 nM) (SY1365; PDS: 1.60 nM, PDR with Palbo: 6.70 nM, PDR without Palbo: 1.87 nM). Combination studies of SY-1365 and fulvestrant in T47D PDR showed synergistic activity at lower concentrations.

Conclusions: In a model of palbo resistance with loss of Rb we found that cyclin D1, CDK4 and CDK6 are not essential, suggesting cross-resistance to other CDK4/6 inhibitors in this setting. We identified CDK7 as a significant essential gene and potential therapeutic target. We validated these findings with the selective CDK7 inhibitors, THZ1 and SY-1365. Our results offer a new therapeutic strategy for the treatment of palbo-resistant HR+ BC.
Microscopic extracapsular extension in sentinel lymph nodes does not mandate axillary dissection in Z0011-eligible patients

Andrea V Barrio¹, Stephanie Downs-Canner¹, Hiram S Cody¹, Kimberly J Van Zee¹, Mary L Gemignani¹, Melissa Pilewskie¹, George Plitas¹, Mahmoud El-Tamer¹, Laurie Kirstein¹, Deborah Capko¹, Sujata Patil¹ and Monica Morrow¹. 'Memorial Sloan Kettering Cancer Center, New York, NY.

Background
In ACOSOG Z0011 and AMAROS, matted nodes with gross extracapsular extension (ECE)—a risk factor for locoregional recurrence—were an indication for axillary dissection (ALND), but the effect of microscopic ECE (mECE) in the sentinel nodes (SLNs) on recurrence was not examined.

Methods
Between 2010-2017, 815 patients with cT1-2N0 breast cancer and SLN metastasis were prospectively managed according to Z0011 criteria, with ALND for those with >2 positive SLNs. Management of mECE was not specified. Here we report outcomes of patients with 1-2 positive SLNs treated with SLN biopsy alone (n=685) and evaluate the impact of mECE on nodal recurrence. Outcomes of the 118 patients treated with ALND, of which 70% had >2 positive SLNs, are provided for comparison.

Results
Median patient age was 58 years and median tumor size was 1.7 cm. In the SLN group, 210 (31%) had mECE. Patients with mECE were older, had larger tumors, were more likely to be hormone receptor positive (HR+) and HER2-, have 2 positive SLNs, and to receive nodal radiation (Table).

At a median follow-up of 41 months, no isolated axillary failures were observed. There were 11 nodal recurrences; 2 isolated, 4 synchronous with breast, and 5 with distant failure. The 5-year rate of any nodal recurrence was 1.6% and did not differ by mECE (2.3% vs 1.3%, p=0.84). No differences were observed in local (0% mECE vs. 1.9% no mECE, p=0.08) or distant (1.2% mECE vs. 4.6% no mECE, p=0.31) recurrence rates by mECE status. In comparison, in the 118 patients having ALND, 101 (86%) had mECE, and 1 combined nodal and distant recurrence was seen.

Conclusions

In Z0011-eligible patients, rates of nodal recurrence in patients with mECE are low after treatment with SLN biopsy alone, even in the absence of routine nodal radiation. The presence of mECE should not be considered a routine indication for ALND.
Residual axillary involvement in early breast cancer in patients with positive sentinel nodes after neoadjuvant chemotherapy (NACT)

Hans-Christian Kolberg¹, Cornelia Liedtke², Ingo Bauerfeind³, Tanja Fehm⁴, Barbara Fleige⁵, Maik Hauschild⁶, Gisela Helms⁷, Annette Lebeau⁸, Sabine Schmatloch⁹, Peter Schrenk¹⁰, Lukas Schwentner¹¹, Annette Stäbler⁷, Sibylle Loibl¹², Michael Untch⁵ and Thorsten Kühn¹³. ¹Marienhospital Bottrop, Bottrop, Germany; ²Charité - Universitätsmedizin Berlin, Berlin, Germany; ³Klinikum Landshut, Landshut, Germany; ⁴Universitätsklinikum Düsseldorf, Düsseldorf, Germany; ⁵Helios-Klinikum Berlin-Buch, Berlin, Germany; ⁶Spital Rheinfelden, Rheinfelden, Switzerland; ⁷Universitätsklinikum Tübingen, Tübingen, Germany; ⁸Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; ⁹Elisabeth-Krankenhaus Kassel, Kassel, Germany; ¹⁰Kepler Universitätsklinikum, Linz, Austria; ¹¹Gynova, Reith, Austria; ¹²German Breast Group, Neu-Isenburg, Germany and ¹³Klinikum Esslingen, Esslingen, Germany.

Background: The association between pathological complete remission (pCR) in the breast and clinical/pathological parameters is well established, whereas the role of these parameters in the prediction of residual axillary involvement after NACT is unclear. The goal is to identify a subset of patients who do not need axillary treatment. We used data from Arm B of the SENTINA trial to analyze this association.

Methods: Patients from arm B of the SENTINA trial with clinically and sonographically unsuspicious axillary nodes but with histologically proven involvement of SLNs prior to NACT were analyzed. All patients had SLNB and axillary dissection after NACT. Univariate analyses were performed to evaluate the association between clinical/pathological parameters and axillary involvement after NACT.

Results: Arm B of the SENTINA study contained 360 patients, 318 of which were evaluable with respect to the above parameters. After NACT 71/318 (22.3%) patients had involved SLNs or non-SLNs; 71/318 (22.3%) had a pCR in the breast. We observed a significant association between pCR in the breast and negative ER status, negative PR status, positive HER2 status, triple negative (TN) status, tumor size before and after NACT, multifocality, lobular morphology and axillary involvement after NACT. Regarding residual axillary burden only the associations with lobular morphology, extracapsular invasion, multifocality, positive HER2 status and pCR in the breast were statistically significant.

Conclusion: Our analysis demonstrates that patients enrolled in the SENTINA trial with clinically and sonographically unsuspicious axillary nodes but proven histological involvement of SLNs prior to NACT have positive axillary nodes in 22.3 % after NACT. This rate is confirming similar results from other groups. Although we found statistically significant associations between pCR in the breast and clinical/pathological parameters, only the association between lobular type, extracapsular invasion, positive HER2 status and pCR in the breast and residual axillary involvement after NACT were statistically significant. We cannot clearly identify a subset of patients for whom axillary treatment after NACT could be safely omitted if SLNs were positive. Our data are well in line with recently presented data demonstrating that the association between pCR in the breast and free axillary nodes after NACT is particularly strong in patients with TN and HER2 positive tumors. This question will be addressed in future trials currently under development.
Conversion rates from positive to negative axillary involvement in breast cancer patients presenting with biopsy-proven axillary metastases prior to primary systemic therapy (PST) – A transSENTINA subproject

Cornelia Liedtke¹, Hans-Christian Kolberg², Maja Krajewska¹, Ingo Bauerfeind³, Tanja Fehm⁴, Barbara Fleige⁵, Gisela Helms⁶, Annette Lebeau⁷, Annette Staebler⁷, Sibylle Loibl⁸, Michael Untch⁹ and Thorsten Kühn⁹. ¹Charite Hospital Berlin, Berlin, Germany; ²Marienhospital Bottrop, Bottrop, Germany; ³Klinikum Landshut, Landshut, Germany; ⁴Universitätsklinikum Düsseldorf, Düsseldorf, Germany; ⁵Helios-Klinikum, Berlin-Buch, Germany; ⁶Universitätsklinikum Tübingen, Tübingen, Germany; ⁷Universitätsklinikum Eppendorf, Hamburg, Germany; ⁸German Breast Group, Neu-Isenburg, Germany and ⁹Klinikum Esslingen, Esslingen, Germany.

Background:
Modern chemotherapy carries a high potential of converting patients with clinically suspicious axillary nodes (cN+) prior to PST to clinically (ycN0) or pathologically (ypN0) negative nodes after PST. Clinical and sonographical axillary assessment, however, may be inadequate and therefore pathological assessment of suspicious axillary nodes is recommended. We analyzed the association between clinical / pathological parameters and positive to negative conversion in patients with biopsy-proven axillary metastases in Arm C of the SENTINA trial (i.e. patients with “true conversion”).

Methods:
Arm C of the SENTINA trial included patients converting from cN+ to ycN0 through PST from a prospective study. We limited our analysis to patients who had biopsy-proven axillary involvement. Univariate regression analysis was carried out to assess the association between patients with vs. without axillary disease after PST in i) patients with biopsy-proven involvement and ii) patients without biopsy proof of metastases.

Results:
Among 596 patients in arm C of the SENTINA trial with clinically and or sonographically suspicious ipsilateral axillary nodes, 439 (73.7%) 157 (26.3%) patients had a biopsy. In 152 patients (96.8%), lymph node metastases were confirmed and in 5 patients (3.2%), no malignant cells were identified. In both groups, we found a significant association (p<0.05) between increased rate of axillary conversion and small tumor diameter after PST, absence of multifocality, absence of lymphovascular invasion (LVI), ER and/or PR negativity, HER2 negativity, triple negative disease, and complete pathological response (pCR). No multiple testing corrections were performed due to an exploratory setting. However, only among patients with biopsy-proven involvement prior to PST, we found grade-3-tumors to be significantly associated with reduced probability of residual axillary involvement (76.1 vs. 33.8%, compared to G1 and G2, p=0.0323).

Conclusion:
Our analysis demonstrates that in patients with biopsy-proven axillary involvement before NST, parameters associated with axillary conversion are similar to those among patients classified as having nodal disease based on clinical and or sonographical assessment (cN+). Our analyses demonstrate that in biopsy-proven axillary metastases before NST, modern chemotherapy regimens result in significant rates of axillary conversion. This underscores the need to deescalate axillary staging / treatment with the goal to further avoid unnecessary axillary surgery.
Neoadjuvant chemotherapy for breast cancer: Nodal downstaging is highly correlated with pathological complete response

Peter Blumencranz¹, Mehran Habibi², Tina Treece³, Lisa Blumencranz³, Erin Yoder³, William Audeh⁴, Ebonie Carter⁴, Lauren McNaughton⁴, Julia Roussos⁴, Steve Shivers⁴, Geza Acs⁵, Charles Cox⁴ and MINT Investigators Group³. ¹Morton Plant Hospital, Clearwater, FL; ²Johns Hopkins Breast Center at Bayview, Baltimore, MD; ³Agendia, Inc, Irvine, CA; ⁴University of South Florida, Tampa, FL and ⁵Florida Hospital Tampa, Tampa, FL.

**Background:** Neoadjuvant chemotherapy (NAC) is employed in patients with larger tumors to attempt to downstage locally advanced cancers to allow breast conservation and to assess in vivo tumor response. The Multi-Institutional Neoadjuvant Therapy MammaPrint Project I (MINT) study asked a secondary question of whether complete nodal downstaging could also be achieved with NAC.

**Methods:** This analysis included 147 eligible invasive breast cancer patients with high tumor burdens, classified as cT2-4N0-3M0 (T2 greater than 3.5cm if N0). Patients who had a positive core biopsy and/or fine needle aspiration (FNA) on an axillary node prior to starting NAC were included in this analysis. Those who had a surgical sentinel lymph node biopsy were not included. Nodal involvement was established following neoadjuvant treatment by axillary lymph node dissection (ALND).

**Results:** This population was 54% postmenopausal, average age 53 yrs (range 25 to 80 yrs). Tumor characteristics were 91% invasive ductal carcinoma; 65% T2, 29% T3, 6% T4; 87% LN1, 13% LN2-3; 3% low grade, 38% intermediate grade, 59% high grade; 65% ER-positive, 49% PR-positive, and 28% HER2-positive by immunohistochemistry; 84% High Risk (HR) and 16% Low Risk (LR) by MammaPrint (MP). After NAC, 45% (66/147) of these LN-positive patients were down-staged to ypN0 and also achieved a complete pathological response in the primary tumor.

The potential for down-staging was inversely-related to tumor burden, where 47% (60/128) of N1, 35% (6/17) of N2, and 0% (0/2) of N3 patients were down-staged to ypN0. There were 3 patients who were down-staged (2 N2 to N1, and 1 N3 to N2), but not to ypN0. At surgery, 34% (44/128) of patients had no change, and 19% (24/129) progressed in LN staging.

**Conclusions:** We confirmed that upon achieving a complete response of the primary tumor that there was also a pathologic complete response in the LN. About 53% of patients had no change or progression of LN involvement following NAC.
Background: Role of additional axillary treatment (AxT) (axillary lymph node dissection (ALND) or axillary radiotherapy (ART)) in women with ≤2 macrometastases and undergoing systemic therapy remains unclear. Z11 included both micro and macrometastases (around 40% micrometastases) and showed that ALND may be omitted in women with ≤2 positive nodes undergoing breast conserving surgery (BCS) and receiving whole breast RT. Paradoxically, NCIC MA20, demonstrated improved DFS following the addition of regional RT. 51.8% (949/1832) had 1 or 2 positive nodes. 98.9% (1812/1832) had T1/T2 tumours. A post-Z11 survey shows that most US radiation oncologists treat the undissected axilla in women with macrometastases with ART rather than omitting AxT. Therefore, a confirmatory study is needed to clarify the role of additional AxT in women with ≤2 macrometastases undergoing BCS and other subgroups that were not included in Z11 e.g. mastectomy, microscopic extranodal invasion and sentinel node biopsy (SNB) before neoadjuvant chemotherapy.

Methods: Primary objective is to assess whether for women with ≤2 macrometastases at SNB, systemic therapy alone is non-inferior to systemic therapy plus AxT in terms of axillary recurrence at 5 years. Secondary objectives are arm morbidity assessed by LBCQ and QuickDASH questionnaires; QoL assessed by FACT-B+4 questionnaire; anxiety assessed by STAI; loco-regional recurrence; distant metastasis; time to axillary recurrence; axillary recurrence-free survival; DFS; OS; contralateral breast cancer; non-breast malignancy; and economic evaluation. Eligibility criteria include: ≥18 y, uni or multifocal invasive cancer, T1/T2, 1 or 2 macrometastases, with or without extranodal invasion. Target sample size is 1900 with a projected drop-out and non-compliance with treatment allocation rate of 10%. Primary analysis will be per protocol. The following pre-specified subgroup analyses shall be performed: number of macrometastases (1, 2), age (<50, ≥50), breast surgery (mastectomy, BCS), ER (positive, negative), tumour grade (1 or 2, 3), SN assessment technique (OSNA, non-OSNA), extranodal invasion (present, absent). POSNOC opened to recruitment in July 2014. To date 1100 women have been recruited at 82 sites in the UK and 18 sites in Australia and New Zealand. Clinicaltrials.gov NCT02401685.
Fluorescence guided breast conserving surgery

Chitresh K Sharma, Piyush Ranjan, Darakshan Qaiser, Anita Dhar, Anurag Srivastava and Kamal Kataria. 1All India Institute of Medical Sciences, New Delhi, Delhi, India.

Background. Palpation guided breast conserving surgery for breast cancer is associated with tumor involved margins in up to 41% of cases. Ultrasound guided breast conserving surgery and frozen section biopsy result in a significant reduction in margin positivity. However, intra-operative USG and Frozen section biopsy are not widely available. We aimed to find a simple and effective technique for intra-operative margin assessment during breast conserving surgery.

Hypothesis. Intravenously injected Fluorescein reaches tumor tissue in high concentration due to increased tumor blood flow and increased capillary permeability which can be detected by blue light (494 nm).

Objective. To find diagnostic accuracy of fluorescence guided identification of tumor margins during breast conserving surgery.

Methods. A total of 60 patients with T1–T2 invasive breast cancer who underwent breast conserving surgery at AIIMS, New Delhi between March, 2016 to Feb, 2018 were included. Each patient received 2 ml of intra-venous 20% Fluorescein sodium just before skin incision. Breast conserving surgery was performed under USG guidance. Specimen was bisected and examined under blue light. Fluorescent tumor margins were identified and six biopsies taken from non-fluorescent area 5mm outside from fluorescent tumor margins at 2,4,6,8,10 and 12 o’clock position. The involvement of USG guided margin was compared with Fluorescence guided margins on histopathology.

Results. Mean age of the patient was 51.2 (SD=6.4) years. Fourteen patients (20.3 %) had T1 tumors while 46 patients(69.7%) had T2 tumors. Axillary nodes were involved in 19 patients (20.1%) and all underwent axillary node dissection. Eight patients (13.3%) received NACT. Fluorescent margins in two (3.3%) out of 60 patients were involved by tumor while USG guided margins in all the 60 patients were free. The specificity of fluorescence in identifying uninvolved tumor margins during breast conserving surgery is 96.7%.

No patient developed adverse drug reactions.

Conclusion. The fluorescence identifies tumor free margins with 96.7% accuracy. It is simple, effective and affordable method of identifying margin positivity in breast conservation surgery.
Does resection of cavity shave margins result in lower positive margin and re-excision rates in patients with stage 0-III breast cancer? Results from a prospective multicenter randomized controlled trial

Annees B Chagpar¹, Theodore Tsangaris², Carlos Garcia-Cantu³, Marissa Howard-McNatt⁴, Akiko Chiba⁴, Adam C Berger², Edward Levine⁵, Jennifer S Gass⁵, Kristalyn Gallagher⁶, Sharon S Lum⁷, Ricardo D Martinez⁸, Alliric I Willis², Sonali V Pandya⁵, Eric A Brown⁵, Andrew Fenton⁶, Amanda Mendiola⁶, Mary Murray⁶, Victor Haddad⁵, Naveenraj L Solomon¹, Mahenswari Senthil⁷, Hannah Bansil⁶, David Ollila¹, Samuel K Snyder³, David Edmonson⁵, Melissa Lazar², Jukes P Namm⁷, Fangyong Li¹, Meghan Butler¹, Noreen E McGowan¹⁰, Maria E Herrera⁵, Yoana P Avitan⁶, Brian Yoder¹¹ and Elisabeth Dupont¹⁰. ¹Yale University, New Haven, CT; ²Thomas Jefferson University, Philadelphia, PA; ³Doctors Hospital at Renaissance, Edinburg, TX; ⁴Wake Forest University, Winston-Salem, NC; ⁵Women and Infants Hospital, Providence, RI; ⁶University of North Carolina, Chapel Hill, NC; ⁷Loma Linda University, Loma Linda, CA; ⁸Beaumont Hospital, Troy, MI; ⁹Cleveland Clinic Akron General, Akron, OH; ¹⁰Watson Clinic, Lakeland, FL and ¹¹MicroPath Laboratories, Lakeland, FL.

INTRODUCTION: Routine resection of cavity shave margins has been shown in single center studies to result in a significant reduction in positive margin and re-excision rates. In this prospective multicenter randomized controlled trial, we sought to validate these findings across practice settings.

METHODS: Nine centers across the United States, varying in practice setting and patient population, participated in this clinical trial of 398 stage 0-III breast cancer patients undergoing partial mastectomy (with or without resection of selective cavity margins). Participants were stratified by clinical stage and randomized 1:1 to either have routine cavity shave margins resected (“shave”) or not (“no shave”). Randomization group was revealed to the surgeon intraoperatively, after they had completed their standard partial mastectomy and were ready to close. Positive margins were defined as “tumor at ink” for invasive cancer or within 2 mm for ductal carcinoma in situ (DCIS). Adverse events were defined as seromas requiring percutaneous drainage, and/or hematomas or abscesses requiring operative intervention.

RESULTS: Median patient age was 65 (range; 29-94). 116 patients had invasive disease, 74 had DCIS, 179 had both, and 29 had no residual cancer at the time of partial mastectomy. The median invasive cancer size was 1.2 cm (range; 0.05-8.00 cm); the median extent of DCIS was 0.9 cm (range; 0.05-6.40 cm). The “shave” and “no shave” groups were well matched at baseline for clinicopathologic and demographic factors.

Prior to randomization, positive margin rates were similar in the “shave” and “no shave” groups (38.1% vs. 37.3%, respectively, p=0.918). After randomization, however, those in the “shave” group were significantly less likely than those in the “no shave” group to have positive margins (8.6% vs. 37.3%, respectively, p<0.001). They were also less likely to require re-excision or mastectomy for margin clearance (8.6% vs. 23.9%, p<0.001). There were no significant differences between the two groups in terms of adverse events (p=0.280). Rates of seroma (1.5% vs. 0.5%, p=0.368), hematoma (0.5% vs. 0.5%, p=1.000) and abscess (0.3% vs. 0%, p=0.495) were similar between the “shave” and “no shave” groups, respectively.

**CONCLUSION:** Resection of cavity shave margins significantly reduces positive margin and re-excision rates in patients with stage 0-III breast cancer undergoing partial mastectomy.
Development of humanized immune DCIS models using patient peripheral blood derived hematopoietic stem cells (CD34+)

Fariba Behbod1, Haleigh Harper1, Hayley Hansford1, Darlene Limback1, Yan Hong1, Hanan Elsarraji1, Lawrence R Ricci2, Fang Fan1, Ossama Tawfik3, Lisa May4, Therese Cusick4, Marc Inciardi1, Mark Redick1, Jason Gatewood1, Onalisa Winblad1, Timothy A Fields1, Carol Fabian1, Andrew K Godwin1, Patrick E Fields1, Ruby Meierotto3 and John Perry5. 1University of Kansas Medical Center, Kansas City, KS; 2Truman Medical Center, Kansas City, MO; 3St. Luke's Health System, Kansas City, MO; 4University of Kansas School of Medicine-Wichita, Wichita, KS and 5Stowers Institute, Kansas City, MO.

Background:
Ductal carcinoma in situ (DCIS) is the most common form of non-invasive breast cancer. To accurately study the natural progression of DCIS lesions in mice, we devised the mouse-intraductal (MIND) animal model, which involves intraductal injection of human DCIS epithelial cells into the mammary ducts of immunocompromised mice. To improve the translational application of the MIND model, we aimed to mimic the natural microenvironment of human DCIS with patient-derived immune cells and assess the role of engrafted immune cells on human DCIS progression. In order to achieve successful engraftment of the entire immune system in mice, we utilized MISTRG mice. These mice were developed by Rongvaux et al., on an immunodeficient (Rag2−/−IL2rγ−/−) background. The genes encoding human M-CSF (M), human IL-3 (I), SIRP1α (S), human thrombopoietin (TPO)(TR), and GM-CSF (G) were knocked into their respective mouse loci. As such, MISTRG mice are highly permissive for human hematopoiesis, supporting the development and function of lymphocytes, monocytes, and natural killer (NK) cells. In contrast, previous studies have used the humanized CD34+ NOD-SCID IL2rγ−/− mice (CD34+NSG), which are unable to support myeloid cell differentiation due to lack of expression of human-specific cytokines. Moreover, prior xenograft studies in the CD34+NSG mice have not used immune cells derived from the same patient as the tumor.

Results:
Human CD34+ cells derived from patients’ peripheral blood were expanded ex vivo ~100-fold using a novel formulation of culture medium. Transplantation of ex vivo expanded CD34+ cells via tail vein injection of MISTRG mice resulted in the successful engraftment of human immune cells as early as 4 weeks following injection. Successful engraftment was confirmed by flow cytometry using human specific antibodies that recognize human leukocytes (anti-CD45), T cells (anti-CD3), B cells (anti-CD20), and myeloid cells (anti-CD33) in spleen, bone marrow, and peripheral blood of MISTRG mice. Once engraftment was confirmed, DCIS epithelial cells from the same DCIS patients or DCIS cell lines were injected intraductally. Recruitment of patient-derived immune cells to the DCIS lesions was confirmed by immunofluorescence using human-specific antibodies that recognize neutrophils (anti-myeloperoxidase), macrophages (anti-CD68), M2-polarized macrophages (anti-c-MAF), natural killer cells (anti-CD56), dendritic cells (anti-CD21), T cells (anti-CD3) and B cells (anti-CD20).

Conclusion:
This model represents the first to enable the study of mechanisms of DCIS progression in a manner that fully represents the heterogeneity of human disease, including the influence of the patients’ own immune cells on DCIS progression.
Approximately 40% of invasive recurrences after treatment of ductal carcinoma in situ is likely to be a second primary tumor.

**Background.** Ductal carcinoma in situ (DCIS) is a potential precursor of invasive breast cancer, because: DCIS often accompanies invasive breast cancer; its risk factors are similar to those of invasive breast cancer; and genetic markers found in DCIS are similar to the ones found in invasive breast cancer. However, clinical behavior of DCIS is still poorly understood, as there is only limited information on its long-term natural history. Altogether, this makes it difficult to understand the relatedness of DCIS and its subsequent ipsilateral invasive breast cancer (iIBC). Here, we set-up a comparison between primary DCIS and matched subsequent iIBC, by making use of pathological and molecular data.

**Patients and methods.** For this study, we used a unique series of 155 DCIS cases which developed a subsequent iIBC during a median follow up period of 12.6 years. We assessed histological characteristics, tumor location, estrogen and progesterone receptor status, p16 expression, and HER2 and p53 overexpression. RNA sequencing and copy number sequencing was done on 78 DCIS lesions and 78 matched invasive breast cancer relapses. We determined if the iIBC lesion and DCIS lesion were related, with respect to tumor location, immunohistochemical (IHC) markers, and genomic features.

**Results.** Based on tumor location and histological grade, >95% of the subsequent invasive breast cancers reflected outgrowth of residual disease. HER2 was the only IHC marker that showed a significant difference in expression between DCIS and matched iIBC: 40% of the HER2 positive DCIS was followed by a HER2 negative invasive recurrence. In addition, RNAseq data was used to classify DCIS and IBC lesions into PAM50 subtypes. 77% of the DCIS IBC pair belonged to the same subtype. The DCIS lesions showed copy number aberrations on typical breast cancer-associated loci. However, when we compared the DCIS with its matched iIBC, we saw in 41% of the cases very distinct copy number profiles, indicating either outgrow of a different tumor subclone or a second primary.

**Conclusion.** This is the first time that a sound comparison could be made between primary DCIS and its subsequent invasive breast cancer with such a large patient group, integrating pathological and molecular data. Our results strongly suggest that many subsequent iIBCs after treatment of pure DCIS could be considered as second primary breast cancer lesions. To provide definite proof for this, in depth DNA sequencing and heterogeneity studies will be presented at SABCS 2018.
No increased cardiovascular mortality after twenty years in a randomized trial of radiotherapy after breast conserving surgery, SweBCG 91RT, from the Swedish breast cancer group

Per Malmström¹, Per Karlsson², Erik Holmberg³, Dan Lundstedt², Lars Holmberg⁴, Linda Werner-Hartman⁵, Sacha Koul⁶, Elisabeth Kjellén¹ and Fredrika Killander¹. ¹IKVL Lund, Oncology and Pathology, Lund University, Skåne University Hospital, Lund, Sweden; ²Sahlgrenska Academy, Sahlgrenska University Hospital, Göteborg, Sweden; ³Regional Cancer Center West, Sahlgrenska University Hospital, Göteborg, Sweden; ⁴Sahlgrenska University Hospital, Göteborg, Sweden; ⁵Uppsala University, Uppsala, Sweden; ⁶Lund University, Lund, Sweden and ⁷Skåne University Hospital, Lund, Sweden.

Introduction
Breast conserving surgery (BCS) with postoperative radiotherapy (RT) is recommended for the majority of patients with early breast cancer. Meta-analyses of randomized trials have shown reduction of breast cancer and overall mortality after RT but increased cardiovascular mortality.

Aim
To evaluate side effects of RT after BCS

Patients and Methods
Trial SweBCG 91RT randomized 1187 women with stage 1-IIA breast cancer after BCS to RT or to no further treatment. RT was administered as tangential opposing beams to the breast to a target dose of 48-54 Gy. Three-dimensional dose planning on multiple CT slices 10 mm apart was used for 69% of the patients and for the remainder two-dimensional planning. All hospital records and radiotherapy charts were monitored. Update of mortality, cause of death and morbidity was made using the Swedish personal identification numbers and the following Swedish national registers: the Cancer Register, the Population Register, the Cause of Death Register, the Inpatient and the SWEDEHEART registers. For analyses the diagnoses were grouped as follows: breast cancer, cardiovascular disease, cerebrovascular disease, lung cancer and benign pulmonary disease.

Statistics
Overall mortality was calculated using the Kaplan-Meier method, whereas cumulative incidence functions with other causes of death as competing events were used for cause-specific mortality and morbidities. For all outcomes, log-rank tests were used to compare between treatment groups up to 20 years. We studied two populations: 1) patients according to intention to treat for overall and breast cancer mortality and 2) patients treated per protocol for side effects. Cause-specific death was allocated to a certain group when either the underlying or a contributing cause belonged to the disease group.

Results
After 20 years, overall mortality was 42.9% after BCS and 42.5% after BCS+RT (p=0.8), and breast cancer mortality was 18.0% vs 15.8% (p=0.3). The cumulative incidence of mortality from heart disease was 12.4% after BCS and 13.0% after BCS+RT (p=0.8) with no difference for left or right side. Ischemic heart disease and congestive heart failure were the most common cardiac diagnoses. The cumulative incidence of cerebrovascular mortality was 3.4% among controls and 6.7% after RT (p=0.016). Of the patients with cerebrovascular death, 50% also had a cardiac cause of death. Other cause-specific mortalities investigated were similar regardless of RT: lung cancer 1.7% vs 1.9% (p=1.0), benign pulmonary disease 7.1% vs 6.4% (p=0.5).

Morbidity
Morbidity outcomes were also similar in control and irradiated patients: the cumulative incidence of hospital admissions with cardiac diagnoses 29.7% vs 31.0% (p=0.7), and for cerebrovascular morbidity 11.6% vs 13.7% (p=0.33) respectively.

Radiation exposure
The original dose plans were retrieved from 125 patients. Doses to organs at risk were recalculated. Median of mean heart dose was 3.0 Gy (1.1-8.2) for left and 1.0 Gy (0.5-2.5) for right-sided RT.

Conclusions
After 20 years tangential RT in a randomized trial was not associated with increased cardiac mortality. A minor increase in cerebrovascular mortality was seen, but the causality is unclear.
Distribution of locoregional breast cancer recurrences in relation to previous radiotherapy and biological subtype

Jamila Adra¹, Per Karlsson¹, Fredrika Killander², Dan Lundstedt¹ and Sara Alkner². ¹Institute of Clinical Sciences, Sahlgrenska Academy/Sahlgrenska University Hospital, University of Gothenburg, Gothenburg, Sweden and ²Lund University, Faculty of Medicine, Lund, Sweden.

**Background:** Adjuvant locoregional radiotherapy (LRRT) reduces risk of locoregional failures (LRF) and improves survival for node positive breast cancer (BC) patients. However, LRRT increases the risk for toxicity as edema in the arm, lung cancer and cardiac mortality. Modern radiotherapy allows a more conform therapy which makes knowledge of LRF-patterns very important, in order not to underdose volumes with high risk for microscopic disease and simultaneously restrict dose to risk organs. In addition, BC-subtype may affect radiosensitivity and could possibly be used to individualize LRRT in the future.

**Methods:** We investigated outcome for BC-patients receiving LRRT in the Southwest Sweden (2004-2008) in order to identify LRFs. During this period patients with >3 positive lymph nodes were given LRRT (50Gy in 2Gy fractions) to the breast/thoracic wall, axilla level II+III, supra- and infraclavicular lymph nodes according to a target definition atlas introduced in 2002. Patients with LRF as first event were identified, with distant failures and death considered as competing risks. The anatomical distribution of LRF was compared with the contouring atlas, radiotherapy given, and biological subtype based on immunohistochemistry.

**Results:** 904 patients received LRRT. Median follow-up time was 9.8 years (0.2-14.6) for patients without an event. 59 patients (6.5%) developed a LRF, 30 of which were local failures (LF) and 31 regional failures (RF) (2 simultaneous LF/RF). Median time to LRF was 2.8 years. 37 of the 59 (63%) LRF-patients developed generalized disease within 3 months from the LRF. Of the 845 patients without LRF 316 developed distant metastases as first recurrence, 1 an isolated RF in the contralateral axilla, 64 died from other causes, and for 5 patients recurrence-status was unclear. 459 were alive at end of follow-up.

Of the LF 19 developed after mastectomy (MRM) and 11 after breast conserving surgery (BCS). LF-location after MRM: 9 in-field, 6 at field margin, 2 both in/out of field, 1 out of field, and for 1 not yet determined. After BCS: 8 in-field, 1 at field margin, and for 2 not yet determined. Of the RF 28 developed after MRM and 3 after BCS. Location of RF after MRM: 11 in-field, 6 at field margin, 1 both in/out of field, 2 out of field, and for 8 not yet determined. After BCS: 1 in-field, 1 at field margin, and 1 not yet determined. The most common location for RF close to /out of field was superior to the treated area in fossa supraclavicularis.

Biological approximate subtype was available for 885 of the primary tumours; luminal (ER+ and/or PR+ HER2-/?) 67% (589/885), HER2+ 19% (169/885), triple negative (ER- and PR- HER2-/?) (TN) 14% (127/885). Subtype distribution of BC later causing LRF despite LRRT was: luminal 44% (26/59), HER2+ 27% (16/59), TN 29% (17/59). Among primary tumours causing a LRF within irradiated volume 77% (24/31) were HER2+ or TN.

**Conclusion:** In this high risk cohort of BC-patients, we found a low incidence of LRFs. The majority of LRFs developed within irradiated volume. BCs of the HER2+ and TN-subtype may be more radioresistant and have a higher risk of LRF. Updated information as well as figures mapping all recurrences in relation to previous LRRT will be presented at the symposium.
Safety and efficacy of palbociclib and radiotherapy in metastatic breast cancer patients: Initial results of a novel combination

Mudit Chowdhary¹, Neilayan Sen¹, Akansha Chowdhary², Lydia Usha¹, Melody Cobleigh¹, Kirtesh R Patel³, Dian Wang¹, Parul N Barry¹ and Ruta D Rao¹. ¹Rush University Medical Center, Chicago, IL; ²Northwestern University School of Medicine, Chicago, IL and ³Yale School of Medicine, New Haven, CT.

Purpose: Palbociclib is a selective CDK4/6 inhibitor approved for the treatment of metastatic ER+/HER2- breast cancer. Inhibition of CDK4/6 prevents cell cycle progression from G1 to the more radioresistant S phase, raising the possibility of an enhanced therapeutic effect if combined with radiotherapy (RT). Despite this potential benefit, clinicians seldom use this combination due to fear that RT may exacerbate palbociclib toxicity, particularly leukopenia. Our aim is to report the preliminary results of patients with metastatic breast cancer who received RT while receiving palbociclib.

Methods: We retrospectively reviewed records of all patients who were treated with palbociclib at our institution from 2015-2018. Patients who received RT for symptomatic metastases concurrently or within 14 days of last drug administration were included in our analysis. Local treatment effect was assessed by clinical exam and subsequent CT or MRI imaging, if applicable. Toxicity was graded based on CTCAE v5.0.

Results: A total of 16 females received palliative RT in association with palbociclib. The median age of the treated patients was 59.6 (range 33.3-91.0) years. The median time of closest palbociclib use to RT administration was 5 (range 0-14) days. The following sites were treated in order of frequency: bone (10-axial skeleton [8-vertebra]; 1-ilium), brain (4: 3-WBRT & 1-SRS), and mediastinum (1). RT dose/fractionation for bone was 30 Gy/10 fxn (7), 35 Gy/14 fxn (2), 37.5 Gy/15 fxn (1), and 18 Gy/1 fxn (1). WBRT dose/fractionation was 30 Gy/10 fxn for all patients. SRS brain dose was 25 Gy/5 fxn. The patient treated to the mediastinum received 36 Gy/18 fxn.

At most recent follow-up, 12 patients are still living. The median time from RT to last known follow-up or death is 10.3 (range 1.7-29.6) months. Pain relief was achieved in 15 of 16 (93.8%) patients. No radiographic local failure was noted in the 13 patients with evaluable follow-up imaging.

The combination of RT and palbociclib was well-tolerated. Grade 1 fatigue, dermatitis, and nausea was noted in 5, 3, and 1 patient, respectively. One patient with WBRT developed Grade 1 headache. Six of 16 patients were leukopenic prior to RT initiation. Following RT, 7 patients were observed to have a drop in WBC count, of which 2 dropped into the leukopenic range. Only a total of 5 patients were leukopenic following RT, of which 3 were leukopenic before receiving RT. No acute or late Grade 2 or higher cutaneous, neurological, gastrointestinal, or hematologic toxicities were noted.

Conclusions: The use of RT in patients receiving palbociclib resulted in minimal Grade 1 and no Grade 2+ toxicities, including leukopenia. This treatment can be used safely in symptomatic patients without discontinuation of systemic therapy. Further larger prospective studies with longer follow-up are needed to confirm these results.
Genomic alterations associated with loss of HR expression in metastatic breast cancer

Ana C Garrido-Castro¹, Melissa E Hughes¹, Andrew Cherniack², Romualdo Barroso-Sousa¹, Brittany L Bychkovsky¹, Simona Di Lascio³, Ashton Berger², Elizabeth A Mittendorf¹, Janet L Files¹, Hao Guo⁴, Priti Kumari⁴, Ethan Cerami⁴, Ian E Krop¹, Nikhil Wagle¹,⁵,⁶, Neal I Lindeman⁵,⁶, Laura E MacConaill⁵,⁶, Deborah A Dillon⁴, Eric P Winer¹ and Nancy U Lin¹. ¹Dana-Farber Cancer Institute; Harvard Medical School, Boston, MA; ²Broad Institute of MIT and Harvard, Boston, MA; ³Oncology Institute of Southern Switzerland, Bellinzona, Switzerland; ⁴Dana-Farber Cancer Institute, Boston, MA; ⁵Brigham and Women’s Hospital; Harvard Medical School, Boston, MA and ⁶Center for Cancer Genome Discovery, Dana-Farber Cancer Institute, Boston, MA.

Background: Discordance in hormone receptor (HR) status between primary (p) tumors and metastatic (m) recurrences has been widely described. Loss of estrogen and progesterone receptor expression occurs in ~12% of asynchronous recurrences, leading to triple-negative (TN) status in the metastasis. Genomic mechanisms driving HR loss and its prognostic and therapeutic implications have not been fully elucidated.

Methods: Targeted NGS (Oncopanel, OP) at Dana-Farber Cancer Institute using multiplexed copy number variation and mutation (mut) detection across the full coding regions of 300 genes and selected intronic regions of 35 genes was prospectively performed on either archival primary or metastatic samples collected in patients (pts) with metastatic breast cancer (MBC). Receptor status at initial diagnosis and recurrence were reviewed using a 1% cutoff to define HR-positivity and excluding HER2+ cases. Fisher’s exact test was used to compare frequency of alterations. Tumor mut burden (TMB) was computed normalizing the sum of reported exon mut in each pt by the exonic-bait-set size of the panel.

Results: Between 8/2013-9/2016, 929 pts with MBC underwent OP testing. Of 517 pts diagnosed with primary HR+/HER2-breast cancer, at time of recurrence 388 remained HR+/HER2- (pHR+/mHR+), 39 switched to HR-/HER2- (pHR+/mTN, of which 23 (59%) had initial HR expression >10%), 10 switched to HER2+ and 80 had unknown metastatic receptor status. Comparison between primary samples in pHR+/mHR+ (n=245) and pHR+/mTN (n=24) showed that pHR+/mTN was significantly more likely to harbor mut in \textit{TP53}, \textit{STK11} and \textit{MSH6}, amplifications (amp) in \textit{CCNE1} and \textit{FGFR2}, and less likely to have \textit{PIK3CA} mut or \textit{CCND1} amp.

Median TMB in primary pHR+/mHR+ was 6.05 mut/Mb (0-37.5) and 5.68 mut/Mb (1.2-10.9) in pHR+/mTN (p=0.45). Metastatic samples in pHR+/mTN (n=15) were enriched in \textit{ARID1A}, \textit{CRTC2} and \textit{CDH1} mut compared to metastases (n=40) in pts who remained TN (pTN/mTN). Deletions in \textit{CDKN2A/2B} and \textit{RB1}, and mut in \textit{TP53}, \textit{NOTCH2} and \textit{ERCC2} were more prevalent in recurrent tumors of pHR+/mTN than pHR+/mHR+. In metastases, TMB was higher in pHR+/mTN than pTN/mTN or pHR+/mHR+.
Median OS from initial diagnosis was 9.4 yrs in pH+ mTN, less than pH+/mHR+ (15.9 yrs; p=0.009) and greater than pTN/mTN (4.3 yrs; p=0.008). Median OS from MBC diagnosis was 1.8 yrs in pH+/mTN, less than pH+/mHR+ (6.4 yrs; p=0.001) but not significantly different than pTN/mTN (1.5 yrs, p=0.3).

**Conclusion:** Targeted NGS shows that alterations in DNA damage and cell-cycle regulation pathways in primary HR+ tumors are associated with HR loss in the metastatic setting. Primary tumors that lose HR appear more similar to basal-like than luminal tumors, despite >10% baseline HR expression in most pts, and once metastatic, survival is comparable to pTN/mTN. Metastases with HR loss have higher TMB than those that remain HR+ or TN throughout the course of the disease. These findings, if confirmed, may influence treatment and pt selection for clinical trials.
Evolutionary analysis of 462 serial metastatic biopsies from 208 patients with estrogen receptor-positive (ER+) metastatic breast cancer (MBC) using whole exome sequencing (WES)

Ofir Cohen¹,²,³, Jorge Buendia-Buendia¹,²,³, Seth Wander¹,²,³, Utthara Nayar¹,²,³, Pingping Mao¹,²,³, Ada Waks¹,²,³,⁴, Dewey Kim¹,²,³, Samuel Freeman¹, Viktor Adalsteinsson¹, Karla Helvie²,³, Dimitri Livitz¹, Daniel Rosebrock¹, Ignaty Leshchiner¹, Laura Dellostritto²,³, Ana Garrido-Castro²,³, Esha Jain¹,²,³, Shreemiyad Periyasamy²,³, Colin Mackichan²,³, Max Lloyd²,³, Lori Marini²,³,⁴, Ian Krop²,³, Levi Garraway²,³, Gad Getz¹,², Eric Winer¹,²,³, Nancy Lin¹,²,³ and Nikhil Wagle¹,²,³,⁴. ¹Broad Institute of MIT and Harvard, Cambridge, MA; ²Dana-Farber Cancer Institute, Boston, MA; ³Harvard Medical School, Boston, MA; ⁴Brigham and Women’s Hospital, Boston, MA and ⁵Massachusetts General Hospital Cancer Center, Charlestown, MA.

Background: While great strides have been made in the treatment of ER+ MBC, therapeutic resistance is nearly universal. The genomic evolution of ER+ breast cancer in the metastatic setting under the selective pressure of multiple lines of therapies is not well understood. To address this, we analyzed the clonal dynamics of serial metastatic samples (mets) to evaluate how tumors evolve and to identify acquired resistance mechanisms.

Methods: We performed WES on 462 clinically annotated samples from 208 patients (pts) with ER+ MBC, including 67 primary tumor biopsies, 229 metastatic biopsies and 160 blood samples (cfDNA). Pts with multiple mets included cases with temporally concordant metastatic tumor and blood samples (48 pts) and cases with serial mets obtained over the course of treatment in the metastatic setting (69 pts). Treatments given between the serial mets included CDK4/6 inhibitors (23 pts), and selective estrogen receptor degraders (19 pts), among others.

Results: In the temporally-concordant mets, we found that cfDNA mutations (muts) largely overlap with muts found in tumor biopsies, capturing >85% of clonal tumor muts. However, we observed a higher level of heterogeneity in cfDNA compared to biopsies (p.value< 1.05e-19, Welch test) and a subset of high-confidence muts that were only detected in cfDNA, including in clinically important genes such as ESR1, PIK3CA, KRAS, and ERBB2. Analysis of serial mets was used to elucidate the evolutionary dynamics within the metastatic setting under the selective pressure of treatment. The median duration between mets was 112 days and the median number of inter-biopsy unique treatments was two. Most tumors continued to evolve within the metastatic setting, with 50 out of 69 pts (72%) acquiring a meaningful sub-clone (50% increase in relative cancer cell fraction) and 31 out of 69 (45%) acquiring muts in known cancer genes, including a subset acquiring a plausible resistance alteration such as alterations that dysregulate ER (5 out of 69 pts, 7%; ESR1 mut, FOXA1 amplification (amp), NCOR1 bi-allelic deletion (del)), ERBB (4%; EBB2 amp, ERBB3 mut), RAS (4%; KRAS mut, NRAS amp, NF1 del), FGF/FGFR (12%; FGFR2 mut, FGFR1/2 amp, FGF3 amp), and cell cycle (13%; RB1 del, CDK4 amp, AURKA amp, CDKN2A del). Finally, in pts who had multiple mets, we observed several cases of evolutionary convergence toward equivalent resistance mechanisms including convergent RB1 loss as a mechanism of resistance to a CDK4/6 inhibitor and convergent BRCA2 reversion following resistance to a PARP inhibitor.

Conclusions: This study demonstrates that ER+ MBC continues to evolve under the selective pressure of treatments in the metastatic setting. These findings elucidate the challenge of studying high complexity and heavily treated tumors, while also highlighting some commonalities in the evolutionary trajectories selected by these treatments. The multiplicity of clinically relevant genomic alterations acquired in these advanced stages highlights the need for serial biopsies and the potential to inform post-progression therapeutic choices through targeting the acquired dependencies in post-progression tumors.
The genomic landscape of de novo metastatic breast cancer (MBC)

Esha Jain¹, Dewey Kim¹, Jorge Buendia Buendia¹, Ofir Cohen¹, Romualdo Barroso Sousa², Elana Anastasio¹, Micheal Dunphy¹, Mary McGillicuddy¹, Rachel Stoddard¹, Sara Balch¹, Beena Thomas¹, Simona Di Lascio², Brett N Tomson¹, Colleen Nguyen¹, Corrie Painter¹ and Nikhil Wagle². ¹The Broad Institute of MIT and Harvard, Cambridge, MA and ²Dana Farber Cancer Institute, Boston, MA.

Background: Approximately 5-10% of newly diagnosed breast cancers (BC) are de novo MBC, which means that metastatic disease was identified at the time of initial diagnosis. Patients with de novo MBC are underrepresented in currently available genomic studies. In The Cancer Genome Atlas (TCGA) dataset, only 15 out of ~980 BC patients can be classified as having de novo MBC. The objective of this study is to analyze the genomic landscape of de novo MBC and to study the genomic differences of this cohort with early stage BC. To enhance our ability to study de novo MBC, we utilized data from the Metastatic Breast Cancer Project (MBCproject), a patient-partnered research project that aims to generate a large public database of clinical, genomic, and patient reported data (PRD) from patients with MBC.

Methods: We defined de novo MBC as patients diagnosed with metastatic disease less than 4 months after their initial diagnosis with BC. Out of 127 patients in the MBCproject with publicly released whole exome sequencing (WES) data, we identified 33 patients with de novo MBC. We combined this data with 15 de novo MBC patients in TCGA. For patients with de novo MBC with multiple tumor biopsies available, we used WES from breast biopsies to enable appropriate comparison to the early stage biopsies. Somatic mutations were evaluated and significantly recurring genes were identified using MutSig2CV. We compared the mutations found in the de novo cohort with early stage tumors. 10 patients in the de novo MBC cohort had paired simultaneous primary and metastatic biopsies; genomic alterations in these samples were compared. Finally, we used RNA sequencing data to compare cytolytic signatures among the de novo and early stage biopsies.

Results: Among the 48 patients analyzed the receptor subtype distribution was: HR+/HER2-(23), HR+/HER2+(13), HR-/HER2+(2), HR-/HER2-(3), HR+/HER2 unknown(5), and HR-/HER2 unknown(2). Histology subtype distribution was as follows: IDC(39), MDLC(6), ILC(2) and Other (1). Significantly recurrent genes in the de novo MBC cohort (q<0.1) included TP53 (27%), PIK3CA (30%), CDH1 (8%) and MAP3K1 (11%). Mutations in PTEN, EGFR, and MDM4 were significantly enriched (p<0.05) in the de novo cohort when compared to early stage BC.

Evolutionary analysis of paired primary and metastatic biopsies for de novo MBC patients demonstrated the presence of shared clonal mutations, indicating that these were highly evolutionarily related. RNA-seq immune cytolytic signature was downregulated in de novo MBC as compared to early stage BC (p<0.2).

Conclusions: Our initial results highlight genomic differences between de novo MBC and early stage BC, including increased frequency of PTEN, EGFR, and MDM4 mutations. Enrichment of PTEN mutations (implicated in tumor immune surveillance), and downregulation of cytolytic signature potentially suggests that de novo MBC may have immunosuppressive tumor microenvironment. To date, ~1200 patients with self-reported de novo MBC have registered for the MBCproject. We anticipate that additional study of genomic and clinical data from these patients will greatly improve our understanding of de novo MBC.
FGFR4 as a key regulator of HER2E subtype in the primary and metastatic setting

Susana Garcia Recio¹,², Joel S Parker¹,², Cheng Fan¹,², Kevin Mott¹,², Xiaping He¹,², Juan M Cejalvo¹¹,¹², Fara Brasó Maristany¹¹,¹², Patricia Galván¹¹,¹², Ana Lluch³,⁴,⁵, Joan Albanell³,⁴,⁶,⁷,⁸, Federico Rojo³,⁴,⁹, Eduardo Martínez de Dueñas³,⁴,¹⁰, Aleix Prat¹¹,¹² and Charles M Perou¹,².¹ Lineberger Comprehensive Center, University of North Carolina, Chapel Hill, NC; ²University of North Carolina, Chapel Hill, NC; ³GEICAM (Grupo GEICAM de Investigación en Cáncer de Mama), Madrid, Spain; ⁴Centro de Investigación Biomédica en Red de Oncología, CIBERONC-ISCIII, Madrid, Spain; ⁵Hospital Clínico Universitario de Valencia, Valencia, Spain; ⁶IMIM Hospital del Mar Medical Research Institute, Barcelona, Spain; ⁷Hospital del Mar, Barcelona, Spain; ⁸Universitat Pompeu Fabra, Barcelona, Spain; ⁹Fundación Jiménez Díaz, Madrid, Spain; ¹⁰Hospital Provincial de Castellón, Castellón, Spain; ¹¹Translational Genomics and Targeted Therapeutics in Oncology (IDIBAPS), Barcelona, Spain and ¹²Hospital Clinic of Barcelona, Barcelona, Spain.

Background: Therapeutic targets in TNBC remain a challenge. We have observed that some Luminal A primary breast tumors give rise to HER2-enriched (HER2E) subtype metastases but remain clinically HER2 negative (HER2E/cHER2-). Molecular features that drive these HER2E/cHER2- tumors may represent key targets of metastatic progression.

Methods: A comparative genetic and transcriptomic analysis in TCGA (1100 patients) related to the FGFR family was performed. We focused on FGFR4, in part, due to its unique association with the HER2E expression subtype and we developed a robust FGFR4-signature based upon a supervised analysis of a HER2E/cHER2- PDX (WHIM11) treated with a FGFR4 inhibitor (BLU9931). We also constructed a new Luminal Tumor Score (LTS) to identify the optimal axis of separation between Luminal A versus HER2E tumors (higher scores represent greater Luminal A phenotype). Univariate and multivariate analyses were performed using TCGA and METABRIC (1971 samples). Finally, we performed RNA-seq on a cohort of 77 matched primary breast cancer and metastatic tissues pairs from the GEICAM/2009-03 and Hospital Clinic of Barcelona study, and did multiple analyses on these cohorts using our FGFR4-signatures.

Results: FGFR4 was significantly higher in HER2E subtype (P<0.0001), independent of HER2 clinical status. FGFR4 amplification/deletions and mutations were rare and did not correlate with FGFR4 high expression. In vivo, BLU9931 treatment of WHIM11 showed a significant tumor growth inhibition (P=0.01), prolonged survival, and a significant higher LTS (P=0.016). We also identified 745 up-regulated genes called FGFR4-repressed (FGFR4-rep) and 427 down regulated genes called FGFR4-induced (FGFR4-ind), after BLU9931 treatment. Gene set enrichment analysis revealed that FGFR4-ind genes were enriched for STAT3, PI3K/AKT/mTOR pathway and KRAS activation, proliferation, hypoxia, glycolysis and metastasis. FGFR4-rep genes were involved with KRAS inhibition, cell polarity, p53 pathway and upregulation of IFNγ response. In the METABRIC cohort, FGFR4-ind and FGFR4-rep each predicted OS (HR=6.30, P<0.0001; HR=0.33; P<0.0001, respectively). Multivariate analysis showed FGFR4-ind (HR=2.34, P=0.014) as a significant independent prognostic factor beyond subtype for OS. Supervised analysis of the 77 primary-met cohort revealed that the FGFR4-ind was significantly higher in luminal metastases compared with their primaries counterparts (P<0.001), along with proliferation, angiogenesis, and a M2 macrophage signature (with most other immune features being unchanged). Finally, univariate and multivariate analysis demonstrated that the FGFR4-related signatures predicted site-specific metastasis for lung, liver and brain, but not for bone and lymph nodes.

Conclusion: FGFR4 is one of the drivers of HER2-enriched subtype tumors, including those that are clinically HER2-. The FGFR4-ind signature was predictive of worse survival, progression in the metastatic setting, and site-specific metastasis. Treatment options in HER2-enriched TNBC, and for HER2E/cHER2+ patients, may benefit from targeting FGFR4, whose high expression is not based upon genomic or genetic features.
The importance of the metastatic biopsy: Clinical and translational relevance in a real world series of patients with metastatic breast cancer

Belinda Yeo¹,²,⁴, Tahlia Molinaro¹,⁵, Delphine Merino²,³,⁴,⁵, Jean Berthelet²,⁴, Normand Poulion²,⁴, Catherine Fang², Caroline Bell² and Robin Anderson²,⁴,⁵. ¹Austin Health, Melbourne, VIC, Australia; ²Olivia Newton-John Cancer Research Institute, Melbourne, VIC, Australia; ³Walter and Eliza Hall Institute of Medical Research, Melbourne, VIC, Australia; ⁴La Trobe University, Melbourne, VIC, Australia and ⁵University of Melbourne, Melbourne, VIC, Australia.

Background
Metastatic breast cancer (MBC) is a heterogeneous disease, whose clinical course and prognosis may be unpredictable, creating significant uncertainty for patients and their families. Heterogeneity is breast cancer subtypes is now well recognized as a potential reason for treatment resistance. Sampling metastatic sites at the point of diagnosis or upon progression, when safe, is recommended to better guide therapy.

Purpose
This study evaluated patients currently undergoing treatment for MBC in the clinic to determine the clinical and translational significance of a metastatic sample.

Methods
Patients currently undergoing treatment for MBC at the Olivia Newton John Centre were identified. Data was collected on patient demographics, clinicopathological information, treatment and duration of response. Translational research tissue was collected, with consent, for DNA and RNA analysis.

Results
Between January 2017 and May 2018 111 patients were identified. The mean age of MBC diagnosis was 60 years (range 30-87), with a mean follow up time of 2.4 years (range 0.8-16). Fifteen patients died during the study period. Sixty-seven (60%) patients were initially treated for early breast cancer (EBC), with a median disease free interval (DFI) 4.7 years. Half (51%) these patients relapsed after five years.

At MBC diagnosis, multiple sites of disease were identified including bone, visceral, brain, nodal and skin/chest wall disease. Bone only disease was common (25%), whereas brain disease was rare overall (9%). Metastatic tissue was collected in 67 (60%) patients, where up to four different sites were biopsied. The most commonly biopsied site was bone (n=21), followed by soft tissue (n=20), chest wall/skin disease (n=12), liver (n=9), lung (n=8) and brain (n=8). Serous disease was collected in 16 patients, including pleural, pericardial, ascitic and cerebrospinal fluid.

Based on the EBC subtype (n=67), 70% had luminal disease, 19% had Her2 positive disease and 7% had TNBC. However, based on a metastatic biopsy (n=67), only 61% of patients had luminal disease, 21% had HER2 positive, and 18% had TNBC. Paired EBC and MBC samples were available in 48 patients, with significant change in breast cancer subtype demonstrated in 12 of these patients (25%). The most common change was a loss in ER staining, which included 6 patients from ER positive, HER2 negative to TNBC and three patients who became ER negative but remained HER2 positive. Molecular profiling was performed thus far on 8 samples at the single cell and bulk level. These results highlight a large level of inter- and intra-tumoral heterogeneity, and may result in a better understanding of the molecular pathways specifically deregulated in patients at the point of progression.

Conclusion
In this single institution series of patients with MBC, over half of the cohort underwent at least one metastatic biopsy. Strikingly, a quarter of patients demonstrated a change in their breast cancer subtype, which directly guided subsequent therapy. Metastatic tissue can provide vital information to inform treatment decisions, which may be guided by translational laboratories having access to fresh tissue at the point of metastatic diagnosis or disease progression.
Paired pre- and post-treatment DNA sequencing identifies genomic alterations mediating clinical resistance to CDK 4/6 inhibitors in patients with metastatic breast cancer

Laura M Spring¹, Stephanie Haddad¹, Giuliana Malvarosa¹, Neelima Vidula¹, Dejan Juric¹, Anthony J Iafrate¹, Leif W Ellisen¹, Beverly Moy¹, Steven J Isakoff¹ and Aditya Bardia¹. ¹Massachusetts General Hospital Cancer Center, Boston, MA.

Background: The combination of cyclin-dependent kinase 4 and 6 inhibitors (CDK 4/6 inh) and endocrine therapy have changed the treatment paradigm for hormone receptor-positive metastatic breast cancer (HR+ MBC). Three CDK 4/6 inhibitors (palbociclib, ribociclib, and abemaciclib) are now approved for HR+ MBC in combination with either an aromatase inhibitor (AI) or fulvestrant (a selective estrogen receptor degrader, SERD) after demonstrating significant improvement in progression-free survival compared to endocrine monotherapy. However, both primary and secondary resistance has been observed clinically, and the mechanisms of such resistance are not well understood. Here we describe emergence of molecular alterations following treatment with the combination of CDK 4/6 inhibitors and endocrine therapy.

Methods: We evaluated molecular alterations by next-generation sequencing (NGS) prior to and following treatment with CDK 4/6 + endocrine therapy pre and post CDK inh among patients with HR+ MBC. We performed circulating tumor (ct) DNA analysis via the Guardant360 assay, an NGS-based assay that identifies potential tumor-related (somatic) genomic alterations through sequencing of the critical exons within 73 cancer-related genes, and/or tissue-based genomic analysis utilizing our institutional NGS platform (SNaPshot), which targets hotspots and exons in 89 genes.

Results: A total of 33 HR+ MBC patients had paired pre/post CDK 4/6 tissue/liquid biopsies. 19 (57.6%) received palbociclib and 14 (42.4%) ribociclib, with 25 (75%) receiving an AI and 8 (24%) a SERD. Eight patients (24.2%) were first line. The median duration of response was 8 months (range 1-35 months). The most common acquired alterations at the time of progression that were not present in the pre-treatment specimens included mutations in ESR1 (30.3%), TP53 (30.3%), RB1 (12.1%) and PIK3CA (9.1%), and FGFR1 amplification (27.3%). We then evaluated these results in a subset of patients (N=17) who had paired pre/post liquid biopsies only and found similar results. We observed alterations in oncogenic pathways both upstream and downstream of CDK 4/6-cyclin-D complex (N=17), including upstream receptor tyrosine kinase alterations (29.4%), PI3K/AKT/mTOR alterations (5.9%), and MAPK alterations (17.6%), as well as downstream cell-cycle (35.3%) and DNA repair gene alterations (17.6%). Furthermore, 58.8% of patients had more than one acquired potential driver mutation, and 41.2% had both upstream and downstream alterations possibly reflecting emergence of different subclones and tumor heterogeneity under selective pressure from CDK 4/6 inhibitors.

Conclusion: Both upstream and downstream genomic alterations may mediate acquired clinical resistance to CDK 4/6 inhibitors, reflecting genomic evolution and diversification after exposure to CDK 4/6 inhibitors. Additional studies are needed to confirm these findings and develop potential therapeutic strategies to overcome clinical resistance to CDK 4/6 inhibitors for patients with MBC.
A phase II study of copper-depletion using tetrathiomolybdate (TM) in patients (pts) with high risk breast cancer (BC): Role of collagen processing and tumor microenvironment

Ying L Liu¹, Cecilie Liv Bager², Nicholas Willumsen³, Naomi Kornhauser¹, Marta Cobham⁴, Eleni Andreopoulou⁴, Tessa Cigler⁴, Anne Moore⁴, Dayle LaPolla⁴, Veronica Fitzpatrick¹, Maureen Ward⁴, J David Warren⁴, Vivek Mittal⁴ and Linda T Vahdat¹.
¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Nordic Bioscience - Proscion, Herley, Denmark; ³Nordic Bioscience, Herley, Denmark and ⁴Weill Cornell Medicine, New York, NY.

Background: Copper is an important catalytic cofactor in several biological functions and is essential for lysyl oxidase (LOX), a key enzyme in cross-linking collagen, which may play a role in tumor metastasis. We hypothesized that tetrathiomolybdate (TM)-associated copper depletion (CD) would inhibit tumor metastases by altering copper dependent collagen remodeling in the pre-metastatic niche. These results are an update of our previously reported clinical outcomes with longer follow-up and translational outcomes implicating the tumor microenvironment in metastatic transformation of BC.

Methods: Pts at high risk for recurrence, node+ triple negative (TNBC) or stage 3/4 BC with no evidence of disease (NED), were enrolled on a phase II study of CD with TM. TM was given to maintain ceruloplasmin (Cp) levels between 8-16 mg/dl for two years (yrs) with an extension phase or until relapse. Median Cp levels were monitored with each cycle. Clinical endpoints included safety/tolerability and progression of disease (POD)/death. Event-free (EFS) and overall survival (OS) were calculated using Kaplan Meier survival analyses. Translational endpoints included markers of collagen cross-linking (LOXL-2), formation (PRO-C3), and degradation (C1M and C6M).

Results: Seventy-five pts received 2993 cycles of TM on the primary (24 cycles, 28 days per cycle) and extension study. Median age was 51 yrs (range 29-66). Forty-five pts had stage 2/3 BC, and 30 pts were stage 4 NED. At a median follow-up of 8.4 yrs, the overall EFS was 71.4% and OS was 78.8%. The EFS and OS for the 36 pts with TNBC were 71.7% and 81%, and the EFS and OS for the 39 pts with Luminal/HER2+ BC were 71.2% and 78.6% respectively. TM was well tolerated with grade 3/4 toxicities including: neutropenia (1.9%), febrile neutropenia (0.03%), and fatigue (0.2%). LOXL2 levels were significantly decreased at 12 and 24 cycles compared with baseline (p<0.01) in those who were NED but not in those who had progressive disease (POD). LOXL2 levels were significantly correlated with C1M levels (spearman coefficient -0.34, p=0.02). C1M levels were significantly increased at 5, 11 and 24 cycles as compared with baseline (p<0.01) in those who were NED and were significantly higher as compared to levels in those experiencing POD/death, p<0.05. This difference may be more pronounced in those not achieving adequate CD (<50%) and in luminal/HER2+ BC. Interestingly, the ratio of C1M/PRO-C3 was significantly more elevated over time in those NED as compared to those experiencing POD/death. No associations were found with other collagen markers (PRO-C3 and C6M).

Conclusions: TM is safe, well-tolerated and associated with decreased LOXL-2 and increased C1M levels over time in NED pts. This suggests that copper depletion may result in decreased collagen crosslinking and increased collagen degradation over formation, potentially “normalizing” the collagen microenvironment to create an inhospitable environment for tumor metastases. Larger randomized trials in high risk populations with translational outcomes are needed to further investigate the role of collagen processing in the tumor microenvironment and its potential as a biomarker of response.
Breast cancer liver metastases vascularize by vessel co-option, not angiogenesis, and have a desert immune phenotype: A histopathological and gene expression study

Peter B Vermeulen¹, Pieter-Jan van Dam², Sofie Daelemans², Emily Latacz¹, Ines Joye¹, Mark Kockx², Piet Dirix¹, Kees Verhoef³, Dirk Grunhagen³, Philippe Huget¹, Steven Van Laere¹ and Luc Y Dirix¹. ¹GZA Hospitals Sint-Augustinus & University of Antwerp, Wilrijk, Antwerp, Belgium; ²HistoGeneX, Wilrijk, Antwerp, Belgium and ³Erasmus MC-University Medical Center, Rotterdam, Netherlands.

Phase 3 trials of bevacizumab combined with chemotherapy in metastatic breast cancer have consistently failed to demonstrate a survival benefit for the addition of bevacizumab. When cancers metastasize to highly vascular organs (including the liver), they can utilize vessel co-option, instead of angiogenesis, as a mechanism to obtain a vascular supply (1). We have repeatedly shown by histopathological analyses that almost all (95%, 2 cohorts) breast cancer liver metastases utilize vessel co-option instead of angiogenesis to vascularize (2,3). The prevalence of vessel co-option in breast cancer could explain, at least in part, why anti-angiogenic therapy has been a disappointing therapeutic approach in metastatic breast cancer. Animal models of non-angiogenic liver and lung metastases also displayed resistance to anti-VEGF treatment (3,4).

We have now undertaken a gene expression study (mRNA sequencing) of targeted samples at the tumor-liver interface to discover gene expression patterns and signaling pathways that are associated with non-angiogenic growth of metastatic cancer in the liver (n = 70). A network to detect biological themes of non-angiogenic growth was built by gene set enrichment analysis. Key components of this network are: cancer cell motility and invasion, epithelial-to-mesenchymal transition, stemness and proliferation. This contrasts with the network of angiogenic liver metastases of which the most important components are inflammation and ECM remodeling. Semi-automated image analyses of CD8-immunostained section of liver metastases confirms that non-angiogenic liver metastases have a significantly lower density of CD8-positive cytotoxic T-lymphocytes at the tumor-liver interface when compared with angiogenic liver metastases (300 cells/mm² and 1000 cells/mm², respectively (p<0.0001)). In addition, a clear CXCL13-driven B-cell gene expression signature is associated with angiogenic growth of liver mets but is absent in non-angiogenic growth of breast cancer liver metastases. Gene expression patterns that may play a role in vessel co-option are the up-regulation of LAMA3, LAMB3, LAMC2, coding for the 3 subunits of laminin-5, and of ITGA3, ITGB1, ITGA6 and ITGB4, coding for both integrin-receptors of laminin-5. This supports the concept of ‘adhesive’ vessel co-option during which cancer cells use the basement membrane of the co-opted blood vessels as a soil (5). In addition, the claudin-2 gene (CLDN2) is significantly overexpressed in non-angiogenic liver metastases which is consistent with earlier reports on the role of claudin-2 during breast cancer metastasis to the liver (6).

In conclusion, we provide evidence, based on morphology and gene expression, for the almost exclusive non-angiogenic growth of breast cancer liver metastases. In addition, non-angiogenic breast cancer liver metastases are characterized by a desert immune phenotype. Both observations can have an impact on the treatment strategy of patients with metastatic breast cancer. Tumor microenvironment (TME) plays a central role in the development of distant metastasis. However, given its complexity, successful targeting of TME will require a detailed understanding of its composition. Cancer-associated fibroblasts represent a large component of TME and are a major contributor to the extracellular matrix (ECM). Previously, we demonstrated the presence of two fibroblast sub-populations (CDCP1\(^{pos}\) vs CD146\(^{pos}\) fibroblasts) in breast cancer TME, which determine therapeutic response in estrogen receptor (ER) positive breast cancer. We hypothesized that the same fibroblast subtypes would also influence ECM composition and alter the metastatic potential of breast cancer cells. Here, we present the development of a novel fibroblast driven orthotopic model of ER+ breast cancer metastasis, which we combined with an innovative proteomics approach to precisely quantify extracellular matrix proteins.

**Results:** 1. **CDCP1\(^{pos}\) fibroblasts promote increased breast cancer cell mobility, invasion and metastasis compared to CD146\(^{pos}\) fibroblasts.** We demonstrate that CDCP1\(^{pos}\) fibroblasts significantly increase the invasion potential of breast cancer cells, when compared to CD146\(^{pos}\) fibroblasts. Orthotopic co-implantation of ER+ tumor cells with CD146\(^{pos}\) fibroblasts into the mammary fat pad of mice more frequently drives distant organ metastases to lung and brain when compared with tumors implanted with CD146\(^{pos}\) fibroblasts. 2. **Proteomic analysis of ER+ tumors influenced by CDCP1\(^{pos}\) fibroblasts revealed known and novel drivers of breast cancer metastasis.** Breast cancer cells mixed with CD146\(^{pos}\) fibroblasts produce a non-uniform collagen orientation to the tumor border. Our novel proteomic analysis of TME specific proteins revealed that tumors influenced by CDCP1\(^{pos}\) fibroblasts have high expression of many ECM proteins linked to increased risk of breast cancer metastasis, including TNC, FN1, COL5A3, and FBN1 among others. Derived proteomic TME signature exactly predicted lymph node involvement in patients who presented with early stage (T0 and T1) tumors in a cohort of 1,009 breast cancer patients from Cancer Genome Atlas Database. 3. **Inhibiting fibroblast production of Tenascin C (TNC) results in decreased breast cancer cell invasion.** Our *in vitro* mixed co-culture models, which contain ER+ breast cancer cells with both fibroblast subtypes, demonstrate that only CDCP1\(^{pos}\) fibroblasts produce TNC. Furthermore, in spheroid assays with CDCP1\(^{pos}\) fibroblasts and breast cancer tumor cells, invasion is inhibited by TNC knockdown. The invasion phenotype can be rescued by addition of EGF, which suggests TNC promotes invasion via EGFR signaling.

**Conclusion:** Metastatic spread of cancer cells relies heavily on TME alterations and makeup of the extracellular matrix. Our data suggest that fibroblast composition directly influences ECM properties and metastatic potential in breast cancer. Taken together, we believe that a better understanding of ECM composition will lead to a more personalized approach to breast cancer treatment.
Circulating CAF/cancer stem cell co-clusters bolster breast cancer metastasis

Utsav Sharma¹, Philip Miller¹, Kelsie Medina Saenz¹, Manuel Picon-Ruiz¹, Cynthia Morata-Tarifa¹, Angela Spartz², Benjamin Troness², Deanna N Park³, Tiffany N Seagroves³, Joyce M Slingerland¹, Marc E Lippman¹ and Dorraya El-Ashry². ¹University of Miami, Miller School of Medicine, Miami, FL; ²University of Minnesota, Minneapolis, MN and ³The University of Tennessee Health Science Center, Memphis, TN.

Background: Metastatic disease is the primary cause of breast cancer (BC) mortality. Cancer associated fibroblasts (CAFs) are the majority of stroma in BC and critical players in BC malignancy. For example, CAFs are the main source of SDF-1, a prominent chemokine in the tumor microenvironment (TME) that also imparts stem cell-like characteristics to BC cells. Metastasis occurs due to the transport of circulating tumor cells (CTC) and clusters of CTCs through the vasculature. Stem-like CTCs and clusters have a greater propensity to establish metastasis. We recently identified circulating CAFs (cCAFs) in blood from patients with BC and in spontaneous, syngeneic, and xenograft mouse models of BC. cCAFs not only circulate individually, but are also found in clusters with CTCs. In this study, we examine the role of CAFs in promoting egress of stem-like CTCs (cCSCs), determine the capacity of stem-like CTCs to cluster with CAFs, and evaluate the involvement of CTC/cCAF clustering in augmenting BC metastasis.

Methods: Our model employs NSG mice with orthotopic xenograft implantation of BC cells, primary CAF cell lines, or co-implantation of BC and CAF cell lines. We used two different BC cell lines: the non-metastatic BC cell line, MCF-7, and the highly metastatic primary BC cell line, DT28. We also employed the MMTV-PyMT spontaneous model of BC metastasis, and we used BALB/c mice injected with syngeneic 4T1 or 67nR cells to evaluate cCAFs, CTCs, and cluster egress in preclinical models. Mice were sacrificed at specific time points, and cardiac blood was collected. Blood was filtered using the faCTChecker microfluidic filtration instrument (Circulogix). Filters were stained for IF and cCAFs, CTCs, cCSCs, and clusters were enumerated. Tumors from CAF co-injected mice were evaluated for their stem cell-like phenotype and re-implanted in mice to evaluate tumorigenicity and metastasis.

Results: In spontaneous, syngeneic, and orthotopic xenograft models of BC, cCAFs, CTCs, and cCAF/CTCs co-clusters appear early in tumor development. cCAF/CTC clusters increase in correlation with tumor burden and metastasis. Co-inoculation of CAFs with BC cells resulted in a significant increase in tumor progression, metastasis, and in a substantially higher number of both individual cells and clusters in circulation. Dissociated tumor cells from CAF co-injected tumors had a higher proportion of CD44+ stem cell-like cells (CSCs), enhanced ALDH-1 expression, and enhanced mammosphere formation. CD44+ CSCs, individually and in clusters, are found early on in the circulation of mice injected with dissociated tumor cells from CAF co-injected tumors. Upon re-implantation of CAF co-injected dissociated tumor cells without CAFs, dissociated tumor cells showed enhanced tumorigenicity and malignancy.

Conclusion: CAFs are highly motile and cCAFs precede CTCs into circulation and can do so independently of tumor cells. CAFs sustain egress of tumor cells by augmenting malignancy and stemness of BC cells. cCAF clusters with the highly metastatic stem cell-like subset of CTCs bolster metastatic colonization. Targeting primary CAF function and/or cCAF/cCSC co-clusters may provide novel avenues to abrogate BC metastasis.
Platelet derived growth factor receptor-β signaling: A novel therapeutic target for breast cancer associated brain metastasis

Gina M Sizemore, Anisha M Hammer, Katie A Thies, Blake Eason Hildreth, Luke O Russell, Steven T Sizemore, Anthony J Trimboli, Raleigh D Kladney, Sarah A Steck, Manjusri Das, Chelsea M Bolyard, Robert Pilarski, Lynn Schoenfield, Jose Otero, Arnab Chakravarti, Matthew Ringel, Balveen Kaur, Gustavo Leone and Michael C Ostrowski. 1The Ohio State University, Columbus, OH; 2Medical University of South Carolina, Charleston, SC and 3The University of Texas, Houston, TX.

PDGFRβ is a receptor tyrosine kinase found in cells of mesenchymal origin such as fibroblasts and pericytes. Activation of this receptor is dependent on paracrine ligand induction, and its preferred ligand, PDGFB, is released by neighboring epithelial and endothelial cells. While expression of both PDGFRβ and PDGFB has been noted in patient breast tumors for decades, how PDGFB-to-PDGFRβ tumor-stromal signaling mediates breast cancer initiation, progression, and metastasis remains unclear. To test this important research question, we developed a mouse model of mesenchymal-specific PDGFRβ hyper-activation.

PDGFRβ mutant mammary glands exhibit increased tertiary side-branching and epithelial proliferation confirming a stromal-specific PDGFRβ effect on neighboring epithelium during normal development. To test the effect of hyper-active mesenchymal PDGFRβ on disease progression, experimental tail vein metastasis assays were performed where we observed prominent brain metastases in 50% of the PDGFRβ mutant mice (n=5/10) with no brain lesions seen in controls (n=0/19). There was no difference in the incidence of lung or liver metastases in the mutant mice suggesting a pro-metastatic function for PDGFRβ in the brain metastatic niche. To rule out dysfunction of the blood brain barrier contributing to the observed metastatic spread, we then intracranially injected mammary tumor cells, and as expected based on our metastasis assay, found that larger tumors formed in the brains of PDGFRβ mutant mice versus controls. To our knowledge, these combined findings are the first example where genetic manipulation of the stroma increases breast cancer associated brain metastases (BCBM). Given that these pre-clinical data suggest that primary breast tumors expressing high PDGFB could preferentially metastasize to the brain, we analyzed PDGFB protein expression in a tissue microarray comprised of HER2-positive and triple negative breast cancer (TNBC) primary tumors (total n=425). While high PDGFB did not correlate with site-independent metastatic recurrence, it was prognostic of brain metastasis, mirroring our mouse data. Evaluation of PDGFB in a small cohort of matched primary breast tumors with associated brain (n=5) and lung metastases (n=2) revealed intense PDGFB staining in 100% of the brain metastases, but only 50% of the lung metastases. These findings further suggest that high primary tumor PDGFB expression defines a subset of breast cancer patients predisposed to brain metastases and that these patients may benefit from therapeutic inhibition of PDGFRβ signaling. To test this pre-clinically, we treated mice harboring intracranial tumors with the PDGFR specific inhibitor crenolanib. Excitingly, crenolanib treatment significantly inhibited the brain tumor burden in these mice. Combined, our findings to date (1) advocate that primary tumor expression of PDGFB is a novel prognostic biomarker for the development of BCBM and (2) support clinical trial evaluation of PDGFR inhibitors for the prevention and treatment of BCBM. Ongoing studies are evaluating how the PDGFRβ-expressing mesenchymal cells within the brain promote a pro-metastatic niche.
Integrative molecular profiling of breast cancer brain metastasis and patient-derived xenograft organoids from resected breast cancer brain metastases to interrogate and prioritize therapeutic personalized strategies

Aki Morikawa¹, Dan R Robinson¹, Matthew Soellner¹, Yi-Mi Wu¹, Robert Lonigro¹, Rabia Gilani¹, Xu Cheng¹, Eric Lachacz¹, Dafydd Thomas¹, Kait McMurray¹, Jeffrey Smerage¹, Norah L Henry², Jason Heth¹, Arul Chinnaiyan¹, Daniel F Hayes¹ and Sofia Merajver¹.
¹University of Michigan, Ann Arbor, MI and ²University of Utah, Salt Lake City, UT.

Background: Breast cancer brain metastasis (BM) is an area of unmet need in metastatic breast cancer patients. Novel therapeutic interventions to help prevent and treat BM are warranted. We conducted integrative molecular profiling of BM and matched primary tumors (PT) using next-generation DNA and RNA sequencing to examine the molecular landscape. In addition, we established patient-derived xenograft/organoid (PDX/PDO) to examine drug sensitivity according to the molecular and clinical features of the BM.

Methods: Archived, formalin fixed paraffin-embedded BM was collected retrospectively. BM were also collected prospectively at the time of clinically indicated surgical resection through the central nervous system tissue banking and the Michigan Oncology Sequencing Center (MI-ONCOSEQ) protocols. Matched archived PT tissues were collected when available. Integrative next-generation sequencing was conducted using the MI-ONCOSEQ platform. The prospectively collected BM were further used to establish PDXs/ PDOs. Successfully established PDXs/PDOs were used for ex vivo drug testing via MiDrugScreen, a novel drug sensitivity testing platform, where testing was performed in a dose-response format with drug selection prioritized by clinical scenario and molecular alterations if known a priori.

Results: 12 matched BM-PT pairs were analyzed: 6 triple negative, 5 HER2 positive, and 1 ER positive HER2 negative. All except one (11/12) had TP53 mutations. When present, TP53 mutations in BM were also found in PT (except for 1 unknown case in PT due to low coverage). ER+HER2- was the only one without TP53 mutation but had hyper-mutation (APOBEC signature). Driver mutations and unique copy number alterations (CDKN2A loss in 1/12, mutations in PIK3CA in 1/12 and ESR1 in 1/12, CCNE1 amplification in 1/12) were noted in BMs. In 75% of cases, mutational burden was higher in BM vs. PT. 2 PDX/PDO were available for drug testing. PDO-BC9 was noted to have RB1 (splice acceptor) and LOH. As predicted by this alteration, PDO-BC9 was insensitive to CDK4/6 inhibitors (palbociclib, abemaciclib) tested on MiDrugScreen panel. PDX-BC4 was established from PIK3CA and ESR1 mutated BM from an ER+HER2- patient who had previously progressed on endocrine therapy with a CDK4/6 inhibitor. As predicted, the PDX-BC4 was resistant to CDK4/6 inhibitor but interestingly sensitive to PIK3CA, ERK, and MEK inhibitors.

Conclusions: TP53 mutation was highly prevalent and may be a biomarker for increased risk of BM. Further study is warranted to see if specific TP53 mutations are associated with a risk of BM development and can be used in risk stratification for BM specific intervention. Unique molecular alterations in BM compared to matched PT may have a therapeutic implication as a target or resistance biomarker. Conducting drug testing in addition to molecular profiling has the strong potential of being informative in tailoring or prioritizing therapeutic agents in the era of precision medicine. Additional BM PDXs/PDOs from breast and other solid tumors are being examined using this novel therapeutic tailoring approach with the combination of MIIONCOSEQ and MiDrugScreen.
The NEO-LET-EXE-trial: An intra-patient cross-over trial to explore the "lack of cross-resistance" between steroidal and non-steroidal aromatase inhibitors

Nazli Bahrami1, Torill Sauer1,2, Marie Loeng1, Berit Gravdehaug1, Siri S Engebretsen1, Belal Aljabri1, Vahid Bemanian1, Jonas C Lindstrøm2,3, Torben Lüders1,2, Vessela N Kristensen1,2 and Jürgen Geisler1,2. 1Akershus University Hospital, Lørenskog, Norway; 2Institute of Clinical Medicine, University of Oslo, Oslo, Norway and 3Health Services Research Unit, Akershus University Hospital, Lørenskog, Norway.

Background. The aromatase inhibitor letrozole and the aromatase inactivator exemestane currently belong to the most widely used antihormonal drugs for breast cancer worldwide. Both compounds are strongly suppressing estradiol levels in postmenopausal patients with breast cancer. However, in the metastatic setting, these drugs may be used after another, causing new responses in selected patients following switching to the alternative drug after progressing on the first choice. This well-known “lack of cross resistance” has been recognized for some time and is documented by several trials. However, the precise explanation for this clinical observation is still unknown. The solution may potentially lead us to a novel strategy to treat hormone-sensitive breast cancer.

Trial design. NEO-LET-EXE is a neoadjuvant, randomized, open-label, intra-patient cross-over trial.

Eligibility criteria. Postmenopausal patients suffering from estrogen receptor (ER) positive (>50%), HER-2 negative, locally advanced breast cancer, suitable for neoadjuvant/presurgical antihormonal therapy, may be enrolled. Age: 18+ (no upper limit).

Specific aims. To explain the phenomenon of a lack of cross-resistance between steroidal and non-steroidal aromatase inhibitors in vivo. Sequential tumor biopsies and blood samples, obtained at baseline and following 2 months of therapy with each drug given in sequence, will be used to perform a comprehensive exploration of the consequences of each drug therapy. The influence on plasma and tissue steroids (estrogens, androgens, etc.) will be compared. In addition, whole genome sequencing, whole exome sequencing, epigenetics, proteomics and plasma analysis (cytokines, tumor DNA fragments, etc.) will be performed.

Statistical methods. Data will be analyzed using mixed effects models.

Present accrual and target accrual. 49 out of planned 100 patients have been enrolled so far. The last patient is expected to enter the trial in Q4 2019.
An open-label, randomized, multi-center phase 2 study evaluating the activity of lasofoxifene relative to fulvestrant for the treatment of postmenopausal women with locally advanced or metastatic ER+/HER2 - breast cancer (MBC) with an ESR1 mutation

Paul V Plourde¹, Lee S Schwartzberg², Geoffrey L Greene³, David J Portman¹, Barry S Komm¹, Simon N Jenkins¹, Ping-Yu Liu⁴, Miriam D Portman¹ and Matthew P Goetz⁵. ¹Sermonix Pharmaceuticals, Columbus, OH; ²West Cancer Center, Memphis, TN; ³U. of Chicago, Chicago, IL; ⁴Fred Hutchinson Cancer Research Center, Seattle, WA and ⁵Mayo Clinic, Rochester, MN.

Endocrine based therapy is the standard treatment for estrogen receptor positive (ER+) MBC. Agents targeting the ER pathway including aromatase inhibitors (AIs), fulvestrant and tamoxifen along with CDK 4/6 inhibitors are considered standard for first and 2nd line treatment. However, endocrine resistance develops in nearly all patients and the optimal systemic therapy after progression on a CDK 4/6 inhibitor is unknown.

Lasofoxifene is a third generation SERM previously investigated for the treatment of osteoporosis and vulvo-vaginal atrophy (VVA). In a large phase 3 trial evaluating the efficacy of lasofoxifene for the postmenopausal treatment of osteoporosis, lasofoxifene significantly reduced the incidence of ER+ breast cancer. Further unpublished preclinical data have demonstrated significant in vitro and in vivo efficacy in non-clinical breast cancer models including models with and without ESR1 mutants. Moreover, lasofoxifene significantly reduced metastases in ESR1 mutated models. These non-clinical and clinical data provide a strong rationale to pursue a phase 2 clinical trial in women with ER+, ESR1 mutated MBC.

This open-label, multi-center study will compare the efficacy and tolerability of lasofoxifene (5 mg orally daily) to fulvestrant (IM 500 mg D1,15,29 and then q30 D) in a 1:1 randomization. Inclusion criteria include postmenopausal women with ER+ advanced breast cancer; progression on a non-steroidal AI in combination with a CDK 4/6 inhibitor; and a known ESR1 mutation. Approximately 90 patients with measurable or evaluable disease (i.e. bone only) will be recruited to have at least 40 patients per treatment arm. The primary endpoint will be progression free survival (PFS) with secondary endpoints of objective response rate (ORR), clinical benefit rate (CBR), duration of response (DoR) and time to response (TTR). It is assumed that lasofoxifene will double the median PFS compared to fulvestrant in this ESR1 mutation patient population for a hazard ratio 0.5 and a power of 89% to reach a 1-sided p of <0.05.

The study will commence in 4Q2018 and will complete recruitment in 1 year. It is anticipated that 25-30 centers in the US will be participating.
The WinPro study: A window of opportunity study of endocrine therapy with and without prometrium in postmenopausal women with early stage hormone receptor-positive breast cancer

Emma Carson1,2, Davendra Segara2, Andrew Parker2, Sandra O'Toole1, Alan Coates3, Bruce Mann4, Geoffrey Lindeman5, Wayne Tilley6 and Elgene Lim1,2. 1Garvan Research Institute, Sydney, NSW, Australia; 2St Vincent’s Hospital, Sydney, NSW, Australia; 3University of Sydney, Sydney, NSW, Australia; 4Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia; 5Walter+Eliza Hall Institute of Medical Research, Melbourne, Victoria, Australia and 6Dame Roma Mitchell Cancer Research Laboratory, Adelaide, South Australia, Australia.

Background
There is bidirectional interplay between PR and ER in human breast cancers (Lim et al, Endo Rel Can 2016). There is evidence for a reprogramming of ER chromatin binding sites with 470 genes differentially regulated by dual treatment with estrogen plus progestogen compared to estrogen alone in breast cancer cell lines (Mohammed et al, Nature 2015). Functionally, there was an additive anti-cancer effect with the addition of natural progesterone to endocrine therapy in preclinical breast cancer models.

Trial Design
This is a phase II multi-site, randomised, open-label, three-arm, study in 200 postmenopausal women with early-stage ER+, PR+, HER2-negative breast cancer. Eligible patients will be randomised 1:1:1 to receive 14 days of intervention with either letrozole 2.5mg PO daily (arm 1), letrozole 2.5mg + prometrium 300mg PO daily (arm 2) or tamoxifen 20mg + prometrium 300mg PO daily (arm 3), between diagnosis of breast cancer and definite surgery.

Australian Clinical Trials Registry: ACTRN1261800092813

Eligibility Criteria
Inclusion Criteria
a) Histologically confirmed ER+ and PR+ breast cancers (≥10% positive staining cells)
b) HER2/CEP17 ratio of <2 and mean HER2 copy number <6 (ASCO CAP 2013 guidelines)
c) Tumour size ≥1cm on ultrasound and/or mammogram
d) Aged ≥18 years

Exclusion Criteria
a) Currently on hormone therapies (HRT and OCP)
b) Locally advanced/inoperable and inflammatory breast cancer
c) Clinical evidence of metastatic disease
d) Received other preoperative systemic therapies
e) Nut allergy (prometrium contains peanut oil)
f) Prior history of uterine cancer, deep vein thrombosis, pulmonary embolism or clotting disorder
g) Women who are pregnant/breast feeding

Specific Aims
a) Primary Endpoint
The geometric mean suppression of the centrally assessed proliferation marker Ki67, after two weeks of intervention, compared with baseline. This will be obtained by comparing the mean difference in Ki67 staining between pre and post-treated samples in each intervention arm.

b) Secondary Endpoint
Safety and tolerability of combination therapy (NCI-CTCAE v4.0)
c) Translational Endpoints
1. Define a gene set as a predictive biomarker for a reduction in Ki67
2. Evaluate changes in the apoptotic markers Bcl-2 and Caspase 3 in the tumors following intervention
3. Evaluate changes in ER, PR, AR, FoxA1, Cyclin D1 protein and mRNA expression in the tumors following intervention

Statistical Methods
The IMPACT study reported a geometric mean reduction in Ki67 after 2 weeks of preoperative tamoxifen of 59.5% and anastrazole of 76% (Dowsett et al, JNCI 2007). This allows estimation of power to detect differences between Arm 1 and either
Arm 2 or Arm 3 with a p-value of 0.025. For the third possible comparison of Arm 2 vs Arm 3, there is no prior evidence, therefore this as a purely exploratory comparison. With a total trial recruitment of 200 and allowing 4% dropouts, this would give 80% power to detect an improvement in Ki67 suppression from 76% in the letrozole alone control arm to 92% in either experimental arm.

Accrual
Present: 5 (1 site open)
Target: 200 (8 sites total)

Elgene Lim, MBBS, FRACP, PhD. e.lim@garvan.com.au
Phase 1 study of D-0502, an orally bioavailable SERD with optimized pharmacological and PK/PD property for ER-positive breast cancer

Ling Zhang¹, David Dai¹, Zhe Shi¹, Jack Jiang¹ and Yaolin Wang¹. ¹InventisBio Inc., Shanghai, China.

**Background:** Endocrine therapy such as selective estrogen receptor degrader (SERD) fulvestrant has been used effectively to extend the life of HR⁺ (ER⁺ and PR⁺) and HER2⁻ breast cancer patient, either alone or in combination with CDK4/6 inhibitors such as palbociclib or abemaciclib. D-0502 is an orally bioavailable SERD with potent activity in various HR⁺ and HER2⁻ breast cancer cell lines and xenograft models. Its combination with palbociclib in both MCF-7 xenograft model and ESR-1 mutated (Y537S) patient derived breast cancer xenograft models resulted in further tumor growth inhibition or regression. Drug metabolism and pharmacokinetic studies both in vitro and in vivo demonstrated that D-0502 exhibits favorable PK profiles suitable for clinical development.

**Trial Design:** D-0502 is currently being evaluated in a phase 1 trial of women with advanced or metastatic HR⁺, HER2⁻ breast cancer (MBC) (NCT03471663). This is a multicenter, open-label phase I study of D-0502 single agent and D-0502 in combination with standard dose of palbociclib. The primary objective is to characterize the safety and tolerability of D-0502 and D-0502 in combination with palbociclib, to identify an MTD and/or RP2D. The secondary objective is to evaluate the PK properties and the preliminary anti-tumor activities. Patients will receive D-0502 orally every day and treatment will be administered as 28-day cycles. The study has two parts: Dose Escalation (phase 1a) and Dose Expansion and Combination (phase 1b). In phase 1a, patients will be enrolled using a conventional dose-escalation algorithm (3+3 subjects per dose level) with 4 sequential dose cohorts to identify the MTD and RDE (recommended dose for expansion) in phase 1b which will be at or below MTD. In phase 1b, there will be 2 cohorts, one is D-0502 single agent administered at RDE and the other is D-0502 in combination with standard dose of palbociclib, each with approximately 12 patients.

**Key Eligibility Criteria:** Eligible patients included women with confirmed HR⁺, HER2⁻ MBC who have previously received no more than 2 prior chemotherapies for MBC; ECOG 0-1; evaluable (phase 1a) or measurable (phase 1b) disease (RECIST v1.1); premenopausal or postmenopausal status; adequate hematologic, hepatic and renal functions.

**Current Status and Contact Information:** At the time of abstract submission, the first cohort of 50 mg patients have started the study treatment. For inquiry of the study, please contact ling.zhang@inventisbio.com.
Endocrine treatment alone as primary treatment for elderly patients with estrogen receptor positive good prognosis operable breast cancer: A single arm phase II, single institution study

Rebecca Aft¹, Matthew Cherian¹, Ashley Frith¹, Rama Suresh¹, Katherine Glover-Collins¹, Mike Naughton¹, Cynthia Moon¹, Leah Conant¹ and Cynthia Ma¹. ¹Washington University School of Medicine, St. Louis, MO.

**Background:** It is estimated that approximately 46,000 women age >75 are diagnosed annually with breast cancer. Due to competing co-morbidities, there is wide variation in treatment recommendations which can lead to over- or under-treatment. Though surgery for breast cancer is considered low-morbidity, many elderly women given a choice, choose not to have surgery. Previous randomized trials comparing surgery with tamoxifen versus endocrine therapy alone in women age >70 unselected for ER status demonstrated similar overall survival with poorer local control in the latter group. A new standard of care needs to be defined for elderly women with good prognosis ER+ tumors, since these women may benefit from endocrine therapy alone to treat their cancer without compromising local and distant control.

**Hypothesis:** We hypothesize that endocrine therapy alone provides adequate local and systemic control of breast cancer in a subpopulation of women age 70 or older with ER+ breast cancer and good prognostic characteristics.

**Primary Objective**
To correlate response to neoadjuvant endocrine treatment at 6 months with Oncotype DX Recurrence Score (RS) in women with early-stage ER+ breast cancer who are age >70.

**Secondary Objective**
1. To determine the breast cancer-specific survival of women with early-stage ER+ breast cancer, age >70, treated with endocrine therapy alone.
2. To determine the rate of overall survival of women with early-stage ER+ breast cancer, age >70 treated with endocrine therapy alone.

**Study Design:** This is a prospective single arm phase II study. Patients with clinical stage I/II ER+ breast cancer, grade 1-2, Ki67<30 or RS <18 (performed on the diagnostic core biopsy) continue to be enrolled and followed for time to progression. A Kaplan-Meier model will be used to estimate the 5-year local progression rate. If the true 5-year progression rate is 10%, then 50 patients will provide power = .90 at a one-sided .05 significance level to demonstrate that the rate is less than 25.5%. Exploratory objectives include: evaluation of the molecular characteristics of breast cancers of responders versus non-responders, determine compliance with medications, evaluate cost-effectiveness, and quality of life.

**Results:** Between February 2017 and April 2018, 11 patients were enrolled into the study. Two patients could not tolerate endocrine therapy and received standard of care treatment. For the 9 patients on study, average tumor size was 1.7cm, average Ki67 was 15%, average RS was 14. All of the patients received an aromatase inhibitor. At 6 months, 71% of the patients had a partial response, 28% had stable disease. None of the patients developed progressive disease.

**Conclusion:** A new standard of care needs to be defined for women age >70 with good prognosis ER+ tumors, since these women may benefit from endocrine therapy alone to treat their cancer without compromising local and distant control. We continue to enroll patients to determine the optimal tumor markers for identifying women who can be treated with PET only to control their cancer.
POSITIVE: A study evaluating Pregnancy, disease outcome and safety of interrupting endocrine therapy for premenopausal women with endocrine responsive breast cancer who desire pregnancy (IBCSG 48-14/BIG 8-13)

Olivia Pagani, Ann H Partridge, Fedro Peccatori, Hatem A Azim, Marco Colleoni, Cristina Saura, Judith R Kroep, Ellen Warner, Andrea Gombos, Anna B Sætersdal, Monica Ruggeri, Richard D Gelber and Zhuoxin Sun. 1Oncology Institute of Southern Switzerland, Bern, Ticino, Switzerland; 2Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; 3European Institute of Oncology (IEO), Milan, Italy; 4American University of Beirut (AUB), Beirut, Lebanon; 5Vall d’Hebron University Hospital, Barcelona, Spain; 6Leiden University Medical Center, Leiden, Netherlands; 7Sunnybrook Health Sciences Centre, Toronto, Canada; 8Institut Jules Bordet, Brussels, Belgium; 9Oslo University Hospital, Oslo, Norway; 10International Breast Cancer Study Group, Bern, Switzerland and 11International Breast Cancer Study Group Statistical Center and Frontier Science and Technology Research Foundation, Boston, MA.

Background
Young patients with breast cancer (BC) are often diagnosed with the disease before completing their families. The best available retrospective evidence suggests that pregnancy after BC does not negatively impact disease outcomes in patients with endocrine responsive BC and is safe for the offspring. However, given the possibility of extended adjuvant endocrine therapy (ET) (5-10 years), it is not feasible for many of these women to delay pregnancy until completion of therapy and thus there is a need to study the safety of interrupting ET to allow pregnancy. To date, no prospective study has been conducted in BC survivors attempting future pregnancy.

Trial Design
Young patients with endocrine responsive early BC who desire pregnancy will interrupt ET for up to 2 yrs to attempt pregnancy. As resumption of menses and conception depends on many factors (e.g. patient's age and adjuvant treatment received), the 2-yr interruption period is approximate, intended to include treatment wash-out (3 mos), conception (~3-6 mos), delivery (~9 mos), and breast feeding (~6 mos). Patients will be strongly advised to resume ET as soon as pregnancy attempts/deliveries are concluded, and to complete the planned 5-10 yrs of ET.

Major Eligibility Criteria
- Histologically-proven stage I-III endocrine-responsive BC.
- Patient's wish to become pregnant.
- Age ≥ 18 and ≤ 42 years at enrollment.
- Adjuvant ET (selective estrogen receptor modulator [SERM] alone, GnRH analogue plus SERM or aromatase inhibitor) for ≥18 months but ≤30 months, stopped within 1 month prior to enrollment.
- Premenopausal status at BC diagnosis.

Specific Aim
To assess the risk of BC relapse associated with the interruption of ET to permit pregnancy, and to evaluate pregnancy success rate and offspring outcome.

Statistical Methods
With 500 pts enrolled and followed for a median of 3 years, the statistical design is based on the 95% CI for the 3-year BC recurrence rate. Interim monitoring assumes a 2% BC recurrence risk/yr with continuous ET and a recommendation to stop the study early if the BC risk exceeds 4%/yr with ET interruption.

Translational Research will investigate various ovarian function and uterine parameters and circulating tumour DNA. Fresh frozen paraffin embedded tissue of the primary tumour will be collected to evaluate parameters related to the biology of BC in young women. All material will be banked centrally.

Psycho-oncological Companion Study (POCS) will evaluate fertility concerns, psychological well-being and decisional conflict. It is mandatory in North America and open to interested centers elsewhere.

Accrual: Target: 500; Actual: 262 (30 June 2018)
Psycho-oncological Companion Study Accrual: Target: 200; Actual: 138 (30 June 2018)
Background:
Published preclinical findings provided new insights into the functional ‘cross-talk’ between the oestrogen receptor (ER) and the progesterone receptor (PR) in breast cancer (BC) (Mohammed et al., Nature, 2015). Addition of a PR agonist to anti-oestrogens directly modifies ERα chromatin binding and the transcriptional response in breast cancer cells, and is anti-proliferative in vitro and in vivo.
Megestrol Acetate (MA), an off-patent semi-synthetic derivative of progesterone, has been licensed for many years as treatment for ER+ metastatic BC. There is also good evidence for the effectiveness of MA as a supportive therapy to ameliorate endocrine therapy-related hot flushes.

Trial design:
PIONEER is a three-arm, open label, multi-centre randomized phase II pre-surgical window trial evaluating effects of 15 days of preoperative therapy with Letrozole (LET), or LET plus MA 40mg, or LET plus MA 160mg in postmenopausal women with ER+ HER2- invasive primary BC.

Eligibility criteria:
Inclusion Criteria
Postmenopausal women with histologically confirmed invasive BC, ≥T1c, clinical NX or N0-N3, ER+ (Allred≥3), and HER2- 2 groups of patients are potentially eligible:
Cohort A: Patients whose cancers have been deemed to be operable by the Multi-Disciplinary Team (MDT) with surgery planned for the next 2-6 weeks
Cohort B: Patients with early or locoregionally advanced BC planned for primary endocrine therapy either in lieu of surgery or as neoadjuvant therapy before surgery
  ECOG performance status of 0-2
  Adequate Liver, Renal, Bone marrow function
Exclusion Criteria
  Hormone replacement therapy in the last 6 months
  Treatment with tamoxifen or an aromatase inhibitor (AI) in the last 6 months
  A progestogen-containing intrauterine system in situ, unless removed prior to randomisation
  Metastatic disease on presentation
  Recurrent BC (patients with a new primary invasive BC are eligible)

Specific aims:
The primary endpoint is % change in proliferation between baseline and day 15 tumor biopsies, measured by Ki67 IHC assessment. Secondary endpoints include: expression of Aurora Kinase A, Caspase 3 and AR/PR/EMT markers by IHC; and safety endpoints. Exploratory endpoints: transcription factor mapping (ChIP-seq) and identification of differential ERα-associated proteins (RIME) on paired fresh-frozen tumor samples.
PIONEER will help determine whether there is value in conducting a Phase III adjuvant study to investigate the longer term benefit of combining an AI with MA, and if so, at what dose (40mg vs. 160mg).

Statistical methods:
Patients are randomized in a 1:1.5:1.5 ratio into arms A:B:C. Based on results from previous clinical trials, a mean 66% reduction in Ki67 is anticipated for LET alone (arm A), and a 77.5% reduction for the combination arms B and C, based on preclinical data.
Present and target accrual:
Patients are being recruited in Cambridge, Cornwall, Belfast & London with 6 other UK sites due to open q3/4 2018. At the time of submission, 29 patients had been recruited. A recruitment total of 189 patients is required.
Phase I trial of bicalutamide and ribociclib in androgen receptor-positive triple negative breast cancer

Marina Sharifi¹, Kari B Wisinski¹, Mark E Burkard¹, Amye J Tevaarwerk¹, Deimante Tamkus², Nancy Chan³, Cristina Truica⁴, Oana Danciu⁵, Kent Hoskins⁶ and Ruth M O'Regan¹. ¹University of Wisconsin, Madison; ²Michigan State University, East Lansing; ³Rutgers Cancer Institute of New Jersey, New Brunswick; ⁴Pennsylvania State Hershey Cancer Institute, Hershey and ⁵University of Illinois at Chicago, Chicago.

Background: To date, the use of anti-androgens in the subset of triple negative breast cancers (TNBC) that express androgen receptor (AR) has shown modest response rates, indicating anti-androgen-resistance in the majority of these tumors. Based on data that Cyclin D kinase (CDK) inhibitors reverse resistance to anti-androgens in prostate cancer cell lines, we hypothesize that the use of CDK inhibition may enhance the activity of anti-androgens in AR-positive TNBC.

Methods: Key eligibility include: patients with centrally confirmed AR-positive TNBC, defined as AR expression >0%; 0 to 1 line of prior therapy for metastatic disease; and measurable disease. Patients are treated with bicalutamide 150mg orally once daily plus ribociclib at one of 3 dose levels (see table).

Table 1

<table>

</tbody>
</table>

Results: AR expression was positive by trial criteria in 74% of screened patients. Three patients have been accrued at each dose level. Median age is 56 and 6 and 3 patients were treated in first and second-line settings, respectively. Median AR expression was 50% (range 5 to 75%). Toxicity data is available for 6-patients treated on dose levels 1 and 2. No dose-limiting toxicities were noted. As anticipated with ribociclib, the most common toxicity is neutropenia (1 patient grade 4 and 2 patients grade 3). Two patients experienced grade 3 hypertension and 1 experienced grade 3 lymphopenia. Grade 2 or lower toxicities included fatigue, nausea, hyperglycemia and mucositis. One patient experienced grade 1 QT interval prolongation.

Conclusion: The combination of bicalutamide and ribociclib is tolerable without unexpected toxicities. Data on the 3-patients treated at dose level 3 and dose expansion will be included. Phase 2 dosing schedule will be decided based on phase 1 results.
A phase 1, first-in-human, multi-part study of RAD140, an oral nonsteroidal selective androgen receptor modulator, in postmenopausal women with hormone receptor positive breast cancer

Erika Hamilton¹, Neelima Vidula², Cynthia Ma³, Patricia LoRusso⁴, Jamal Saeh⁵, Vienna Reichert⁶, Ziyang Yu⁵, Miriam Annett⁵, Aaron Weitzman⁵, Gary Hattersly⁵, Alison O'Neill⁵ and Amy Weise⁵. ¹Sarah Cannon Research Institute/Tennessee Oncology, Nashville; ²Massachusetts General Hospital, Boston; ³Washington University School of Medicine, Saint Louis; ⁴Yale Cancer Center, Yale University, New Haven; ⁵Radius Health, Inc., Waltham and ⁶Karmanos Cancer Institute/Wayne State University, Detroit.

Background: Hormone receptor-positive (HR+) breast cancer accounts for about 75% of breast cancer cases. Despite initial response to ER-targeted therapies, subsequent tumor progression remains an important clinical problem, highlighting the need for new therapies with activity in endocrine-resistant tumors. The androgen receptor (AR) is expressed in up to 90% of ER+ breast cancers, and until the 1970s, breast cancer was commonly treated with androgens with single-agent response rates ranging from 20% to 25%. However, androgen-based therapy for breast cancer declined due to lack of tissue selectivity, potential for aromatization to estrogen, and the emergence of ER-targeted agents such as tamoxifen.

RAD140 is an oral nonsteroidal selective androgen receptor modulator (SARM) that cannot be converted to estrogen by aromatase. RAD140 has high AR affinity and target selectivity, demonstrating marked tissue-selective AR agonist activity comparable to natural androgens in breast cancer cells, but lacking agonist activity in prostate cancer cells. Preclinical efficacy studies in multiple in vivo and in vitro models of AR+/ER+ breast cancer demonstrate potent anti-tumor activity of RAD140 as a single agent and in combination with a CDK4/6 inhibitor. This first-in-human study will evaluate the safety, tolerability, pharmacokinetics (PK) and clinical activity of RAD140 in patients with HR+ breast cancer.

Trial Design and Specific Aims: This is a Phase I, open-label dose escalation and safety expansion study of RAD140 in postmenopausal patients (pts) with advanced HR+ breast cancer for whom no standard therapy is available. During dose escalation (Part A), pts are assigned sequentially to escalating doses of RAD140 using a standard 3+3 design to establish a maximum tolerated dose (MTD) and/or recommended dose (RD) based on safety, PK and preliminary clinical activity. The Safety Expansion (Part B) will further evaluate the safety, tolerability and clinical activity of the RD.

Eligibility Criteria: Pts must be post-menopausal females ≥18 years old with locally advanced or metastatic ER+/HER2- (Part A) or ER+/AR+/HER2- (Part B) breast cancer and ECOG 0 or 1. Part A pts must not be eligible for standard therapy. Pts in Part B must have had at least 1 line of prior systemic therapy in the metastatic setting and at least 6 months of prior endocrine therapy in the metastatic setting and progressed on the most recent endocrine therapy. Measurable disease by RECIST 1.1 is also required for enrollment in Part B.

Statistical Methods: Descriptive statistics (including mean, standard deviation, median for continuous variables; frequency counts and percentages for categorical variables) will be presented by dose. Plasma or serum PK parameters for RAD140 will be estimated using non-compartmental methods.

Present Accrual and Target Accrual: The study will enroll up to 40 pts, including up to approximately 24 pts enrolled in cohorts of 3 to 6 in Part A, and another 15 pts enrolled in Part B. As of June 2018, 11 pts have enrolled at 5 sites. (NCT03088527)

**Publication Number:** OT1-03-01

Phase 1/1b study of novel oral selective estrogen receptor degrader (SERD) LSZ102 in combination with alpelisib (BYL719) in estrogen receptor-positive (ER+), human epidermal growth factor receptor-2–negative (HER2–) advanced breast cancer (ABC) with progression on endocrine therapy (ET)

Giuseppe Curigliano¹, Sara Cresta², Yoon-Sim Yap³, Dejan Juric⁴, Francois P Duhoux⁵, Catherine Terret⁶, Shunji Takahashi⁷, Rachel M Layman⁸, Nicole Kundamal⁹, Serena Liao¹¹, Adam Crystal¹¹ and Komal Jhaveri¹². ¹University of Milan, Istituto Europeo di Oncologia – IRCCS, Milan, Italy; ²Fondazione IRCCS – Istituto Nazionale dei Tumori, Milan, Italy; ³National Cancer Centre Singapore, Singapore, Singapore; ⁴Massachusetts General Hospital, Boston, MA; ⁵Cliniques Universitaires Saint-Luc, Brussels, Belgium; ⁶Centre Léon Bérard, Lyon, France; ⁷The Cancer Institute Hospital of JFCR, Tokyo, Japan; ⁸The University of Texas MD Anderson Cancer Center, Houston, TX; ⁹Novartis Institutes for Biomedical Research, East Hanover, NJ; ¹⁰Novartis Pharma AG, Basel, Switzerland; ¹¹Novartis Institutes for Biomedical Research, Cambridge, MA and ¹²Memorial Sloan Kettering Cancer Center, New York, NY.

**Background:** Although ET remains the basis of therapy for ER+, HER2– ABC, treatment resistance frequently occurs. Novel strategies to target the receptor and/or alternative pathways to overcome therapeutic resistance are under investigation. LSZ102 is a novel, orally bioavailable, nonsteroidal SERD. Preclinically, LSZ102 inhibits ER gene transcription, induces receptor degradation, blocks ER-dependent cell growth, and has synergistic activity with the phosphoinositide 3-kinase (PI3K)-alpha inhibitor alpelisib (BYL719). The present study is evaluating the safety and tolerability of LSZ102 plus alpelisib in patients with ER+, HER2– ABC with progression on ET.

**Trial Design:** This phase 1/1b, open-label study is enrolling ~18-30 patients (men and women of any menopausal status) in Arm C of the dose-escalation part of the study, which investigates the combination of LSZ102 and alpelisib; additional study arms will investigate LSZ102 as a single agent or in combination with ribociclib. Enrollment in Arm C started after identification of a safe and tolerable single-agent dose for LSZ102. Alpelisib dosing began at 200 mg/day and will not be escalated beyond the maximum tolerated dose (MTD) determined in the alpelisib single-agent arm of study CBYL719X2101 (400 mg/day). Dose escalation of alpelisib in combination with LSZ102 is guided by BLRM and integrates Cycle 1 DLT rates, lower grade and later cycle AE, PK, PD and preliminary activity to identify a recommended dose for expansion (RDE). Patients will receive treatment until disease progression, unacceptable toxicity, or withdrawal of consent. For inclusion in the study, patients must have histologically confirmed ER+, HER2– ABC and disease progression after ET for ABC or recurrence on/within 12 months of completion of adjuvant ET. In the escalation part of the study, patients are eligible regardless of PIK3CA status. Premenopausal women must receive concomitant treatment with a gonadotropin-releasing hormone agonist. Eligible patients must have adequate bone marrow and organ function, Eastern Cooperative Oncology Group performance status of 0 or 1, and have completed and recovered from acute toxicities of radiotherapy and/or prior anticancer therapy. Exclusion criteria include symptomatic central nervous system metastases, clinically significant cardiac disease or impaired cardiac function (including a QT interval corrected for heart rate using Fridericia's formula [QTcF] >460 ms in women or >450 ms in men), uncontrolled diabetes mellitus type II (or type I), and prior treatment with a PI3K inhibitor. The primary objectives are characterization of safety and tolerability for the combination and identification of a recommended dose. Secondary objectives include characterization of pharmacokinetic properties and pharmacodynamic effects. Recruitment for Arm C is ongoing. NCT02734615
CICLADIES: Monitoring of ESR1, PIK3CA and AKT1 ctDNA mutations during real-life follow-up of patients with advanced breast cancer treated with endocrine therapy

Vincent Massard1, Lionel Uwer1, Julia Salleron1, Mathilde Debloc1, Anne Kieffer1, Maria Rios1, Pauline Gilson1, Anne Lesur1, Alexandre Harle1 and Jean Louis Merlin1. 1Institut de Cancérologie de Lorraine, Vandoeuvre les Nancy, France.

Activating ESR1 mutations have recently been reported as a key mechanism leading to Aromatase Inhibitor (AI) resistance. ESR1 mutations occur rarely in primary breast cancers. However, in large retrospective studies, ESR1 mutations occurred in up to 39% of Estrogen-Receptor(ER)-positive metastatic breast cancer resistant to AI. Numerous hotspot mutations have been identified, most of them affecting the ligand-binding domain (LBD) and leading to ligand-independent activation of the ER and to resistance to AI.

Phosphatidylinositol 3-kinase (PI3K)/AKT pathway is involved in key cellular mechanisms and mutations in PIK3CA and AKT1 are frequently reported in breast cancer.

In this study, we propose to use a capture-based Next Generation Sequencing (NGS) assay and to use the barcoding and polishing features in our analysis pipeline. This assay will be able to detect all mutations on AKT1, PIK3CA, ESR1 and other genes on circulating tumor DNA (ctDNA) extracted from blood samples of patients with breast cancer. We consider that this exon-screening strategy is relevant according to the recent knowledge.

We plan to prospectively include women with advanced breast cancer about to begin standard-of-care first line endocrine therapy (ET). Patients will be required to have histologically confirmed ER-positive, HER2-negative breast cancer and documented loco-regionally advanced or metastatic disease, not amenable to surgery or radiation with curative intent. Patients with endocrine sensitive disease (no prior ET or relapse more than 12 months after completing adjuvant ET) as well as patients with endocrine resistant disease (relapse while on adjuvant ET or within 12 months of completing adjuvant ET) will be enrolled.

ET can be prescribed alone or in combination with a targeted therapy. Nevertheless, we will recruit at least 25% of patients with exclusive ET in the endocrine sensitive group.

Peripheral-blood samples, for analysis of ctDNA, will be obtained from participating patients at pre-specified time points: at start of ET to determine the baseline mutational status of ESR1, PIK3CA, AKT1 and other genes included in a panel of genes of interest in solid tumors, and then, at evaluation of response to therapy until disease progression or end of study.

Patients will be followed for 36 months or until disease progression. Determination of progression will be done per local investigator.

The primary objective is to describe the prevalence of activating ESR1 mutations affecting the LBD, using NGS, from the start of ET to progression or end of study. Secondary objectives include to describe the prevalence of ESR1 mutations affecting other domains, the prevalence of ESR1 mutations in patients with and without endocrine resistance at enrolment and the prevalence of PIK3CA and AKT1 mutations, to demonstrate that ESR1, PIK3CA and AKT1 mutations whatever their times of onset are predictors of progression free survival.

As of June 2018, 8 sites were opened to recruitment and 18 pts were included; the target enrollment is 146. The trial is supported by AstraZeneca.
Background: Sulforaphane, a plant secondary metabolite, was first identified as an anti-cancer agent in 1992, although its inherent instability has thus far held back its clinical development. SFX-01 is a proprietary synthetic pharmaceutical development product based upon a stabilised sulforaphane. Preclinical data show sulforaphane and SFX-01 inhibit breast cancer stem cells\(^{1,2}\) and SFX-01 potently suppresses STAT3 in ER+ metastatic breast cancer (mBC) PDX tumours\(^3\). It is therefore hypothesised that SFX-01 could become a potential therapy for reducing resistance to hormone therapy in patients with mBC.

Trial Design: An open label trial with a maximum target of 60 patients with ER+, HER2-negative, mBC who are on a third generation AI, tamoxifen (Tam) or fulvestrant (Fulv) and have evidence of emerging secondary endocrine resistance. Participants remain on AI, Tam or Fulv and take this in combination with 300mg SFX-01 orally, twice-daily, and are scanned every 6 weeks (wks) until disease progression. Patients come off study at disease progression or at the full term of 24wks. Patients who are progression free as they approach 24wks can be enrolled in a compassionate use phase.

Key Eligibility Criteria

- Male or female patients 18yrs or older
- Histological confirmation of ER+ HER2-negative breast cancer
- Clinical or histological confirmation of metastatic or locally advanced disease not amenable to curative surgical resection
- At least 1 site of measurable disease
- Must be on a third generation AI, tamoxifen (Tam) or fulvestrant (Fulv) and have evidence of emerging secondary endocrine resistance as evidenced by either: a) Progressive disease while on adjuvant ET but after the first 2 years, or b) Progressive disease within 12 months of completing adjuvant ET, or c) Progressive disease while on ET, ≥6 months after initiating ET for metastatic breast cancer
- No more than 3 lines of endocrine therapy including the treatment at the time of study entry
- No more than 1 prior line of chemotherapy for metastatic/locally advanced breast cancer

Specific Aims: The primary objectives are to determine the safety & tolerability of SFX-01 in combination with AI, Tam or Fulv and to determine clinical benefit rate (CBR) at 24wks using RECIST v1.1. Time to response, objective response rate, progression free survival interval and the PK of SFX-01, AI, Tam & Fulv will also be assessed.

Statistical Methods: Demographic, baseline characteristics, safety and efficacy data will primarily be summarised descriptively. The sample size of 20 patients in each treatment cohort is such that if the observed CBR on any arm is 15%, it will provide a 90% exact binomial confidence interval (CI) for the true CBR of 4.2% to 34.4%. Duration of response will be compared to duration of response on prior ET.

Accrual: To date, 46 of the maximum target of 60 patients have been enrolled across 10 centres in UK, Belgium, France and Spain. Final study results are expected end of 2018.

**Background**

Mutations in the ligand-binding domain of \( ESR1 \) have been demonstrated to mediate resistance to aromatase inhibitors (AI) and are associated with poor survival. Analyses of circulating tumor DNA (ctDNA) offer a minimally invasive and real-time approach to characterize genomic landscape, clonal evolution, and treatment response. Early detection and intervention with alternate therapy to overcome resistance at minimal disease burden progression could have a larger impact than treating higher burden disease at clinical progression. However, whether treatment decisions made based on the emergence of secondary resistance mutations or mutant allele fraction (MAF) changes in ctDNA can improve clinical outcomes is unknown. Currently, the most effective therapy for patients harboring \( ESR1 \) mutations is unclear; although, pre-clinical and retrospective clinical trial analyses have suggested that some of these mutations may exhibit greater sensitivity to fulvestrant, a selective estrogen receptor down-regulator, compared to AI. This study hypothesizes that real-time monitoring of ctDNA for secondary ESR1 alterations can identify subclinical progression and early intervention with a targeted-agent that has greater efficacy against \( ESR1 \) mutations can improve disease-free survival.

**Trial Design**

This is a randomized, open-label, Phase-2 study for HR-positive MBC patients who are on AI and CDK 4/6 inhibitor as first line therapy. Patients on treatment for at least 12 months without evidence of clinical progression would be screened for \( ESR1 \) mutations using Guardant360 ctDNA assay. Patients with positive \( ESR1 \) mutations would be randomized to change of endocrine therapy to fulvestrant vs. continuing AI.

**Eligibility criteria**

- Histologically confirmed HR-positive (ER and/or PR >10%) and HER2-negative MBC
- On AI with CDK4/6 inhibitor as first line therapy for 12 months without evidence of clinical progression
- Activating \( ESR1 \) mutation identified on ctDNA
- ECOG performance status ≤1
- Normal organ and marrow function

**Specific aims**

- To assess progression-free survival (PFS) with transition to fulvestrant compared with continuing AI therapy in patients with emergence of \( ESR1 \) mutations in plasma
- To assess ctDNA \( ESR1 \) mutant allele fraction and kinetics with transition to fulvestrant compared with AI
- To assess the prevalence of \( ESR1 \) mutations in patients with exposure to endocrine therapy
- To assess overall survival with fulvestrant transition compared with continuing AI therapy in patients with emergence of \( ESR1 \) mutations

**Statistical methods**

To detect a change in median PFS from 5 months (for AI arm) to 9 months (with fulvestrant arm) would require about 124 patients (5% two-sided alpha, 80% power, log rank testing). Interim analysis will be performed when 42 PFS events are observed. Using O'Brien-Fleming stopping boundaries, we will stop for futility if the log rank test p-value > 0.72 and stop for success if it is < 0.004.
A phase IIB pre-surgical trial of oral tamoxifen (TAM) versus transdermal 4-hydroxytamoxifen (4-OHT) in women with DCIS of the breast

Kelly A Benante¹, Yanfei Xu¹, Mary Beth Tull¹, Adrian J Segura¹, Katrina M Alber¹, Kiril Kalinichenko¹, Lifang Hou¹, Borko Jovanovic¹, Marjorie Perloff², Brandy Heckman-Stoddard², Eileen Dimond² and Seema A Khan¹. ¹Northwestern University, Chicago, IL and ²National Institutes of Health, Bethesda, MD.

**Background**

Ductal carcinoma in situ (DCIS) is diagnosed in 60,000 women annually in the US. TAM is proven to reduce risk of local recurrence and new primary breast cancer in women with estrogen receptor (ER) positive DCIS. However, acceptance of TAM has been low, primarily because of toxicity related to systemic exposure. Local delivery to the breast is an attractive alternative since low systemic levels could minimize toxicity. 4-OHT is an active metabolite of TAM. When formulated as a gel and applied to the breast skin, it is well tolerated, and results in 4-OHT breast tissue drug levels comparable oral TAM. In small pilot studies, its anti-proliferative effects on invasive breast tumors and DCIS are also similar to oral TAM [Lee O, et al. PMID 25028506]. The goal of our study is to validate these results in preparation for a Phase III trial of 4-OHT gel in comparison to oral TAM.

**Methods**

We are conducting a randomized, double-blinded, placebo-controlled, Phase IIB pre-surgical trial to demonstrate that daily application of 4-OHT gel will result in a reduction in the Ki-67 labeling index of DCIS lesions that is not inferior to that seen in women receiving daily oral TAM 20 mg daily. Ki-67 of the base-line diagnostic core needle biopsy will be compared to that of the therapeutic surgical excision sample after oral TAM or 4-OHT gel for 8 ± 2 weeks. Secondary endpoints include changes in Oncotype DCIS-Score, IHC markers (CD68, COX2, p16), hormone levels, coagulation markers, drug concentration in the plasma and breast tissue, the fraction of women with no residual DCIS in the surgical sample, and experienced symptoms. 100 women (assuming 20% non-evaluable samples or compliance issues) with DCIS (10% ER-positive) will be enrolled across six institutions into two intervention arms: oral TAM 20 mg daily, placebo gel and 4-OHT gel 4mg daily (2mg/breast), placebo capsule. All participants will be evaluable for toxicity from their first dose. All samples from all participants who receive drug will be evaluated and included in the primary analysis, which will be based on intent to treat principle. To date 15 of 100 participants have been enrolled across six institutions including: Northwestern University in Chicago, IL, St. Elizabeth Healthcare in Edgewood, KY, Duke University Medical Center in Durham, NC, Cleveland Clinic in Cleveland, OH, Memorial Sloan Kettering Cancer Center in New York, NY, and Mayo Clinic in Rochester, MN. Since study open, 69 potential participants have been contacted, 52 did not consent for screening, 17 consented for screening, 2 are pending consent, and 15 have started study intervention. The most common reasons potential participants chose not to consent are wanting to schedule surgery as soon as possible, attitudes toward medical research, and current use of a prohibited concomitant medication such as a potent inhibitor of tamoxifen metabolism or exogenous sex steroid.

**Funding Source:** NCI Contract # HHSN2612201200035I.
A pilot study of the combination of entinostat with capecitabine in metastatic and high risk breast cancer after neoadjuvant therapy

Trish A Millard¹, Nolan A Wages¹, Gina R Petroni¹, Christiana M Brenin¹ and Patrick M Dillon¹. ¹University of Virginia, Charlottesville, VA.

Background:
HDAC inhibitors (HDACi) upregulate thymidine phosphorylase resulting in enhanced conversion of capecitabine to active 5-fluorouracil and in synergistic anti-proliferative effects. HDACi's down regulate thymidine synthase and may prevent resistance to fluoropyrimidines. Entinostat is a well-tolerated class I HDACi in phase III trials for metastatic breast cancer.

Specific Aims:
The primary objective is to determine the maximum tolerated dose combination (MTDC) of entinostat and capecitabine in participants with metastatic breast cancer. It is hypothesized that entinostat and capecitabine is a synergistic, safe, and tolerable combination.
An expansion phase will assess the safety of the MTDC from Part A in participants with high risk breast cancer after neoadjuvant therapy. The expansion phase will generate a preliminary estimate of disease-free survival. Exploratory objectives include estimates of the association of volume of circulating tumor DNA (ctDNA) and circulating tumor cells (CTCs) with the presence of residual disease and if it decreases following treatment with the combination of entinostat and capecitabine.

Trial Design:
The dose escalation phase (Part A) will accrue participants with metastatic breast cancer using an adaptive design to determine the MTDC. The starting doses will be entinostat 3mg po weekly and capecitabine 800mg/m² po bid, 14 days on and 7 days off with 21 day cycles. Patients will be monitored for toxicity and adverse events. The MTDC is defined as the dose combination with DLT rate closest to the target DLT rate of 25%.
The expansion phase (Part B) will accrue breast cancer participants with residual invasive disease after neoadjuvant therapy starting at the MTDC estimated in Part A. The adaptive modeling design will be used in Part B to establish the MTDC in this patient population. Participants will be treated with the MTDC for a total of 8 cycles.
Blood samples will be obtained from all enrolled patients in the expansion phase prior to the start of adjuvant treatment with entinostat and capecitabine so that ctDNA and CTCs can be measured as correlative studies. Measurements will be repeated at the end of the eighth cycle.

Eligibility Criteria:
Part A: Dose Escalation Phase: Stage IV breast cancer patients; Receptor Status: hormone receptor positive or negative, triple negative patients; Age: 18 year and older
Part B: Expansion Phase: Stage I-III high risk breast cancer patients; Completed at least four cycles of neoadjuvant taxane or anthracycline based chemotherapy; Residual invasive disease (ypT1a or greater) or known positive lymph nodes (ypN0(itc) or greater); Receptor Status: hormone receptor positive or negative, triple negative patients; Age: 18 years and older

Statistical Methods:
The trial is designed to determine the MTDC, defined by acceptable toxicity of the combination, for two study populations. A Bayesian adaptive design is being used to guide accrual decisions based on the occurrence of DLTs, and the minimum follow-up period for determination of escalation is 3 weeks.

Accrual:
Maximum target accrual is 55 participants. Accrual is estimated at 1-2 participants per month.

OPTIMA: A prospective randomized trial to validate the clinical utility and cost-effectiveness of gene expression test-directed chemotherapy decisions in high clinical risk early breast cancer

Robert C Stein¹, Luke Hughes-Davies², Andreas Makris³, Iain R Macpherson⁴, Carmel Conifrey⁵, Leila Rooshenas⁵, Sarah E Pinder⁶, Jeremy Thomas⁶, Peter S Hall⁷, David A Cameron⁷, Helena M Earl⁸, Bjørn Naume⁹, Christopher J Poole¹⁰, Daniel W Rea¹¹, Stuart A MacIntosh¹², Victoria Harmer¹³, Adrienne Morgan¹⁴, Claire Hulme¹⁵, Christopher McCabe¹⁶, Nigel Stallard¹⁷, Helen Higgins¹⁷, Jenny L Donovan⁶, John MS Bartlett¹⁸, Andrea Marshall¹⁷ and Janet A Dunn¹⁷. ¹National Institute for Health Research University College London Hospitals Biomedical Research Centre, London, United Kingdom; ²Addenbrooke’s Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; ³Mount Vernon Cancer Centre, Northwood, United Kingdom; ⁴Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom; ⁵University of Bristol, Bristol, United Kingdom; ⁶Kings College London, London, United Kingdom; ⁷Edinburgh Cancer Research Centre, University of Edinburgh, Edinburgh, United Kingdom; ⁸University of Cambridge and NIHR Cambridge Biomedical Research Centre, Cambridge, United Kingdom; ⁹Oslo University Hospital HF, Radiumhospitalet, Postboks 4953 Nydalen, Oslo, Norway; ¹⁰University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; ¹¹Institute of Cancer and Genomic Sciences, University of Birmingham, Birmingham, United Kingdom; ¹²Queen's University Belfast, Belfast, United Kingdom; ¹³Imperial College Healthcare NHS Trust, London, United Kingdom; ¹⁴Independent Cancer Patients’ Voice, London, United Kingdom; ¹⁵Academic Unit of Health Economics, University of Leeds, Leeds, United Kingdom; ¹⁶University of Alberta, Edmonton, AB, Canada; ¹⁷Warwick Medical School, University of Warwick, Coventry, United Kingdom and ¹⁸Ontario Institute for Cancer Research MaRS Centre, Toronto, ON, Canada.

Background: Multi-parameter tumour gene expression assays (MPAs) are widely used to estimate individual patient residual risk and to guide chemotherapy use in hormone-sensitive, HER2-negative early breast cancer. The TAILORx trial supports MPA use in a node-negative population. Evidence for MPA use in node-positive breast cancer is limited. OPTIMA (Optimal Personalised Treatment of early breast cancer usIng Multi-parameter Analysis) (ISRCTN42400492) aims to validate MPAs as predictors of chemotherapy sensitivity in a largely node-positive breast cancer population where prospective RCT (Randomised Controlled Trial) evidence is lacking.

Methods: OPTIMA is a partially blinded multi-center RCT with an adaptive two-stage design. The main eligibility criteria are women and men age 40 or older with resected ER-positive, HER2-negative invasive breast cancer and up to 9 involved axillary lymph nodes. Randomisation is to standard management (chemotherapy and endocrine therapy) or to MPA-directed treatment using the Prosigna (PAM50) test. Those with a Prosigna tumour score (ROR_PT) >60 receive standard management whilst those with a low score (≤60) are treated with endocrine therapy alone. Endocrine therapy for pre-menopausal women includes ovarian suppression. The co-primary outcomes are (1) Invasive Disease Free Survival (IDFS) and (2) cost-effectiveness of test-directed treatment. Secondary outcomes include IDFS in patients with low-score tumours and quality of life. An integrated qualitative recruitment study addresses challenges to consent and recruitment and will build on experience from the feasibility study that a multidisciplinary approach at sites is important for recruitment success. Tumour blocks will be banked to allow evaluation of additional MPA technologies. Recruitment of 4500 patients over 5 years will permit demonstration of 3% non-inferiority of test-directed treatment, assuming 5-year IDFS of 85% with standard management, equivalent to a HR of 1.22. Inclusion of patients from the feasibility study will increase the power to test for non-inferiority.

Results: The OPTIMA main trial opened in January 2017. Overall recruitment (including the feasibility study) will reach 1000 in August 2018. Recruitment in Norway will commence in July 2018. Characteristics of the OPTIMA main participants recruited to 31st May 2018 are shown in the table.

**Conclusion:** OPTIMA is one of two large scale prospective trials validating the use of test-guided chemotherapy decisions in node-positive early breast cancer. It is expected to have a global impact on breast cancer treatment. Experience from the preliminary study and close engagement with centres will aid trial success.

**Funding:** OPTIMA is funded by the UK NIHR HTA Programme (10/34/501). Views expressed are those of the authors and not those of the HTA Programme, NIHR, NHS or the DoH.
Efficacy and safety of scalp cooling device for prevention of alopecia in patients with breast cancer

Asaka Kodera¹, Kaoru Ogura¹, Akinori Hattori¹, Hiroko Yukawa¹, Shiho Sakaguchi¹, Aya Matsuoka¹, Natsuko Tanaka¹, Mari Kamimura¹, Norie Jibiki², Yoshihiko Naritaka¹ and Akira Hirano¹. ¹Tokyo Women's Medical University Medical Center East, Tokyo, Japan and ²Tokyo Women's Medical University Yachiyo Medical Center, Chiba, Japan.

Background
Chemotherapy for breast cancer causes alopecia as a side effect. Some patients refuse chemotherapy because of alopecia, resulting in the omission of a standard therapy. It is believed that a scalp cooling device can prevent alopecia by promoting vasoconstriction of the scalp and reducing exposure of the hair root cells to anticancer agents. There are phenotypic differences of the efficacy of a scalp cooling device for alopecia. In fact, a Dutch scalp cooling registry reported that the success rate of scalp cooling was 51% in European women and 33% in Asian women. Therefore, we aimed to investigate the efficacy of scalp cooling device for chemotherapy-induced alopecia among Asian women with breast cancer.

Trial design
This is a phase II trial to evaluate the efficacy and safety of scalp cooling device for risk reduction of alopecia in women with stage I/II/III breast cancer treated with adjuvant/neoadjuvant chemotherapy in a single institute.

Eligibility criteria
Women diagnosed with Stage I to III breast cancer who are scheduled to receive preoperative or postoperative adjuvant chemotherapy containing anthracycline and/or taxanes are enrolled. Patients who have blood malignancies (leukemia, non-Hodgkin lymphoma, other systemic lymphoma), and cold allergy, are excluded.

Specific aims
The primary endpoint is the proportion of patients with Common Terminology Criteria for Adverse Events (CTCAE) grade 0-1 alopecia after the completion of all cycles of chemotherapy (success rate). Secondary endpoints are safety, quality of life, use of wig or cap, and success rates after the completion of all cycles of chemotherapy distinguished by anthracycline (AC) and taxane. The cooling device is the Paxman scalp cooling system. Scalp cooling was performed from 30 mins before initiation until 90 mins (25 min for taxane) after chemotherapy. Pictures of the scalp were taken at the time of the initiation of each course.

Statistical methods
Successful treatment was defined as the presence of less than 50% of hair-loss area. The sample size was calculated using the Simon method, with a type I error of 10% (two-sided) and a study power of 80%. The expected success rate is 30%, with a threshold success rate of 10%, and the required number of patients was estimated to be 19.

Present and target accrual
Patient accrual was started in April 2018 and present accrual is 3. We plan to enroll a total of 20 patients in the trial.
Phase 3 trial of carboplatin in triple negative breast cancer (TNBC) patients with residual invasive carcinoma after neoadjuvant chemotherapy (JONIE4:J-CAT trial)

Hirokazu Tanino¹, Masato Suzuki², Hiroshi Kaise³, Masaru Miyashita⁴, Takashi Chishima⁵, Mitsuhiro Hayashi⁶, Yasuo Miyoshi⁷, Manabu Futamura⁸, Shoichiro Ohtani⁹, Masayuki Nagahashi¹⁰, Tomohiko Ohta¹¹, Yoshimasa Kosaka¹², Takashi Ishikawa¹³, Yoshi Hasegawa¹⁴, Tomoyuki Kubota¹⁵, Takanori Sanga¹⁶, Tsuguo Iwatai¹⁷, Akimitsu Yamada¹⁷, Kohei Akazawa¹⁸ and Norio Kohno¹⁹.

Background: It is well known that the prognosis of non pCR TNBC patients was poor after anthracycline and taxan treatment. For such patients, capecitabine seems to be effective to reduce recurrence based on the HR 0.58 of the CREATE X trial (Masuda, N. et al. Adjuvant Capecitabine for Breast Cancer after Preoperative Chemotherapy. N Engl J Med. 376, 2147. 2017). However, the target of capecitabine is still unclear for TNBC. We classified non pCR tumors as BRCAness and Sporadic using BRCAness test (MRC-Holland, Amsterdam, the Netherlands). The recurrence rate of the BRCAness group was about 70%. Carboplatin is expected to be effective against BRCAness tumors, as it is a DNA damaging agent. In this study BRCAness can be checked just before carboplatin treatment using surgical specimens. Then the efficacy of carboplatin will be directly known to make comparison between DFS in the carboplatin group and that of the observation group.

Trial design: This is an open label, randomized phase III study that will enroll TNBC with residual invasive cancer after surgery with preoperative chemotherapy including both anthracycline and taxan. Patients are randomly assigned to either the carboplatin group or observation group. The patients in the carboplatin group are treated with carboplatin at AUC 6 and those in the observation group are observed at only 3 years.

Eligibility criteria:
1) ER and PgR<1%, HER2 0, 1+ or 2+ with FISH negative on core needle biopsy before the chemotherapy and surgical specimens.
2) Preoperative chemotherapy including both anthracycline and taxan.
3) Residual invasive cancer on breast tumors or lymph node metastasis in surgical specimens.
4) 20-79 year old women.
5) No chemotherapy within 5 years.
6) Not bilateral breast cancer, without metastasis, no prior breast cancer.
7) No severe bone marrow suppression.

Specific aims: Primary objective is DFS (Disease Free Survival). Secondary objectives are overall survival and safety.

STATISTICAL METHODS:
The 3 years recurrence rate of the observation group was estimated as 40% and hazard ratio at 0.58 based on the CREATE X trial. For both groups, 135 patients are necessary. This study is powered to approximately 80% to test the superiority of carboplatin group at a 2-sided α=0.05 using a stratified log-rank test.

Activation Date: 22nd March 2018. No patients had been enrolled till 3rd July.
REASSURE- Effects of Reiki as supportive treatment during chemotherapy of breast cancer: A prospective, randomized, controlled clinical trial

Sophie Katzendobler¹, Lisa Haunreiter¹, Lena Zander¹, Rosemarie Schmidt¹, Anne Andrulat², Katrin Münch³, Rudolf Napieralski¹, Isabella Petri⁴ and Johannes Ettl¹. ¹Klinikum rechts der Isar, Technische Universität München (TUM), Munich, Germany; ²Rotkreuzklinikum München, Frauenklinik, Munich, Germany; ³Städtisches Klinikum München Harlaching, Munich, Germany and ⁴ProReiki – der Berufsverband e.V., Berlin, Germany.

Background: Every seventh to eighth woman is diagnosed with breast cancer in her life. Next to surgery and radiotherapy most of them receive (neo)adjuvant chemotherapy, which comes along with adverse effects. Complementary and alternative medicine (CAM) like Reiki can reduce these effects. Reiki is a Far Eastern method that promotes healing on a physical, mental and emotional level and activates self-healing powers. REASSURE examines the effects of Reiki on quality of life and taxane-induced polyneuropathy during chemotherapy.

Methods: REASSURE is a prospective, randomized, controlled, two-armed clinical trial, in which patients with breast cancer receive chemotherapy and Reiki (18 times) or chemotherapy and sport (18 times). During chemotherapy and before and after every Reiki- or sport-session the patients fill out standardized questionnaires (e.g. FACT/GOG-NTX Version 4). Primary endpoint is the comparison of quality of life at the end of chemotherapy between Reiki and sport based on the FACT/GOG-NTX score by T-Test. Secondary endpoint is the comparison of the taxane-induced polyneuropathy at the end of chemotherapy between the two groups. Also short-term effects before and after the Reiki- and sport-session will be examined. A power of 1-β = 0.8, a bilateral probability of error of α = 0.05, a minimum relevant difference deltaθ = 4 and a pooled standard deviation of 11 for the two-sided T-Test result in case numbers of 2 x 120 = 240 patients.

Conclusion: REASSURE is the most comprehensive prospective study to the effects and the feasibility of Reiki on breast cancer patients during chemotherapy so far.

Since July 2015, 138 patients have been enrolled at three different centers. Currently 63 patients in total (39 patients of the Reiki-group and 24 patients of the sport-group) have completed the study. 24 Reiki-patients and 36 sport-patients are counted as dropouts because of reasons like incomplete data records, discontinuation of chemotherapy, not enough time or energy for Reiki- or sport-sessions or other reasons.

Sponsor: This is a collaborative study of the Department of Obstetrics and Gynecology, Klinikum rechts der Isar, Technische Universität München (TUM), Munich, Germany, Rotkreuzklinikum München, Frauenklinik, Munich, Germany, Department of Gynaecology, Städtisches Klinikum München Harlaching, Munich, Germany and the ProReiki – der Berufsverband e.V., Berlin, Germany.

Contact Information: For further information contact Sophie Katzendobler via sophie.katzendobler@gmail.com or the leading physician Dr. Johannes Ettl via johannes.ettl@tum.de.
Background: Annually, more than 4,000 patients are diagnosed with leptomeningeal carcinomatosis (LC) from breast cancer in the U.S. Since most therapies cannot cross the Blood-CSF-Barrier (BCB) and the Blood-Brain-Barrier (BBB), treatment options for LC are limited to local radiation and few chemotherapy agents, none of which have provided durable clinical benefit, leading to short overall survival (OS) of 3-4 months. ANG1005 is a novel peptide-drug conjugate, consisting of 3 paclitaxel molecules covalently linked to a peptide that targets the LRP-1 receptor to cross both BCB and BBB, and enter the tumor cells, where the paclitaxel is cleaved off to exert its anti-tumor activity. ANG1005 has previously shown in a phase 2 study to prolong OS in LC patients from breast cancer with brain metastases (BM) to 8 months.

Trial Design: This is an open-label, multi-center phase 3 randomized study to evaluate the efficacy of ANG1005 in HER2-negative breast cancer patients with newly diagnosed LC and documented history of previously treated BM when compared to Physician Best Choice (PBC). Hundred and fifty (150) patients will be randomized 1:1 to receive either ANG1005 experimental treatment or an Investigator assigned PBC control treatment. ANG1005 will be administered by intravenous (IV) infusion at a starting dose of 600 mg/m^2 every 3 weeks. Allowed PBC therapies include capecitabine, eribulin, or high-dose IV methotrexate. CNS disease (LC and BM) will be evaluated at screening and every 6 weeks by MRI, CSF cytology and neurological assessments according to LANO and RANO-BM criteria. Extracranial disease will be evaluated by CT scans according to RECIST at screening and every 6-12 weeks. All patients will be followed for survival every 6-8 weeks from the date of the last dose until death, lost to follow-up or consent withdrawal.

Eligibility Criteria: Eligible patients are adults (≥ 18 years old) with HER2-negative breast cancer, newly diagnosed LC and documented history of previously treated BM. Patients must be neurologically stable and have adequate blood counts, organ and bone marrow function with an ECOG status grade ≤2. Patients previously treated with ANG1005 or with known allergy to paclitaxel or its components are excluded.

Specific aims: The primary endpoint is OS. Secondary endpoints include CNS (LC and BM) progression-free survival and clinical benefit rate, 6- and 12-month OS rates, LC response rate and duration of response, OS for triple negative patients and safety.

Statistical Methods: This study is sized for testing the hypothesis of improved OS for ANG1005 versus PBC in all patients (HR=0.58, two-sided test, overall type 1 error of 5%). Interim analysis for OS (using O'Brien Fleming boundaries for efficacy and a fixed HR=1 for futility) will be performed when a total of 55 death events are reached across both arms.

Study Accrual: Target accrual is 150 patients. The study is currently planned to start in the fall of 2018.
Phase 1/2 study of topical SOR007 (nanoparticle paclitaxel ointment) for cutaneous metastasis

Julie E Lang1, Sant Chawla2, Jenny Chang3, Gere diZerega4, Rose Marie Cavanna-Mast4, Christopher Savoie2 and Mario Lacouture5. 1University of Southern California Norris Cancer Center, Los Angeles, CA; 2Sarcoma Oncology Research Center, Santa Monica, CA; 3Houston Methodist Cancer Center, Houston, TX; 4US Biotest, San Luis Obispo, CA and 5Memorial Sloan-Kettering Cancer Center, New York, NY.

Background: Cutaneous metastases are common in non-skin cancers, resulting in considerable morbidity, infection, pain, and negatively impacting quality of life. No standard of care exists for effective control of cutaneous metastases, which is a significant unmet need in oncology. Paclitaxel has shown effectiveness in the treatment of ovarian, breast, non-small cell lung, and pancreatic cancers and is approved by the United States Food and Drug Administration for the systemic treatment of many types of malignancies. We hypothesize that SOR007, or nanoparticulate paclitaxel ointment may be well tolerated and effective in the treatment of cutaneous metastases.

Trial Design: This trial is a Phase 1/2, open-label study evaluating the safety, tolerability, and preliminary efficacy of three concentrations of SOR007 (0.15%, 1.0%, and 2.0%) ointment applied topically, twice daily, to non-melanoma cutaneous metastases during a 3+3 dose-ascending or dose expansion phase. Subjects will self-apply SOR007 ointment twice daily on Days 1 to 28, to a 50 cm² area containing an eligible lesion. If a single dose limiting toxicity (DLT) is identified in the three subjects, an additional three subjects will be enrolled at the same dose level. If one or more DLT occur in the three additional subjects, dose escalation will stop and the prior dose level will be determined as the Maximum Tolerated Dose (MTD) and taken forward into the dose expansion phase. If no further DLT are identified, dose escalation will continue, until either a DLT is identified at a higher dose or the top dose of 2% is reached. Once DLT is determined, additional subjects will be enrolled in the expansion phase, to total up to 12 subjects at the top dose.

Specific Aims: 1) The primary objective of this study is to determine preliminary safety and tolerability of topical SOR007. Secondary endpoints include: 2) evaluating preliminary efficacy based on RECIST criteria, photograph documentation of lesion size in longest diameter, and objective clinical response. 3) We will evaluate potential reduction in pain at the treatment area. 4) We will determine the peripheral blood pharmacokinetics of topical SOR007 applied to cutaneous metastases.

Eligibility criteria: Male and female patients over the age of 18 with malignancies resulting in cutaneous metastasis originating from: breast, lung, head and neck, pancreatic, urinary bladder, prostate, testicular, ovarian, uterine, cervical, gastric, adrenal, thyroid, parathyroid cancers or other solid tumors which previously responded to taxane treatment are eligible to participate. Patients’ last dose of any systemic non-taxane cytotoxic chemotherapy should be completed at least one day prior to the trial. Patients’ last dose of any systemic taxane cytotoxic chemotherapy should be completed at least 4 weeks prior to the trial. Patients should be ECOG 0-2 with a minimum life expectancy of at least 3 months. Open or ulcerated wound(s) extending through the dermis are not eligible.

Statistical methods: Data will be analyzed by descriptive statistics.

Present accrual and target accrual: To date, we have enrolled 3 of a maximum of 24 subjects.
A pilot randomized usual care controlled study of yoga for persistent chemotherapy-induced peripheral neuropathy (CIPN) in breast and gynecological cancer survivors

Wanqing Iris Zhi, Melissa C Leeolou, Lauren Piulson, Patricia Chen, Clare Patterson, Tina Paul, Sujata Patil, Jun J Mao and Ting Bao. 'Memorial Sloan Kettering Cancer Center, New York, NY.

Background: CIPN is a common, painful, and debilitating side effect of many standard chemotherapy regimens. Patients with CIPN typically experience paresthesia (tingling, numbness), pain, and muscle weakness, and may exhibit significant functional decline and diminished quality of life. Our prior study showed that more than half of breast cancer survivors experience persistent CIPN up to a mean duration of 5.6 years and that this symptom is associated with a doubled fall risk. There is an urgent need to identify nonpharmacological approaches to reduce CIPN symptoms and improve cancer survivors' functional outcomes. Yoga is a mind-body modality that includes stretching, flexibility, and balance training; however, little is known about its effects on symptoms and functional outcomes among cancer survivors with CIPN.

Trial Design: We are conducting a two-arm pilot randomized usual care controlled trial in breast and gynecological cancer survivors at Memorial Sloan Kettering Cancer Center (MSK), New York, NY. Eligible subjects in the intervention arm receive one-hour Hatha Yoga classes taught twice weekly for eight weeks, and practice home-based yoga for a total of 12 weeks. Subjects in the wait list control (WLC) arm continue usual care for 12 weeks, followed by eight weeks of yoga classes and home-based yoga.

Eligibility Criteria: 1) Patients with a primary diagnosis of stage I-III breast, ovarian, uterine, or endometrial cancer; 2) moderate to severe CIPN, defined by four or greater on a 0–10 Numeric Rating Scale (NRS); 3) completion of neurotoxic chemotherapy at least three months prior; 4) no changes in anti-neuropathy medications within three months of enrollment; and 5) an ECOG performance status of 0–2.

Specific Aims: The primary endpoint is safety, feasibility, and NRS changes at eight weeks (end of treatment). The secondary endpoints include the Neuropathic Pain Scale (NPS) and Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity (FACT/GOG-Ntx) at eight, 12, and 20 weeks.

Statistical Methods: We will accrue 40 patients to get 36 patients evaluable for the primary endpoint at eight weeks. Using an ANCOVA analysis with a sample size of 36, we will be able to detect an effect size of 0.58 standard deviations (SD) of NRS (moderate effect size) between yoga and WLC assuming a NRS correlation between pre- and post-yoga of 0.5 SD. If we assume a 10% dropout rate based on our recently completed trial, we will need to recruit 20 subjects per arm (total of 40) to fall within the precision noted in the sample size calculation. We recognize that the sample size calculation was based on detecting a moderate effect between yoga and WLC and may miss small but clinically meaningful effects that can be used to design a future trial that is sufficiently powered.

Present accrual and target accrual: 40 participants. We have accrued 25 participants as of June 2018 and anticipate accrual completion by October 2018.
Phase II trial assessing accuracy of tumor bed biopsies in predicting pathologic response in patients with clinical/radiological complete response after neoadjuvant chemotherapy in order to explore the feasibility of breast-conserving surgery without surgery: NRG Oncology BR005

Mark Basik1,2, Joseph P Costantino1,3, Jennifer F De Los Santos1,4, Heidi R Umphrey1,5, Thomas B Julian1,5, Eleftherios P Mamounas6,6, Julia R White1,7, Peter C Lucas1,8, Jamie L Wagner1,9, Judy A Tjoe1,10, Alastair M Thompson11 and Norman Wolmark1,6. 1NRG Oncology, Pittsburgh, PA; 2Jewish General Hospital, Montreal, QC, Canada; 3University of Pittsburgh, Pittsburgh, PA; 4University of Alabama at Birmingham, Birmingham, AL; 5Allegheny Health Network Cancer Institute, Pittsburgh, PA; 6Orlando Health UF Health Cancer Center, Orlando, FL; 7Ohio State University Comprehensive Cancer Center, Columbus, OH; 8University of Pittsburgh School of Medicine, Pittsburgh, PA; 9University of Kansas Medical Center/ALLIANCE, Kansas City, KS; 10Aurora Sinai Medical Center/ECOG-ACRIN, Milwaukee, WI and 11University of Texas M.D. Anderson Cancer Center/SWOG, Houston, TX.

The increased use of neoadjuvant chemotherapy (NCT) has enabled higher rates of breast-conserving surgery (BCS) as well as provided prognostic information for women with breast cancer. High pathological complete response (pCR) rates question the requirement for surgery, with its attendant morbidity. In order to avoid surgery, the ability to predict pCR prior to it must be very high. Trimodality imaging alone is inadequate to predict pCR prior to surgery. We hypothesize that performing core-needle biopsy (bx) of the tumor bed in addition to trimodality imaging in patients (pts) having had a clinical complete response (cCR) will increase the ability to predict pCR. Utilizing predetermined imaging response criteria of complete or near-complete response coupled with a stereotactic core-needle bx of the tumor bed, BR005 aims to determine the predictive value of imaging followed by tumor bed bx for pCR and demonstrate its reproducibility across a multi-institutional setting.

Methods: 175 pts with operable focal or multifocal (T1-T3), stage II/IIIA invasive ductal carcinoma (all receptor subtypes) will be entered. Pts must have completed a minimum of 8 wks of standard NCT and achieved a complete or near-complete radiologic tumor response on breast imaging with mammogram, ultrasound, and MRI, and undergo BCS. Following cCR and prior to surgery, pts will undergo a stereotactic-vacuum-assisted breast bx with clip placement. The primary endpoint is the proportion of pts with post-NCT neg image-directed bx who have a pCR. Residual cancer burden scores and core bx pathology will be collected along with trimodality imaging data. Evaluation after 135 pts will allow for the possibility of early termination of the study. Results will provide the first step toward a paradigm change in the treatment of breast cancer, enabling a study to assess the criteria for successful avoidance of surgery in pts with high response rates to NCT.

Accrual as of 6-15-18: 39 (22.3%).

Support: U10CA180868, -180822, UG1CA189867.
DETECT III/IV study trial – The multicenter study program in patients with HER2-negative metastatic breast cancer and circulating tumor cells

Sabrina Krause¹, Thomas Friedl¹, Tatiana Romashova¹, Peter A Fasching², Andreas Schneeweiss³, Volkmar Müller⁵, Florin-Andrei Taran⁶, Polasik Arkadius¹, Tzschaschel Marie¹, Amelie De Gregorio¹, Franziska Meier-Stiegen², Jens Huober¹, Wolfgang Janni¹ and Tanja Fehm².
¹University Hospital Ulm, Ulm, Germany; ²Heinrich-Heine-Universität, Düsseldorf, Düsseldorf, Germany; ³University Hospital Erlangen, Erlangen, Germany; ⁴National Center for Tumor Diseases and University Hospital Heidelberg, Heidelberg, Germany; ⁵University Hospital Hamburg-Eppendorf, Hamburg, Germany and ⁶University Hospital Tübingen, Tübingen, Germany.

Background:
The collaborative DETECT study program represents one of the largest study program on metastatic breast cancer worldwide. The main objective of the DETECT trial is to evaluate the efficacy of individualized breast cancer treatment based on the presence and phenotype setting of circulating tumor cells (CTCs). Thus, the DETECT study program is one of the first clinical trial translating the role of CTC enumeration/phenotyping directly into treatment intervention within different breast cancer subtypes.

Trial design:
The DETECT III trial is a multicenter, randomized, phase III study to compare standard therapy alone versus standard therapy plus lapatinib in patients with initially HER2-negative metastatic breast cancer and HER2-positive circulating tumor cells. Patients with persisting HER2-negative circulating tumor cells (CTCs) can be included within the DETECT IV trial, a prospective, multicenter, open-label, phase II study including patients with HER2-negative metastatic breast cancer. Within the DETECT IV study setting postmenopausal patients with hormone-receptor positive metastatic breast cancer are treated with everolimus or ribociclib and endocrine therapy, while women with triple negative metastatic breast cancer or a hormone-receptor positive tumor and indication for chemotherapy receive eribulin.

Specific aims:
The DETECT study program comprises all breast cancer subtypes and therefore offers various up-to-date treatment options, generating a wealth of clinical data including long-term follow-up data, evaluated in a controlled setting of a single large clinical trial. The primary endpoint of the DETECT III trial is the comparison of patients receiving standard anticancer therapy with lapatinib and patients receiving standard anticancer therapy alone, with regard to the CTC clearance rate. The secondary objective of this trial is to assess the level of compliance to study procedures comparing the efficacy of lapatinib between given treatment groups (Progression free survival, overall response rate and dynamic of CTCs). Primary objective of the DETECT IV trial is to evaluate CTC clearance rate within the everolimus/ribociclib cohort and additionally assess progression-free survival defined as time interval from date of recruitment until progressive disease within the eribulin cohort. The main focal point of the extensive collaborative translational oncology research projects is to apply innovative biomarkers and assays focusing on molecular characteristics of CTCs. This “biological status” may give new information about CTCs potential function as liquid biopsy in order to determine their relevance for therapy prediction.
The BRandO BIO registry – A multicenter regional registry for patients with primary breast and ovarian cancer with longitudinal biobanking and evaluation of epidemiological, life style and quality of life factors

Jens Huober¹, Gabriele Nagel⁹, Andreas Rempen², Erik Schlicht³, Felix Flock⁴, Steffen Fritz⁵, Falk Thiel¹¹, Lisa Wiesmüller¹, Ricardo Felderbaum⁶, Volker Heilmann⁷, Inga Bekes¹, Visnja Fink¹, Susanne Albrecht¹, Nikolaus De Gregorio¹, Marie Tzschaschel¹, Kristina Ernst¹, Christopher Wolf⁶, Peter Kuhn¹⁰, Thomas Friedl¹, Wolfgang Janni¹ and Amelie De Gregorio¹.

¹University Hospital Ulm, Ulm, Germany; ²Diakonie-Hospital, Schwäbisch Hall, Schwäbisch-Hall, Germany; ³Staufer-Hospital, Schwäbisch Gmünd, Schwäbisch-Gmünd, Germany; ⁴Hospital Memmingen, Memmingen, Germany; ⁵Sana Clinics, Biberach, Biberach, Germany; ⁶Hospital Kempten-Oberallgäu GmbH, Kempten, Kempten, Germany; ⁷Private Practice Dr. Volkmar Heilmann, Günzburg, Günzburg, Germany; ⁸Medical Center-Dr. C. Wolf, Ulm, Ulm, Germany; ⁹Institute of Epidemiology, University Ulm, Ulm, Germany; ¹⁰Clinical Cancer Register, University Hospital of Ulm, Ulm, Germany and ¹¹Hospital Alb-Fils, Clinic am Eichert, Alb-Fils, Göppingen, Germany.

Background:
Further progress in the treatment of breast cancer will likely come from contributions of molecular biology and immunologic approaches. The search for druggable molecular aberrations may enable treatment based on the molecular profile. A better identification of patients with a high risk of relapse facilitates the selection of these pts for clinical trials investigating early therapeutic molecular-based interventions.

Trial Design:
The BRandO BIO Registry is a multi-center regional registry to record clinical, epidemiological, and biological data from patients with newly diagnosed breast and ovarian cancer at the University of Ulm, Dept. of Gynecology and 19 affiliated network hospitals and practices in the Alb-Allgäu Bodensee region (outreach area of the Comprehensive Cancer Center Ulm). Longitudinal biobanking is included with collection of paraffin-embedded samples of the primary tumor as well as blood samples at first diagnosis, after 6 and 12 months and at first relapse to isolate and investigate cell-free and germline DNA. Epidemiological, life style and quality of life (QOL) questionnaires are collected at first diagnosis, after 12, 36 and 60 months. The follow up is planned for 10 years.

Eligibility criteria:
Patients with primary newly diagnosed untreated breast or ovarian cancer of ≥ 18 years are eligible; primary metastatic untreated disease is allowed. Exclusion criteria comprise severe neurological or psychiatric disorders interfering with the ability to give an informed consent, no consent for registration, storage and processing of the individual disease characteristics and bio samples, and any malignant tumor in the last 3 years (except in situ disease).

Specific aims:
To register the majority of patients with newly diagnosed breast or ovarian cancer in all BRandO-BiO participating centers of a well-defined geographical area. To assess clinical characteristics and outcome data (event-free survival, overall survival) of these patients. To evaluate the primary tumor of all patients for mutational (druggable) aberrations. Further to assess cell-free DNA in the serial blood samples at baseline, 6 and 12 months and correlate these results with clinical outcome data as well as tumor and patient characteristics to look for early markers predicting relapse. To perform a longitudinal assessment of the patients' sociodemographic factors, comorbidities, lifestyle and QOL factors by analyzing serial questionnaires collected at recruitment and at 12, 36 and 60 months.

Present accrual and target accrual:
The BRandO BIO Registry started January 2016 in the Dept. of Gynecology, University of Ulm and February 2017 at the network hospitals and practices. Until June 2018, 1180 patients with primary breast or ovarian cancer have been enrolled. The current adherence to serial blood testing and serial questionnaires is good with a return rate of 90%. A sample size of 3000 patients is planned.

PRAEGNANT - Real world evidence, translational research, big and smart data: A prospective academic translational research network for the optimization of the oncological health care quality in the adjuvant and advanced/metastatic setting (NCT02338167)

1Hamburg-Eppendorf University Medical Center, Hamburg, Germany; 2Ulm University Hospital, Ulm, Germany; 3Erlangen University Hospital Comprehensive Cancer Center Erlangen-EMN Friedrich-Alexander University, Erlangen-Nuremberg, Germany; 4OncoConsult Hamburg GmbH, Hamburg, Germany; 5Marienhospital Bottrop, Bottrop, Germany; 6Nordwest Hospital, Frankfurt, Germany; 7University Hospital Erlangen, Erlangen-Nuremberg, Germany; 8Klinikum rechts der Isar Technical University of Munich, Munich, Germany; 9University of Tuebingen, Tuebingen, Germany; 10Charité University Hospital Berlin Campus Benjamin Franklin Department of Hematology Oncology and Tumour Immunology, Berlin, Germany; 11University of Heidelberg, Heidelberg, Germany; 12ClnSol GmbH & Co KG, Wuerzburg, Germany; 13Gustav Carus University, TU Dresden, Dresden, Germany and National Center for Tumor Diseases and TU Dresden, Dresden, Germany; 14gSUND Gynäkologie Kompetenzzentrum Stralsund, Stralsund, Germany; 15Gynäkologische Praxisklinik am Rosengarten, Mannheim, Germany; 16Klinikum Bayreuth, Bayreuth, Germany; 17 MVZ Onkologie Onkologie im Elisenhof, Munich, Germany; 18 Medizinisches Zentrum Bonn, Bonn, Germany; 19Breast Center and CCC Munich University Hospital Munich, Munich, Germany; 20Martin-Luther-University Halle-Wittenberg, Halle, Germany; 21Helios Clinics Berlin Buch, Berlin, Germany; 22University Hospital, Duesseldorf, Germany; 23National Center for Tumor Diseases and Heidelberg University Hospital Heidelberg, Heidelberg, Germany and 24Oncology Practice at Bethamien Hospital, Frankfurt, Germany.

Background
During the last decades the treatment of advanced breast cancer (ABC) patients has improved due to a variety of new treatment strategies. Nevertheless, many ABC patients are faced with limited prognosis, and their treatment remains a challenge. New targeted therapies complement the well-established treatment options for ABC (CDK4/6 inhibition, anti-endocrine, chemotherapy, antibody based and bone related therapies), leading to improved treatment regimens tailored to the needs of special patient sub-populations.

SPECIFIC AIMS/TRIAL DESIGN
The PRAEGNANT network study is conducted as an academic, prospective registry and diagnostic translational study, accompanied by biomaterial collection. The pilot phase in more than 60 centers aims at including 3500 ABC patients. The primary objective is to discover biomarkers, which predict progression free survival (PFS). Secondary objectives include overall survival (OS), breast cancer specific survival, objective response rate, patient reported outcomes (PRO), description of therapies used in the metastatic setting, therapy adherence, health economics for patients with ABC, incidence of (serious) adverse events and big data/machine learning algorithms. The exploratory objectives comprise correlations of gene alterations and their influence on OS, PFS, side effects and PRO. Exploratory biomarkers are assessed at baseline and at every change of therapy. These biomarkers include gene expression profiling of the primary tumor and corresponding metastasis, somatic mutations (measured in the tumor and in circulating tumor DNA), germline genetic variations, epigenetic changes and miRNA variations. Furthermore, plasma and serum markers are assessed. If actionable molecular alterations are detected patients are informed and recruited into suitable studies if available.

ELIGIBILITY CRITERIA:
Any adult patient (>18 years) with the diagnosis of ABC and who is willing and able to sign the informed consent can be enrolled.

STATISTICAL METHODS/TARGET ACCRUAL:
The PRAEGNANT study as a prospective real world registry and diagnostic translational study aims to identify biomarkers in ABC patients, which may predict PFS. Target accrual for the pilot phase is 3500 patients. Each patient will be documented for up to 36 months with an estimated median PFS for all patients of 11 months across all treatment lines.
Exploration of factors associated with imminent risk of late recurrence in hormone receptor positive breast cancer

Katarzyna J Jerzak¹, Dave W Cescon², Stephen K Chia³, Scott Bratman³, Marguerite Ennis³, Vuk Stambolic³, Martin Chang⁴, Ryan Dowling⁴ and Pamela J Goodwin⁴. ¹Sunnybrook Research Institute, University of Toronto, Toronto, ON, Canada; ²Princess Margaret Cancer Centre Research Institute, University of Toronto, Toronto, ON, Canada; ³Vancouver Coastal Health Research Institute, University of British Columbia, Vancouver, BC, Canada and ⁴Lunenfeld-Tanenbaum Research Institute, University of Toronto, Toronto, ON, Canada.

Research objectives: To conduct a prospective observational study of patient and tumor-related factors in women with high risk hormone receptor (HR)+/HER2- breast cancer (BC) following at least 5 years of adjuvant hormonal therapy, in order to identify risk factors for imminent recurrence.

Rationale: Many of the life-threatening BC recurrences in women with HR+HER2- BC take place more than 5 years post-diagnosis, often after completion of adjuvant hormonal therapy. The identification of a biomarker(s) for late BC recurrence could lead to interventional trials to evaluate preventive therapies. We will evaluate whether the presence of blood-based biomarkers [(i) Circulating Tumor Cells (CTCs), (ii) circulating tumor DNA (ctDNA), (iii) tumor markers (CA 15-3, CEA)] and patient factors may predict BC recurrence.

Trial design: A prospective cohort of eligible women with previously treated HR+HER2- BC who have not experienced a distant recurrence will be enrolled; patient and circulating factors will be measured annually until distant recurrence or study completion. Host factors (including BMI, lifestyle, medical illness, surgery, trauma and stress, as well as circulating PlGF, VEGF-1 and inflammatory markers) that may contribute to exit of BC cells from dormancy will also be assessed.

The primary outcome is distant BC recurrence. Any BC event, including loco-regional recurrence, new breast or other primary cancer will be evaluated as a secondary endpoint. Outcomes will be ascertained by regular self-report (via annual telephone calls) and/or physician report and confirmed by medical record review.

Key eligibility criteria: i) Diagnosis of ER and/or PR positive (either or both 10% positive), HER2 negative invasive BC, ii) predicted >1.5-2% annual risk of recurrence (T2, T3 or T4 with any N+;T1 N2+; T2N0 or T1 N1 cancers with high risk genomic scores), iii) receipt of adjuvant endocrine therapy for at least 4 years, with discontinuation planned in the next 12 months or completion of endocrine therapy within the last 5 years, iv) prior adjuvant chemotherapy, targeted therapy and bone targeted therapies are allowed provided they have been completed.

Specific aims: 1) Determine if the presence of (i) CTCs, (ii) ctDNA, (iii) CA15-3 and CEA are associated with imminent risk (within 1-2 years) of distant recurrence in the study population. 2) Identify host factors associated with these blood-based biomarkers, as well as clinical outcomes.

Statistical methods: A matched case control design (matching for time since completion of adjuvant hormone therapy, baseline T, N and grade) will be used to investigate associations of key study variables with imminent risk of distant recurrence within the next 1-2 years. Measurements of patients who do versus do not recur will be compared over the 1-2 years prior to relapse. Each variable will be allocated one third of a study-wide type one error of 0.05 (2-sided). ROC analyses and multivariable modelling will be used to optimize sensitivity, specificity, PPV and NPV. Available questionnaire data will be summarized at all time-points to generate descriptive survivorship data.

Accrual: Starting in August 2018, we plan to recruit 1,000 patients over 2 years at selected Canadian cancer centres.
Biomarker study of patients with HER2-negative metastatic breast cancer receiving combination therapy with nivolumab, bevacizumab and paclitaxel as first-line treatment (WJOG9917BTR)

Yukinori Ozaki¹, Shigehisa Kitano², Koji Matsumoto³, Masato Takahashi⁴, Toru Mukohara⁵, Manabu Futamura⁶, Norikazu Masuda⁷, Junji Tsurutani⁸, Kenichi Yoshimura⁹, Hironobu Minami¹⁰ and Toshimi Takano¹. ¹Toranomon Hospital, Tokyo, Japan; ²National Cancer Center, Tokyo, Japan; ³Hyogo Cancer Center, Hyogo, Japan; ⁴NHO Hokkaido Cancer Center, Hokkaido, Japan; ⁵National Cancer Center Hospital East, Chiba, Japan; ⁶Gifu University, Gifu, Japan; ⁷NHO Osaka National Hospital, Osaka, Japan; ⁸Kindai University, Osaka, Japan; ⁹Kanazawa University Hospital, Kanazawa, Japan and ¹⁰Kobe University School of Medicine, Hyogo, Japan.

Background: In recent years, anti-PD-1 antibody, an immune checkpoint inhibitor, has been developed for the treatment of various types of cancer, including breast cancer. Synergistic effects of nivolumab, paclitaxel and bevacizumab are expected, based on various preclinical data, when these drugs are administered in combination. A biomarker study is ongoing to evaluate the immune status of patients participating in the NEWBEAT trial, which is a phase II trial of nivolumab + paclitaxel + bevacizumab therapy as first-line treatment for patients with metastatic or recurrent HER2-negative breast cancer. Methods: HER2-negative breast cancer patients from the WJOG9917B (NEWBEAT) trial are enrolled in this biomarker study. To explore new biomarkers for combined treatment of breast cancer with immune-checkpoint inhibitors and anti-vascular endothelial growth factor antibodies, we propose to conduct multicolor immunohistochemistry (IHC) assays for immunomonitoring of the intra-tumor environment, such as the expressions of PD-L1, CD4 and CD8. Blood samples are collected before the start of treatment and at four time-points during the treatment, to determine, using a multicolor flow cytometry panel, the numbers of circulating immunosuppressive cells, such as regulatory T cells, myeloid-derived suppressor cells and tumor-associated macrophages (M2). In the NEWBEAT trial, patients receive nivolumab 240 mg/body on days 1 and 15, paclitaxel 90 mg/m² on days 1, 8 and 15, and bevacizumab 10 mg/kg on days 1 and 15 every 4 weeks until disease progression. The primary endpoint is the objective response rate, and the key secondary endpoints include progression-free survival, overall survival, and toxicity of the protocol treatment. A total of 51 patients will be enrolled and the enrollment period will be one year. This trial opened to accrual in February 2018. Clinical trial registry number: UMIN000029590
**Background:** In node negative and 1-3 positive nodes breast cancer patients with hormone receptor positive (HR+), HER2-negative (HER2-) early-stage breast cancer the indication for chemotherapy is based on clinical and pathologic risk stratification (tumor size, nodal status, grading, quantitative ER, progesterone receptor and Ki67). For further decision-making, the EndoPredict test, which combines a molecular signature with the clinical risk factors tumor size and nodal status, stratifies patients into “low risk” or “high risk” groups. Level I-B- evidence demonstrates, that EndoPredict predicts the 10 year cumulative risk of relapse and metastases in patients with HR+/HER2- primary breast cancer with endocrine treatment.

**Aim:** In the RESCUE-Trial we document distant metastasis-free survival (DMFS), disease free survival (DFS) and overall survival (OS) events in patients who had an EndoPredict test. The primary objective is to show that 10-year DMFS of patients tested as “low risk” by EndoPredict and treated with adjuvant endocrine therapy alone is >90 %. Secondary endpoints among others include DMFS, DFS, OS in patients with EPclin “low risk” versus “high risk”. Also the proportion of patients whose treatment was concordant and non-concordant with EndoPredict test results, will be analyzed for survival. The prognostic performance of classical prognostic factors (like tumor size, nodal status, grading, quantitative ER, progesterone receptor and Ki67 level) with respect to survival will also be assessed.

**Eligibility:** Patient with HR+/HER2- primary invasive breast cancer stage I/II and T1 to T3 with 0 to 3 positive lymph nodes will be eligible, if they had an EndoPredict test within three months before inclusion.

**Methods:** The EndoPredict test results, tumor board decision and anti-tumor therapy will be assessed. After one year, annually (for 10 years), patients will be evaluated for treatment compliance, recurrence, metastases, and survival. The primary endpoint will be analyzed by a Kaplan-Meyer estimate for which a one-sided lower 95 % confidence interval will be given. Several secondary endpoints will be assessed in three interim analyses after completion of the 1st, 3rd, 5th year and then finally after 10 years.

**Accrual:** Start of accrual is planned for July 2018. At least 26 sites in Germany and one site in Switzerland will be active.

**Sponsor:** The study is sponsored by the North-Eastern-German Society of Gynecological Oncology (NOGGO) e.V.

**Contact Information:** For further information, contact NOGGO via studies@noggo.de or the leading physician Dr. Johannes Ettl via johannes.ettl@tum.de.
A phase IIIb, open-label, local, multicenter study of the molecular features of postmenopausal women with hormone receptor-positive (HR+) HER2-negative advanced breast cancer on first-line treatment with ribociclib and letrozole (BioItaLEE)

Michelino De Laurentiis, Grazia Arpino, Giampaolo Bianchini, Luca Malorni, Daniela Castelletti, Roberta De Vecchi and Donatella Grasso. ¹Istituto Nazionale Tumori Fondazione G Pascale, Naples, Italy; ²Università Federico II, Naples, Italy and ³Ospedale San Raffaele, Milan, Italy.

Background: characterizing the molecular features associated with prolonged benefit from CDK 4/6 inhibitors in HR+ HER2- BC and the acquired genomic alterations following treatment progression remains an unmet need and is crucial for leveraging the efficacy of CDK4/6 inhibitors and for elucidating resistance mechanisms. Identifying pre-treatment or pharmacodynamic predictive markers of treatment benefit, as well as predictive markers of toxicity by correlating pharmacogenomics with adverse events, could help physicians to select patients who may benefit the most from these therapies and improve the clinical management.

Trial design: this is an Italian, multicenter, open-label, single-arm trial (NCT03439046) enrolling approximately 350 HR+ HER2-aBC first line patients in 48 sites. Patients are treated with ribociclib and letrozole and eligibility criteria are similar to the MONALEESA-2 trial. Patients will be followed for safety and efficacy outcomes. An extensive prospective collection of biological samples at different time points will be performed as follow: whole blood and plasma at baseline, cycle 1-D15, cycle 2-D1, at first imaging evaluation, at cycle 24-D1, as well as upon progression of disease; newly obtained tissue biopsies at baseline and at progression; a buccal swab for pharmacogenetics at baseline. Efficacy and safety data will be collected for all patients.

Aims: the primary objective of this study is to identify circulating tumor DNA (ctDNA) alterations at baseline, to describe their evolution during treatment and to evaluate the association with clinical outcome. An optimized Next Generation Sequencing approach for the detection of low abundance events in ctDNA will be adopted. Single nucleotide variants and copy number alterations in a customized panel of genes relevant for BC will be analyzed. Secondary objectives include the evaluation of: serum thymidine kinase 1 activity over time as blood marker of early response; ctDNA alterations across different patient profiles and clonal evolution of ctDNA alterations under treatment; ctDNA alterations at time of tumor progression; correlation between mutational status detected in ctDNA and matched tissue samples; features of tumor microenvironment before and after treatment; association of pharmacogenomics patterns with adverse events and clinical outcomes. Clinical efficacy and safety of ribociclib + letrozole will be correlated with all biological endpoints.

Statistical methods: the study is descriptive in nature and no formal statistical testing is necessary or applicable. Sample size is aligned with other biomarker studies and is based on a feasibility analysis of the trial and relative timelines.

Present accrual: The first study patient was screened in Feb 2018, as in June 2018, 126 patients have been screened and 78 patients have been enrolled.
MammaPrint, BluePrint, and full-genome data linked with clinical data to evaluate new gene expression profiles (FLEX)

Adam M Brufsky¹, Jennifer A Crozier², Ian Grady³, Thomas Lomis⁴, Pat Whitworth⁵, Esther Rehmus⁶, Gordon Srkalovic⁷, Laura Lee⁸, Peter Blumencranz⁹, Paul Baron¹⁰, Blanche Mavromatis¹¹, Sarah Untch¹², Lisa Blumencranz¹², Erin B Yoder¹², William Audeh¹³ and FLEX Investigators Group¹². ¹University of Pittsburgh Medical Center Magee Womens Hospital, Pittsburgh, PA; ²Baptist MD Anderson Cancer Center, Jacksonville, FL; ³North Valley Breast Clinic, Redding, CA; ⁴Valley Breast Care, Van Nuys, CA; ⁵Nashville Breast Center, Nashville, TN; ⁶Akron General Medical Center, Akron, OH; ⁷Sparrow Cancer Center, Lansing, MI; ⁸Comprehensive Cancer Center, Palm Springs, CA; ⁹Morton Plant Hospital, Clearwater, FL; ¹⁰Breast & Melanoma Specialists of Charleston, Charleston, SC; ¹¹Western Maryland Health Systems, Cumberland, MD and ¹²Agendia, Irvine, CA.

BACKGROUND: Genomic signatures are revolutionizing the definition, identification, and treatment of breast cancer subtypes. The ability of genomic signatures to enable fine grained stratification of breast cancers to the granular disease level is still generally untested because of the difficulties in aggregating large clinical data sets. In order to stratify breast cancers into actionable subtypes both the full genome data and clinical data must be collected for patients at scale.

DESIGN & METHODS: FLEX is designed as a novel, large-scale, population based, prospective registry. All patients with stage I-III breast cancer who receive MammaPrint (MP) or BluePrint (BP) testing on a primary breast tumor are eligible. FLEX utilizes an adaptive design which enables additional study arms at low incremental effort and cost by allowing targeted substudies to be added. Patients who are enrolled in the initial study will also be eligible for inclusion in any additional study arm where they meet all criteria. Additional study arms and substudies may be investigator-initiated.

SPECIFIC AIMS:
Primary: Create a big-data registry of full genome expression data and clinical data to investigate new gene associations with prognostic and/or predictive value.
Secondary: Generate hypotheses for targeted subset analyses and trials based on full genome data. To date the following substudies have been proposed:

DR. JENNIFER A. CROZIER, BAPTIST MD ANDERSON CANCER CENTER
(1) MP and BP in male breast cancer TYPE: SUBSTUDY; NO ADDITIONAL CONSENT (ICF) REQUIRED. ARMS: ALL (2) MP BP evaluation in breast cancer patients ≥70. TYPE: SUBSTUDY; NO ADDITIONAL ICF REQUIRED. ARMS: ALL (3) FG evaluation in ILC. TYPE: SUBSTUDY; NO ADDITIONAL ICF REQUIRED. ARMS: ALL (4,5) MP BP relation to PR positivity, Ki67. TYPE: SUBSTUDY; NO ADDITIONAL ICF REQUIRED. ARMS: ALL (6) MP BP in metaplastic breast cancer. TYPE: SUBSTUDY; NO ADDITIONAL ICF REQUIRED. ARMS: ALL

DR. ADAM M. BRUFSKY, UNIVERSITY OF PITTSBURGH MEDICAL CENTER MAGEE WOMENS HOSPITAL
(1) Response to standard chemotherapy regimens in clinically ER+/PR+/HER2+ (triple positive) patients according to BP molecular subtypes. (2) Expression signatures by response to bisphosphonates in ER+ patients receiving adjuvant therapy, or for osteoporosis after primary treatment. (3) Gene expression in breast cancer patients with obesity. TYPE: SUBSTUDY; DUAL ICF UTILIZED. ARMS: NEOADJUVANT AND ADJUVANT

DR. IAN GRADY, NORTH VALLEY BREAST CLINIC
Impact of genomic risk classification on travel time to receive breast cancer care. TYPE: SUBSTUDY; NO ADDITIONAL ICF REQUIRED. ARMS: ALL

DR. THOMAS LOMIS, VALLEY BREAST CARE
Complementary data collection for patients participating in the ODM-201 trial. FLEX provides gene expression for exploratory and signature discovery. TYPE: COMPLEMENTARY; DUAL ICF UTILIZED. ARM: NEOADJUVANT

DR. PAT WHITWORTH, NASHVILLE BREAST CENTER
Genomic reclassification of large tumors eligible to receive NCT therapy. TYPE: SUBSTUDY; NO ADDITIONAL ICF REQUIRED. ARM: NEOADJUVANT

ELIGIBILITY, ACCRUAL
FLEX will enroll a minimum of 10000 patients aged ≥18 with stage I-III breast cancer who sign ICF. Enrollment began April 2017 and 623 patients have been enrolled as of June 2018.
Molecular testing for minority patients with or at high risk for cancer

Rajbir Singh¹, Maliyah Al Bayan¹, Saritha Kadari¹, Marldine N Nganteh¹, Marche’ Jacksonm¹, Lanique M Woodson¹, Abdullah S Shamsuddin¹, Brenda Y Lemus¹, Sidharth Pratap¹, John J Murray¹, Samuel E Adunyah¹ and Philip E Lammers¹. ¹Meharry Medical College, Nashville, TN.

PURPOSE: Meharry Medical College is a participant in eMERGE (Electronic Medical Records and Genomics); a multicenter network sponsored by NHGRI/NIMHD with the primary goal to develop, disseminate, and apply approaches to research that combine biorepositories with electronic medical records (EMR) for genomic discovery and medicine implementation research. The consortium also focuses on ethical issues involving privacy, confidentiality, and interaction with the broader community. Individual institutions created protocols around research questions individualized to their populations.

METHODS: We enrolled 500 African Americans with or at high-risk for the four most common cancers (prostate, colorectal, breast, lung) to examine possible genetic and proteomic differences to account for health disparities in this population. We will perform DNA, RNA, and proteomics analyses pertinent to these cancers and obtain corresponding clinical history from the EMR with planned long-term follow up.

RESULTS: 500 subjects (211 female) were enrolled over 11 months from Nashville General Hospital including the following cancer/at-risk participants (Breast 59/37; Colorectal 17/128; prostate 31/136; lung 16/76). Most individuals stated that they participated for potential benefit to themselves, family members, or humankind and only 11 percent of potential participants declined. Little concern has been voiced for providing samples for genetic analysis. A genetic counselor will meet with the participants that are found to have pathogenic or likely pathogenic mutations while study investigators will share results with those that are not found to have mutations. Participants will be queried regarding understanding of the genetic testing results and followed for one year to evaluate if they underwent recommended testing and to follow for cancer outcomes.

CONCLUSION: The inclusion of diverse groups in genomic research is critical to identify possible reasons for health disparities and to study the understanding of genetic testing and ethical issues surrounding this topic. In this study, African-Americans are participating willingly in clinical research to examine possible genetic and/or social bases for cancer disparities.

ACKNOWLEDGEMENT: NIMHD (U54MD007593) to the Meharry Translational Research Center (MeTRC); National Human Genome Research Institute (NHGRI); National Institute of Allergy and Infectious Disease (NIAID).
CBCSG-040: A randomized multicenter, open, prospective, controlled study-comparison of the safety of immediate one-stage implant based breast reconstruction (IBBR) versus two-stage expander-implant IBBR augmented with TiLoop® bra

Benlong Yang¹ and Jiong Wu¹. ¹Fudan University Shanghai Cancer Hospital/Institute, Shanghai, China.

A research from Netherlands comparing two-stage implant-based breast reconstruction with immediate one-stage implant-based breast reconstruction augmented with an acellular dermal matrix was published on Lancet Oncology in 2017. It showed that immediate one-stage IBBR with ADM was associated with more severe adverse events. However, the ADM used in this research was heterogeneous. And there were limitations in the research. An Austrian perspective study compared the safety, cosmetic outcomes and satisfaction in patients received IBBR with ADM or TiLoop® Bra. Results showed that there was no statistical difference between these two groups. A German multicenter, retrospective study focusing on IBBR with TiLoop®Bra showed that overall complication rates of one-stage and two-stage method were 29.2% and 27.6% respectively. So far, the results of these prospective and retrospective studies have inconsistent results and we find that there is a lack of high quality evidence focusing on comparing one-stage and two-stage implant-based breast reconstruction with TiLoop®Bra.

Our study is the first prospective randomized study assessing the safety and patient-reported outcomes of immediate one-stage IBBR compared with those of two-stage IBBR with TiLoop® Bra. Our hypothesis is that one step method is not inferior to two step method in implant based breast reconstruction following mastectomy using TiLoop® Bra. In the present randomized multicenter, open, prospective, controlled study, patients were enrolled at six hospitals in different places of China. All patients will undergo Skin Sparing Mastectomy (SSM)/Nipple Sparing Mastectomy (NSM) with one-stage or two stage IBBR with TiLoop® Bra. Randomization was done electronically, stratified per center in each hospital to achieve roughly balanced groups. The study was open label, and surgeons and patients were informed about the allocated treatment at least 3 days before surgery. Based on earlier experience, we calculated that the surgical complication rate was approximately 30 percent in the one-stage group and 25 percent in the two-stage group. Consider a dropout rate of 5%, a total of 450 patients, with 225 in each group, are needed.

The present study aims to compare the safety of immediate implant reconstruction following mastectomy using TiLoop® Bra (one step method) versus immediate-delayed implant reconstruction (two step method). The primary endpoint is the rate of complication between the two groups in one year after surgery. The secondary endpoint is assessing the quality of life, patient satisfaction, aesthetic score of reconstructed breast, type of additional surgery following breast reconstruction, angiopathology-related assessment of TiLoop® Bra. The recording surgery complications including hematoma, seroma, burn wound, redness without signs of infection, wound infection, skin necrosis, implant exposure, the implants removal and contracture of cyst. All the complications are staged according to Clavien-Dindo score system.

The study is expected to end the enrollment in 2019. We are looking forward to deliver the latest result in the future.
Thoracic interfascial nerve blocks versus paravertebral block for improving quality of recovery after breast cancer surgery: A randomized, double-blind, non-inferiority trial

Hajime Abe¹, Toshinori Horiuchi¹, Atsuko Teramoto¹, Yoshihito Tanaka¹, Yumiko Takei¹ and Toshihiro Nagahata¹. ¹Bell Land General Hospital, Sakai, Osaka, Japan.

Background: Chronic pain after breast cancer surgery has harmful effects on patients' daily life. Paravertebral block (PVB) can prevent not only acute but chronic pain after breast cancer surgery, although the block is not easily put into practice because of technical difficulty or necessity to change patients' position. Thoracic interfascial nerve blocks (TINB) have been reported that it gives similar analgesic efficacy as PVB as with fewer risks, however there are no reports comparing analgesic efficacy of PVB with TINB. Although there are several scales evaluating postoperative pain including visual analog scale (VAS) or numerical rating scale, Quality of Recovery (QoR) have been set up to assess the impact of postoperative morbidity on patients' ability to return to normal function and quality of life. Among those assessment scales, QoR-40 has been mainly applied. It consists of 40 questions including five dimensions: psychologic support, physical comfort, emotional state, physical independence, and pain. There is a report suggesting that PVB improve QoR-40 after ambulatory breast tumor resection.

Methods: This is a single center single arm phase 2 study for early breast cancer patients. Exclusion criteria are pregnant and parturient women, allergy to local anesthetics, significant psychiatric or mental disorders, and patients with chronic pain. All blocks are subjected to ultrasound guidance. Patients were randomized to receive PVB with 40 ml ropivacaine or TINB with 60 ml ropivacaine. TINB consisted of modified PECS II block and transversus thoracic muscle plane block. For assessment of QoR, QoR-40 score which was consisted of 5 elements including postoperative pain was used. The trial was activated in July 2016.

Statistical Method: We conducted a pilot study on 16 patients who received a PVB during breast cancer surgery. Based on the standard deviation (SD) of QoR-40 on postoperative day (POD) 1, the SD was set to 7.2. Since the non-inferiority limit needs to be reduced to about half as much as the effect quantity used in the average value superiority test, it is set to 8, which is half of the effect quantity 16 in the pilot study. When one-sided test with α error = 0.025 and β error = 0.2, about 13 cases in each group are required. Given that dropout rate is about 30-40%, 18 cases in each group were taken as the number of subject cases.

Results: Thirty-six patients were accrual, 18 of PVB group and 18 of TINB group. Two patients declined the trial, 36/38 (95%) acceptors completed the trial. Total of QoR-40 scores on POD 1 was designated as the primary outcome. For secondary outcomes, both QoR-40 score and pain score were assessed on POD 3 and in postoperative month(s) 1, 3, 6, 12. Other secondary outcomes included pain score by POD 1, incidence of rescue analgesia, time to rescue analgesia, incidence of nausea and vomiting. All patients provided written informed consent before undergoing any study-related procedures.

Conclusions: This trial will provide non-inferiority that TINB preserve the effect of QoR as good as PVB after breast cancer surgery.

A prospective pilot study of simultaneous robotic assisted nipple sparing mastectomy and immediate reconstruction

Endoscopic breast surgery was expected to be an adequate technique to complete cancer clearance and preservation of the patient's body image. However, this technique has limitations including incomplete internal movements and unstable vision of a two dimensional camera due to inflexible endoscopic instruments especially during the skin flap formation. High resolution, ten-fold image magnification, and three-dimensional optics of robotic surgery help overcome the limitations of endoscopic surgery, and thus robotic surgery has been adopted in a wide range of intracorporeal procedures including breast surgery. However, few studies have evaluated feasibility and safety of robotic assisted nipple sparing mastectomy (RANSM) and immediate breast reconstruction (IBR) for the treatment of breast cancer. There were not any investigation to assess patients' satisfaction of cosmetic effect after performing RANSM and IBR. This study is aim to verify the feasibility and the safety of RANSM and IBR and to analyze cosmetic effect of the procedure and satisfaction of patients. The target number of enrollments is 15 patients. Patients who are diagnosed with early breast cancer or BRCA 1/2 mutation carriers are enrolled. Female patients over 20 years old who are candidates to preserve nipple areolar complex and considered to perform reconstruction with implants are prospectively collected. Written informed consents are mandatory. Patients who are considered the high possibility of postoperative radiation therapy according to preoperative stage are not included in this study. We exclude patients who want to undergo other methods of breast reconstruction than breast reconstruction with implants. Patients will undergo RANSM and IBR through a single axillary skin incision simultaneously. Regular follow-up at 1 month and 6 months after RANSM and IBR is scheduled to record recovery of a patient, amount of a drain, date of drain removal, and postoperative complications. Patient satisfaction questionnaire will be completed on the last follow-up day. To evaluate the safety of robotic assisted surgery, the oncologic safety (margin status of nipple areolar complex), postoperative recovery of a patient, and postoperative complications are investigated. We compare preoperative and postoperative 6 month photographs of patients and estimate the surgical outcome by objective indicators to evaluate the cosmetic grading by plastic surgeons. Patients’ satisfaction are assessed by questionnaire (BREAST-Q) at the 6-month visit.
Towards omitting breast cancer surgery in patients with pathologic complete response after neoadjuvant systemic therapy: The MICRA trial (minimally invasive complete response assessment)

Marieke EM van der Noordaa1,2, Frederieke H van Duijnhoven1, Claudette E Loo1, Ariane van Loevezijn1, Erik van Werkhoven1, Koen K van de Vijver3,1, T Wiersma1, Hillegonda AO Winter-Warnars1, Gabe S Sonke1 and Marie-Jeanne TFD Vrancken Peeters1.
1Antoni van Leeuwenhoek Hospital / Netherlands Cancer Institute, Amsterdam, Netherlands; 2University of California San Francisco, San Francisco, San Francisco and 3Ghent University Hospital, Ghent, Belgium.

Background
Improvements in neoadjuvant systemic therapy (NST) for breast cancer patients have led to increasing rates of pathologic complete response (pCR). Breast-conserving surgery (BCS) after NST is considered safe, despite the fact that the original tumor bed is not entirely excised. It can therefore be hypothesized that breast surgery could be omitted in patients achieving pCR. However, since imaging modalities are insufficiently accurate to predict pCR after NST, the need for surgery is unchanged. The MICRA trial is designed to determine the value of ultrasound guided biopsy of the breast in identifying pCR after NST. The ultimate aim of our study is to eliminate surgery of the breast in patients achieving pCR, consequently improving quality of life of these patients.

Trial design
The MICRA trial is a multi-center observational prospective cohort study. Inclusion and exclusion criteria are presented in table 1. In all patients receiving NST, a marker is placed in the center of the tumor area pre-NST. Magnetic resonance imaging (MRI) is performed pre-NST and just before or after the last course of NST. Patients with radiologic complete response (rCR; complete absence of pathologic contrast enhancement) or partial response (rPR, 0.1-2.0 cm residual contrast enhancement, ≥30% decrease in tumour size) are eligible for participation. In these patients, 8 ultrasound guided biopsies are obtained in the region surrounding the marker: 4 central (<0.5 cm) and 4 peripheral biopsies (0.5-1.5cm). Hereafter, conventional surgery is performed (BCS or mastectomy) and pathology results of the biopsies and resected specimen are compared. Pathology findings are scored using Miller-Payne criteria. To evaluate the quality and representativeness of the biopsies, biopsies are categorized according to length and pathology results.

Statistical analysis and accrual
The primary endpoint of the trial is the false-negative rate (FNR) of the biopsy procedure. If the true FNR is 3%, 130 patients without pCR in specimen are sufficient to show that the FNR does not exceed 8% using a one-sided binomial test with a significance α-level of 0.05. With an expected average pCR rate of 65%, 375 patients with rCR will be included. In the rPR-group the expected pCR rate is 12% and therefore 150 patients will be included. In total 525 patients will be included. Until now, 144 patients have been included.

Conclusion
The ultimate aim of the MICRA trial is to eliminate surgery of the breast in patients achieving pCR, by identifying pCR with use of ultrasound guided biopsy. In this scenario, local therapy in patients with pCR would be restricted to radiotherapy.

A randomized controlled trial comparing post-operative intensive follow-up with standard follow-up in high-risk breast cancer patients (JCOG1204: INSPIRE)

Takashi Hojo¹, Norikazu Masuda², Taro Shibata³, Tomonori Mizutani⁴, Tadahiko Shien⁴, Takayuki Kinoshita⁵, Tsuguo Iwatani⁶, Chizuko Kanbayashi⁶, Dai Kitagawa⁷, Michiko Tsuneizumi⁸ and Hiroji Iwata⁹. ¹National Cancer Center Hospital East, Chiba, Japan; ²NHO Osaka National Hospital, Osaka, Japan; ³National Cancer Center Hospital, Tokyo, Japan; ⁴Okayama University Hospital, Okayama, Japan; ⁵St. Marianna University School of Medicine, Kanagawa, Japan; ⁶Niigata Cancer Center, Niigata, Japan; ⁷Cancer Institute Hospital, Tokyo, Japan; ⁸Shizuoka General Hospital, Shizuoka, Japan and ⁹Aichi Cancer Center Hospital, Nagoya, Japan.

**Background:** The standard follow-up after surgery for breast cancer includes periodic interviews, clinical examinations, and mammography, but many institutions are conducting intensive follow-up including periodic computed tomography (CT), magnetic resonance imaging (MRI), and bone scintigraphy in the world, despite the lack of evidence to support this approach. While intensive follow-up may contribute to prolonged survival through earlier diagnosis and treatment of relapse, it has the disadvantages of high effort and costs placed on patients (pts) and healthcare workers, radiation exposure for imaging examinations, and overtreatment owing to false-positive results. Although past two randomized trials could not show significant difference in overall survival (OS), as imaging methods have remarkably improved, leading to the earlier detection of relapse, and medical therapies have remarkably improved in recent years, randomized controlled trials are needed to confirm whether intensive follow-up can really prolong survival sufficiently to offset these disadvantages in high-risk breast cancer pts.

**Trial design:** This study is a multi-institutional two-arm open label randomized controlled phase III trial being conducted with the participation of 42 hospitals belonging to the Breast Cancer Study Group of Japan Clinical Oncology Group. Eligible pts are randomized either to the intensive follow-up group or to the standard follow-up group; the former will undergo physical examination, bone scintigraphy, chest and abdominal CT, brain MRI/CT and frequent tumor markers, whereas the latter will undergo physical examination at the same frequency and tumor markers will be evaluated once a year. Mammography once a year is planned for both groups. This trial has been registered at the UMIN Clinical Trials Registry as UMIN000012429.

**Eligibility criteria:** High-risk breast cancer pts, who are expected to have recurrence rates of over 30% within 5 years after surgery. The main inclusion criteria are as follows: four or more axillary nodal metastases in the estrogen receptor (ER) positive pts without neoadjuvant chemotherapy (NC), axillary node metastases in ER-negative pts without NC, axillary nodal metastases in ER-positive pts with NC, histologically proven residual invasive cancer in the breast or axilla in ER-negative with NC.

**Specific Aims:** The primary endpoint is OS, and secondary endpoints are disease-free survival, relapse-free survival, distant metastasis-free survival, OS in intrinsic subtypes, actual number of implemented examinations, compliance with pre-specified examinations, and adverse events.

**Statistical methods:** The primary endpoint will require a total of 538 events to be assessed in order to obtain a statistical power of 80% with a one-sided significance level of 0.05. Thus, the planned sample size to compare the two survival curves is set at 1500 pts, assuming an accrual time of 6 years and a follow-up time of 7 years according to the Schoenfeld and Richter's method.

**Present accrual and target accrual:** The trial was activated in November 2013. 773 pts have been enrolled by the end of June 2018.

**Contact:** Principal investigator Takashi Hojo MD tahojo@east.ncc.go.jp
A confirmation study of omitting axillary dissection in patients with breast cancer and positive sentinel nodes

Norie Jibiki¹, Akira Hirano², Tetsuya Ochi³, Akiko Sakamoto⁴, Kiyomi Horiuchi⁵, Eichiro Noguchi⁶, Yoko Omi⁷, Kaoru Ogura⁸, Hiroaki Inoue², Takako Kamio³, Yoshihiko Naritaka², Mariko Fujibayashi², Kenzo Hiroshima¹, Yoji Nagashima³, Shuji Sakai³, Kumiko Karasawa³ and Takahiro Okamoto³. ¹Tokyo Women's Medical University Yachiyo Medical Center, Yachiyo, Japan; ²Tokyo Women's Medical University Medical Center East, Tokyo, Japan and ³Tokyo Women's Medical University Hospital, Tokyo, Japan.

Background
The omission of axillary dissection for positive sentinel-node breast cancer is considered the standard treatment for patients who undergo breast conserving surgery and radiation therapy, according to the results of ACOSOG-Z0011 and AMAROS trials. On the other hand, some surgeons still think that the surgical stress of axillary dissection is minimal, and dissection is permitted. Furthermore, Z0011 contains several problems, such as insufficient number of entry cases and lack of radiation field unity. Thus, we planned a prospective trial to confirm the safety of omitting axillary dissection in patients with breast cancer and positive sentinel nodes.

Trial design
This is a single arm, confirmation study of three medical centers. Prior to surgery, informed consent is obtained, and patients are registered primarily. After surgery, patients with 1 to 2 positive sentinel nodes, for whom axillary dissection was omitted, are finally included in this trial at final registration.

Eligibility criteria
Patients with histologically-diagnosed breast cancer, Tis–2, N0 based on a core needle biopsy, will be included in this trial. Eligible patients must be between 20 and 80 years of age, with a performance status of 0–2 and adequate organ function. They must not have undergone any prior operation, radiation therapy, chemotherapy, endocrine therapy, or immunotherapy.

Specific aims
The primary endpoint is 5-year (y) axillary recurrence rate. Secondary endpoints are 5-y overall survival, 5-y recurrence-free survival, 5-y local recurrence-free survival, the rate of upper-limb lymphedema, quality of life, and comparison of axillary recurrence rates between patients with two or more dissected nodes and those with only one positive node.

Statistical methods
The expected rate of axillary recurrence is 2.0%, and non-inferiority is defined as an axillary recurrence lesser than or equal to 5% in the axillary radiotherapy group. The sample size was calculated with a study power of 80% and type I error of 10% (two-sided). The required number of patients is estimated to be 189.

Present and target accrual
Patient accrual from the three medical centers was initiated in July 2016. We plan to enroll a total of 189 patients at final registration in this trial.
Multicenter study to standardize and evaluate the efficacy of radiofrequency ablation therapy for early breast cancer (RAFAELO study)

Takayuki Kinosita¹, Masato Takahashi², Tomomi Fujisawa³, Naohito Yamamoto⁴, Hiroyoshi Doihara⁵, Shoichiro Ohtani⁶, Manabu Futamura⁷, Mina Takahashi⁷, Kenjiro Aogi⁸, Takashi Hojo⁹, Masayuki Yoshida¹, Sho Shiino¹ and Hitoshi Tsuda¹⁰. ¹National Cancer Center Hospital, Tokyo, Japan; ²Hokkaido Cancer Center, Sapporo, Japan; ³Gunma Prefectural Cancer Center, Ohta, Japan; ⁴Chiba Cancer Center, Chiba, Japan; ⁵Okayama University Hospital, Okayama, Japan; ⁶Hiroshima City Hiroshima Citizens Hospital, Hiroshima, Japan; ⁷Gifu University Hospital, Gifu, Japan; ⁸Shikoku Cancer Center, Matsuyama, Japan; ⁹National Cancer Center Hospital, East, Kashiwa, Japan and ¹⁰National Defence Medical College, Tokorozawa, Japan.

**Background:** Early-stage breast cancer is increasingly detected by screening mammography, and we aim to establish radiofrequency ablation therapy (RFA) as a minimally invasive, cost-efficient, and cosmetically acceptable local treatment. In our Phase I study, localized tumors with a maximum diameter of 2 cm, preoperatively diagnosed by imaging and histopathology, were treated with RFA. A 90% complete ablation rate was confirmed histopathologically. Our phase II multicenter study of RFA without resection for early breast cancer will evaluate the long-term safety and efficacy of RFA as well as its cosmetic results, which are a perceived advantage of this technique.

**Trial design:** This study is a Phase III, single-arm, multicenter study being conducted with the participation of 11 hospitals. In our experimental therapy, a radiofrequency electrode needle is inserted through the skin into the breast lesion under imaging guidance, followed by thermal ablation with radiofrequency waves. RFA will be conducted under general anesthesia. The Cool-tip™ RF Ablation Single Electrode Kit (Medtronic, CO, USA) will be used to standardize the evaluation of the ablation effect. After RFA, all patients will receive radiotherapy and systemic therapy according to the ER, HER2, tumor grade, and lymph node status of the primary tumor. Residual lesions after RFA will be assessed approximately 3 months after radiotherapy using imaging and pathological studies. All patients will undergo vacuum-assisted biopsy regardless of imaging results. If specimens show viable tumor tissue, additional excision will be performed. Follow-up evaluation for residual tumor, including clinical breast examination and diagnostic imaging (ultrasound, MRI, and mammography), will be performed yearly after RFA. This trial has been registered at the UMIN Clinical Trials Registry as UMIN000012429.

**Eligibility criteria:** Early breast cancer patients, who are lack of prior treatment for breast cancer and histologically confirmed ductal carcinoma with a single localized tumor of 1.5 cm or less in the greatest dimension and clinically node negative on preoperative imaging.

**Specific Aims:** The primary endpoint is 5-year ipsilateral breast tumor recurrence (IBTR) rate, and the secondary endpoints are residual lesion rate, overall survival, DFS, and adverse events of RFA.

**Statistical methods:** The IBTR rate should be similar to that with standard treatment (BCS). However, the IBTR after RFA alone may be higher by up to 10% than in the NSABP-B06 study; therefore the 5-year IBTR rate is estimated to be 6.3%. We calculated the required sample size based on the following assumptions: a clinically acceptable 5-year local recurrence-free survival rate of 90%, a one-sided significance level of 5% (alpha = 0.1, 2-sided), and power of 80% (beta = 0.2). Taking into account a drop-out rate of 10%, approximately 372 patients will be enrolled in the study.

**Present accrual and target accrual:** The trial was activated in August 2013, with a total of 372 patients enrolled by the end of June 2018.
Phase III trial to determine if chest wall and regional nodal radiotherapy (CWRNRT) post mastectomy (Mx) or the addition of RNRT to whole breast RT post breast-conserving surgery (BCS) reduces invasive breast cancer recurrence-free interval (IBCR-FI) in patients (pts) with pathologically positive axillary (PPAx) nodes who are ypN0 after neoadjuvant chemotherapy (NC):

NRG Oncology/NSABP B-51/RTOG 1304

Eleftherios P Mamounas¹,²,³, Hanna Bandos¹,²,⁴, Julia R White¹,⁵, Thomas B Julian¹,²,⁶, Atif J Khan¹,⁷, Simona F Shaitelman¹,⁸, Mylin A Torres¹,⁹, Frank A Vicini¹,₁₀, Patricia A Ganz¹,₁¹, Susan A McCloskey¹,₁¹, Soonmyung Paik¹,²,₁², Nilendu Gupta¹,⁵, X Allen Li¹,₁³, Dominic J DiCostanzo¹,₁⁴, Walter J Curran¹,⁹ and Norman Wolmark¹,²,⁶. ¹NRG Oncology, Pittsburgh, PA; ²NRG Oncology/NSABP, Pittsburgh, PA; ³Orlando Health UF Health Cancer Center, Orlando, FL; ⁴University of Pittsburgh, Pittsburgh, PA; ⁵Ohio State University, Columbus, OH; ⁶Allegheny Cancer Center at Allegheny General Hospital, Pittsburgh, PA; ⁷Memorial Sloan Kettering Cancer Center, New York, NY; ⁸University of Texas MD Anderson Cancer Center, Houston, TX; ⁹Winship Cancer Institute at Emory University School of Medicine, Atlanta, GA; ¹⁰MPH Radiation Oncology Institute St. Joseph Mercy Hospital Campus, Pontiac, MI; ¹¹University of California, Santa Monica, CA; ¹²Yonsei University College of Medicine, Seoul, Korea and ¹³Medical College of Wisconsin, Milwaukee, WI.

This phase III post-NC trial evaluates if CWRNRT post-Mx or whole breast irradiation (WBI) with RNRT after BCS significantly reduces the IBCR-FI rate in pts with PPAx nodes that are pathologically negative after NC. Secondary aims are OS, LRR-FI, DR-FI, DFS-DCIS, second primary cancer, and comparison of RT effect on cosmesis in reconstructed Mx pts. Correlative science examines RT effect by tumor subtype, molecular outcome predictors for residual disease, and predictors for the degree of reduction in loco-regional recurrence.

**Methods:** Clinical T1-3, N1 IBC PPAx nodes (FNA or core needle biopsy) pts complete ≥8 weeks of NC (anthracycline and/or taxane). HER2+ pts receive anti-HER2 therapy. Following NC, BCS or Mx, sentinel node biopsy (≥2 nodes) and/or Ax dissection with histologically negative nodes is performed. ER/PR and HER-2neu status before NC is required. Pts may receive appropriate adjuvant systemic therapy. Radiation credentialing with a facility questionnaire/case benchmark is required. Random assignment for Mx pts is to no CWRNRT or CWRNRT and for BCS pts to WBI or WBI+RNRT.

**Statistics:** 1,636 pts are to be enrolled over 5 yrs (definitive analysis at 7.5 yrs). Study is powered at 80% to test that RT reduces the annual hazard rate of events for IBCR-FI by 35% for an absolute risk reduction of 4.6% (5-yr cumulative rate). Intent-to-treat analysis with 3 interim analyses (43, 86, and 129 events) and a 4th/final analysis at 172 events. Pt-reported outcomes focusing on RT effect will be provided by 736 pts before random assignment and at 3, 6, 12, and 24 mos. Accrual as of 6-21-18 is 967 (59.11%).

Background
In patients with early stage breast cancer, regional nodal irradiation (RNI) is added to whole breast irradiation (WBI) in order to control microscopic regional disease and to prevent systemic spread of cancer. According to recent randomized trials (MA.20 and EORTC 22922-10925), prophylactic RNI was associated with improvement in disease-free survival (DFS) in the patients with high-risk node negative or pN1 breast cancer. However, systemic agents now known to improve loco-regional control, such as taxane or endocrine therapy, were prescribed to a small percentage of patients in the studies. The benefit of RNI found in the previous studies might be attributed to incorporation of less effective systemic treatments. The impact of prophylactic RNI in pN1 breast cancer should be evaluated in the patients receiving modern systemic treatment. The current study was conducted to compare the effect of post-lumpectomy WBI vs WBI plus RNI on DFS in pN1 breast cancer patients who received adjuvant taxane-based chemotherapy.

Methods
This study is a multicenter, phase 3, randomized controlled non-inferiority trial (NCT03269981). Eligibility criteria are ≥ 20 years female; pathologically proven invasive carcinoma of the breast; one to three positive axillary lymph nodes (pN1) in pathologic specimen; receiving breast-conserving surgery followed by taxane-based chemotherapy; having adjuvant endocrine therapy or anti-HER2 treatment according to molecular subtype of tumor. Patients are randomly assigned in a 1:1 ratio to receive WBI or WBI plus RNI. Patient randomization was stratified by molecular subtype of tumor (i.e. luminal A/luminal B/luminal HER2/HER2-enriched/triple-negative) and methods of axillary management (i.e. sentinel lymph node biopsy/axillary lymph node dissection). The primary outcome is DFS. The secondary outcomes include DFS according to molecular subtype, treatment-related toxicity, and patient's quality of life per EORTC QLQ-C30 and QLQ-BR23. Patients will be followed for survival and disease recurrence for seven years. A total of 1,926 patients are planned to be enrolled, with recruitment initiated in April 2017. As of June 2018, a total of 236 patients were enrolled.

This study was supported by a grant from the National R&D Program for Cancer Control, Ministry of Health & Welfare, Republic of Korea (grant number: HA17C0043010018).
Examining personalized radiation therapy (EXPERT): A randomised phase III trial of adjuvant radiotherapy vs observation in patients with molecularly characterized luminal A breast cancer

Boon H Chua¹,², Kathryn Gray², Meinir Krishnasamy¹⁰, Meredith Regan², Nicholas Zdenkowski³, Sherene Loi³, Bruce Mann¹¹, John F Forbes⁴, Nicholas Wicken⁵, Andrew Spillane³, Andrew Martin⁴, Heath Badger⁶, Syed Jafari⁵, Akiko Fong⁵, Carlie Mavin⁵, Sabine Corachan⁵, Amal Arahmani⁵, Jorge-Luis Martinez⁵ and Prudence Francis³. ¹Prince of Wales Hospital, Randwick, NSW, Australia; ²Dana-Farber Cancer Institute, Boston, MA; ³Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; ⁴The University of Sydney, Sydney, NSW, Australia; ⁵Breast Cancer Trials, Newcastle, NSW, Australia; ⁶Westmead Hospital, Sydney, NSW, Australia; ⁷The Mater Hospital, Sydney, NSW, Australia; ⁸Breast International Group, Brussels, Belgium; ⁹University of New South Wales, Sydney, NSW, Australia; ¹⁰University of Melbourne, Melbourne, VIC, Australia and ¹¹Victorian Comprehensive Cancer Centre, Melbourne, VIC, Australia.

Background
Radiation therapy (RT) after breast conserving surgery (BCS) is the current standard of care for patients with early stage breast cancer. However, individual absolute recurrence risks and hence benefits of RT vary substantially. A study showed significant association between local recurrence (LR) risk and PAM50-defined intrinsic subtypes and Risk of Recurrence scores (ROR).¹ The objective of EXPERT, a co-lead study of Breast Cancer Trials-Australia & New Zealand (BCT-ANZ), and Breast International Group (BIG), is to optimize local therapy for early breast cancer through precise individualized quantification of LR risk to identify patients for whom RT after BCS may be safely omitted.

Trial design
This is a randomized, non-inferiority, phase III study of women who plan to receive adjuvant endocrine therapy for Prosigna (PAM50)-defined luminal A breast cancer with ROR ≤60 resected by BCS. Women are randomized to receive adjuvant whole breast RT and endocrine therapy or endocrine therapy alone and followed-up for 10 years after randomization.

Major eligibility criteria
Females aged ≥50 years; histologically confirmed invasive breast carcinoma ≤2 cm, grade 1 or 2, ER and PgR ≥10%, HER2-negative and node-negative; treated by BCS with negative margins for invasive carcinoma and associated DCIS; Prosigna (PAM50)-defined Luminal A subtype and ROR ≤60; and plan to receive adjuvant endocrine therapy.

Specific aims
Primary: To determine if omission of RT is not inferior to RT in terms of LR-free interval after BCS.
Secondary: To evaluate the impact of omission of RT on regional, local-regional and distant recurrence-free interval; disease-free survival (DFS); invasive DFS; overall survival; salvage RT or mastectomy rate; toxicity; endocrine therapy adherence; patient reported outcomes; and health economic outcomes.

Statistical methods
An estimated 5-year LR rate in the target population is expected to be 1% with RT. A rate of 4% is considered non-inferior as a worthwhile trade-off against RT toxicity. Using O'Brien-Fleming boundary for rejecting non-inferiority, 29 LR events are required for final analysis expected 8 years after the first patient is randomized. Two interim analyses will be conducted after 10 and 21 events. If the stratified log-rank test statistic exceeds the upper boundary at interim or final analysis, the hypothesis of non-inferiority will be rejected and it will be concluded that no RT is inferior to RT.

Accrual: Target (1170), actual: 82 (June 2018)
The study was activated in Australia in August 2017, with global activation planned for Q4 2018. Recruitment is expected to be completed in 4.5 years.

Multi-institution phase II trial of intraoperative electron beam radiotherapy boost at the time of breast conserving surgery with oncoplastic reconstruction in women with early-stage breast cancer

Jose G Bazan¹, Julie Stephens¹, Doreen Agnese¹, Roman Skoracki¹, Kyle Arneson², Julie Reiland², Gaorav Gupta³, Kristalyn Gallagher³, Sohyun McElroy¹, Nilendu Gupta¹ and Julia R White¹. ¹The Ohio State University, Columbus, OH; ²Avera Medical Group, Sioux Falls, SD and ³University of North Carolina-Chapel Hill, Chapel Hill, NC.

Background: In women amenable to breast conserving therapy, lumpectomy followed by adjuvant whole breast irradiation (WBI) remains the standard of care. Randomized trials demonstrate that addition of a lumpectomy cavity boost significantly reduces the risk of ipsilateral breast tumor recurrences but also increases the risk of breast fibrosis. Contemporary randomized trials define the lumpectomy cavity boost volume as a 1.7 cm isometric expansion on the lumpectomy cavity as delineated on CT. However, identifying the lumpectomy cavity can be challenging, especially in women that receive adjuvant chemotherapy and in cases in which surgical clips are not present. Recently, the use of oncoplastic techniques in breast conserving surgery has increased. These techniques are used to prevent the poor cosmetic results that can occur when a large volume of breast tissue is resected. Women that undergo oncoplastic reconstruction represent especially difficult cases for lumpectomy cavity delineation. Retrospective series have evaluated the use of intraoperative electron radiotherapy (IOERT) as a boost prior to WBI in women receiving lumpectomy without oncoplastic reconstruction. In the largest series of IOERT boost prior to WBI the local control rate of this approach was >99%. Prospective data regarding IOERT boost in women undergoing oncoplastic reconstruction are limited. The advantages of this approach include direct visualization/irradiation of the tumor bed, sparing the skin of irradiation, and reducing the treatment time by ~1 week. We hypothesize that IOERT boost followed by WBI will result in acceptably low rates of grade 3 fibrosis in women undergoing lumpectomy with oncoplastic reconstruction.

Trial Design: This is a single-arm, prospective study to evaluate the safety, toxicity and efficacy of IOERT boost at the time of breast conserving surgery in women with early-stage breast cancer undergoing oncoplastic reconstruction. Eligible women will receive 1 dose of 8 Gy to the surgical bed after lumpectomy but prior to oncoplastic reconstruction. Women will then receive adjuvant WBI of 40 Gy in 15 fractions or 50 Gy in 25 fractions.

Eligibility: Key criteria include age≥18 yo, clinically node-negative stage I/II, any breast cancer subtype.

Specific Aims: To determine the rate of grade 3 breast fibrosis at 1 year. Additional aims include surgical complication rates, cosmesis, and local regional cancer control.

Statistical Methods: Safety will be evaluated by the rate of surgical complications necessitating hospital readmission or return to the operating room within 30 days of surgery+IOERT. If ≥4 events in the first 10 patients, ≥7 events in the first 20 patients, or ≥9 events in the first 30 patients are seen, the study will be halted. We hypothesize that the grade 3 fibrosis rate in our study will be ≤5%. Assuming an actual rate of 4%, an unacceptable rate of 9%, and a drop-out rate of 10%, the expected sample size is 176.

Sites: Ohio State University, Avera Medical Group, University of North Carolina-Chapel Hill

Patient Accrual: Current accrual is 5/176.

Phase II trial of pre-operative stereotactic ablative radiotherapy (SABR) in early-stage breast cancer

Casey L Liveringhouse, Roberto Diaz, Kamran A Ahmed, Marie C Lee, Brian Czerniecki, Christine Laronga, Nazanin Khakpour, Robert J Weinfurtner, Marilin Rosa and Michael E Montejo. 1University of South Florida College of Medicine, Tampa, FL and 2H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL.

Background:
Post-operative accelerated partial breast irradiation (APBI) has demonstrated efficacy in preventing in-breast tumor recurrence. Pre-operative administration of APBI may be advantageous as an intact breast tumor is smaller than its corresponding lumpectomy cavity, is easier to distinguish on treatment-planning images, and results in smaller and more accurately delineated target volumes. Pre-operative APBI may reduce the incidence of positive margins following breast-conserving surgery (BCS). Investigation is needed in the correlation of MR imaging with pathologic response 6 weeks after SABR. Also, evidence suggests that SABR induces immune activation in the tumor microenvironment; evaluation of excised tumor tissue will give insight into these processes.

Trial Design:
Treatment Planning and Delivery: CT simulation and treatment are performed in the prone position. Diagnostic MRI is fused to planning CT. GTV is delineated on registered breast MRI and includes the intact breast tumor. CTV is 15mm expansion of GTV. PTV is 3 mm expansion of CTV. VMAT or IMRT are permitted. Daily image-guidance aligning to tumor and biopsy-fiduccial is mandatory. All subjects undergo pre-operative SABR to 28.5 Gy in 3 fractions of 9.5 Gy on different days separated by ≤48 hours. CTCAE v4 is used to assess toxicity 4-5 weeks after SABR. Pre-operative diagnostic MRI is performed 5-6 weeks following SABR. Imaging parameters to be evaluated include changes in tumor size, enhancement, and tumor margin description. BCS will be 6-8 weeks following SABR. Tissue pathology: Margin status and degree of pathologic response are recorded from breast-conserving excisions, specimens are archived for future analysis.

Eligibility Criteria:
Inclusion criteria are women age ≥50 with biopsy proven invasive breast adenocarcinoma with tumor size ≤2cm on MRI, cN0 M0, ER+/HER2-, without history of invasive malignancy or prior breast/thoracic radiotherapy. Exclusion criteria are active scleroderma or lupus erythematosus with skin involvement, MRI defined tumor within 10 mm of skin, implanted hardware prohibiting appropriate treatment planning or delivery, neoadjuvant chemotherapy, carrier of BRCA1 or 2 gene mutation, pregnancy.

Specific Aims:
The primary endpoint is pathologic complete response (pCR) in the breast tumor, secondary endpoints are incidence of adequate surgical margins (defined as “no tumor on ink”) and MRI response following SABR. Analyses of tumor immune response and microenvironment on pathologic specimens following SABR will also be performed.

Statistical Methods:
Fisher’s exact test will be performed to examine associations between patient/tumor characteristics and pCR and surgical margins; these associations will be explored with multivariable logistic and linear regressions.

Accrual:
Present accrual is 9 subjects. Expected accrual is 22 subjects; if ≥3 pCR are noted in the initial cohort, accrual will be expanded to 40 subjects.
FAMILY: A randomized, multicenter, open-label, phase III trial of fulvestrant versus capecitabine as maintenance therapy after first-line combination chemotherapy in patients with hormone receptor-positive, human epidermal growth factor receptor-2 negative metastatic breast cancer

Herui Yao¹, Wenjing Wu¹, Linxiaoxiao Ding¹, Yunfang Yu¹, Ying Wang¹, Yinduo Zeng¹, Jianli Zhao¹ and Qingjian Li². ¹Breast Tumor Center, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China and ²Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China.

Background: Metastatic breast cancer (MBC) is incurable. Although first-line endocrine therapy is preferred to hormone receptor positive (HR+), human epidermal growth factor receptor-2 negative (HER2-) MBC, combination chemotherapy should be reserved as the initial treatment for patients with rapid clinical progression, life-threatening visceral metastases, and need for rapidly symptom control. Either prolonged chemotherapy or endocrine therapy may be used as maintenance after disease control. However, which maintenance strategy is superior in terms of delaying disease progression as well as maintaining quality of life (QOL) remains uncertain. This phase III trial aims to compare the efficacy and safety of fulvestrant or capecitabine as maintenance therapy after first-line combined chemotherapy in HR+/HER2- MBC.

Trial Design: FAMILY is a multicenter, randomized, open-label phase III trial for HR+ and HER2- MBC. Eligible participants are randomized (1:1) to receive capecitabine (2000mg/m2 twice daily x 14 days followed by 7 days off) or fulvestrant (500mg Days 0, 14, 28, then every 28 days) until disease progression, unacceptable toxicity, or patient refusal. Stratification factor for randomization is sensitivity to adjuvant hormonal therapy (disease-free interval ≤24 months vs. >24 months).

Eligibility Criteria: Eligible patients must have HR+ (ER and/or PR>1%, by IHC) and HER2- MBC; achieved a complete or partial response or stable disease (investigator assessed) after 4-8 cycles of first-line combination chemotherapy. Patients with central nervous system metastasis and/or prior use of endocrine therapy for advanced breast cancer are excluded.

Specific Aims: The primary endpoint is progression free survival (PFS). Secondary endpoints include overall survival, overall response rate, disease control rate, safety and QOL. A prospective translational research is also planned to assess the correlations between biomarkers and response.

Statistical Design: The planned sample size of 256 patients provides approximately 80% of power to detect a 6 months difference of PFS using a log-rank test with two-sided alpha of 0.05.

Target Accrual: Recruitment is ongoing. Up to 256 evaluable subjects will be enrolled within 24 months. (ChiCTR-IIR-17014036).
Breast cancer (BC) is so-called “systemic disease”, because disseminated cancer cells in bone marrow and blood are detected even in early BC patients. Despite adjuvant therapy and postoperative radiation therapy, patients with triple negative BC and Luminal B-like BC often relapse early and systemic therapy is the only way to control disease progression. On the other hand, some BC patients relapse several years later. In such patients, oligometastases are occasionally diagnosed, because metastatic cancer cells are slowly growing and indolent. Oligometastatic BC is defined as low volume metastatic disease with limited number and size of metastatic lesions (up to five and not necessarily in the same organ). This definition is proposed in the Advanced Breast Cancer guidelines that are developed as a joint effort from European School of Oncology and European Society of Medical Oncology. Several retrospective studies demonstrated survival benefit of locoregional therapy in addition to systemic therapy. Locoregional therapy consisted of surgical resection, radiation therapy, ablation therapy, etc. However, it remains unclear about survival benefit of combined therapy in oligometastatic BC. To improve the standard of cancer treatment through the cooperate studies on more effective therapeutic strategies based on drugs, surgery and/or radiotherapy, Federation of Asian Clinical Oncology (FACO) was established in 2012 by Chinese Society of Clinical Oncology (CSCO), Korean Society of Medical Oncology (KSMO) and Japan Society of Clinical Oncology (JSCO). Thus, FACO conducted a retrospective cohort study on oligometastatic BC. The primary endpoint is to compare the estimated 5-year overall survival (OS) of oligometastatic BC patients treated with combined therapy and systemic therapy alone. To hypothesize that combined therapy has more advantage of OS in oligometastatic BC, the 5-year OS rates are expected to be 50% and 40%, respectively. The estimated sample size is calculated to be the number of 698 cases (349 cases in each group) needed to prove the superiority of survival with a two-sided type I error rate of 5% and a statistical power of 80%. Case registry opened in February 2018 and will close in January 2019. We planned to register 700 cases, i.e., 234 cases each from investigators of CSCO, KSMO and JSCO. Update information will be discussed.
Highly innovative personalized RNA-immunotherapy for patients with triple negative breast cancer

Marcus Schmidt¹, Stefanie Bolte², Katrin Frenzel², Ludwig Heesen², Evelyna Derhovanessian², Valesca Bukur²,³, Mustafa Diken²,³, Jan Gruetzner², Sebastian Kreiter²,³, Alina Klein², Andreas Kuhn², David Langer², Martin Loewer³, Henrik Lindman⁴, Andreas Schneeweiss⁵, Oezlem Tuereci² and Ugur Sahin². ¹Klinik und Poliklinik für Geburtshilfe und Frauengesundheit, Universitätsmedizin Mainz, Mainz, Germany; ²Biopharmaceutical New Technologies (BioNTech) Corporation, Mainz, Germany; ³TRON gGmbH, Mainz, Germany; ⁴Uppsala University Hospital, Uppsala, Sweden and ⁵Sektion Gynäkologische Onkologie, NCT Heidelberg, Heidelberg, Germany.

Background: The treatment of triple negative breast cancer (TNBC) is hampered by the lack of established therapeutic targets such as hormone receptors or HER-2. Chemotherapy and radiotherapy is the standard of care, yet survival rates in TNBC remain poor. Approaches tailored to the patient's individual tumor signature may lead to improved therapeutic outcome. We have set up a clinical workflow covering drug development (from target discovery to manufacturing) and drug release providing a custom-made investigational medicinal product (IMP) for each individual patient.

Trial Design: A phase I/II trial assesses the feasibility, safety and biological efficacy of this personalized immunotherapy in three clinical sites in Germany and Sweden. TNBC patients (pT1cN0M0 – T NxN xM0) after completion of initial standard of care therapy will be allocated to one of two study arms. Patients in ARM1 receive 8 vaccination cycles with a personalized combination of shared tumor-associated antigens, selected based on each patient tumor's antigen-expression profile out of a WAREHOUSE of pre-manufactured mRNA vaccine. Patients in ARM2 receive the personalized mRNA WAREHOUSE vaccine followed by 8 vaccination cycles of an on-demand manufactured mRNA MUTANOME vaccine encoding up to twenty unique neo-epitopes of the individual patient identified by next generation sequencing. The mRNAs are administered intravenously as a nanoparticulate lipoplex formulation, which protects RNA from degradation, activates innate immunity, transfects APCs and consequently induces highly potent antigen-specific T-cell responses. The treatment of 12 patients in ARM1 is completed and enrolment of patients for ARM2 has started. Preliminary data show that the RNA-WAREHOUSE approach is feasible and can be applied safely. Biomarker analysis is ongoing. This approach is promising as it addresses the heterogeneity of TNBC.

The TNBC-MERIT trial was initially funded by the EU Commission's FP7 and led by BioNTech AG.
Chemokine modulation to enhance the effectiveness of pembrolizumab in patients with metastatic triple negative breast cancer

Yara Abdou¹, Lauren E Williams¹, Pawel Kalinski¹ and Mateusz Opyrchal¹. ¹Roswell Park Comprehensive Cancer Center, Buffalo, NY.

**Background:** Triple negative breast cancer (TNBC) is found in approximately 15-20% of all breast cancer, and is associated with poor prognosis, early relapse and a significantly shorter survival following recurrence. Early phase trials with immune checkpoint inhibitors have shown modest yet durable clinical responses with a tolerable safety profile. Strategies to sensitize these tumors to checkpoint inhibition will result in decreased morbidity and mortality.

Tumor infiltrating immune cells and intratumoral expression of PD-1/PD-L1/PD-L2 can predict patients' benefit from Pembrolizumab. Pre-clinical *ex-vivo* data show that chemokine modulating regimen consisting of Rintatolimod, IFNα and COX2 blocker (CKM), selectively attracts cytotoxic T cells into tumors, and increases intratumoral expression of PD-1/PD-L1/PD-L2, without enhancing soluble suppressive mechanisms. Furthermore, mouse data has shown safety of CKM and PD-1 blockade combination and efficacy in inducing long-term survival of mice with resistant tumors.

Clinical trials of CKM in Colon and ovarian cancer (NCT01545141, NCT02432378) demonstrated safety of Rintatolimod given with IFNα/COX2, and preliminary data show local efficacy in tumor microenvironment modulation.

**Design:** This is an open-label, single center, phase Ila study to test Chemokine modulating regimen (CKM) pre-treatment followed by Pembrolizumab in patients with metastatic TNBC, regardless of PD-1 expression, who progressed on ≥1 lines of therapy.

Patients are given pre-treatment CKM, which consists of Rintatolimod (200 mg IV), IFNα-2 (20 million units/m² IV) and Celecoxib (200 mg po BID), on 3 consecutive days for a total of 2 cycles, one week apart. The patient is then treated with Pembrolizumab 200 mg IV every 3 weeks until disease progression, intolerable side effects or withdrawal from study for up to 24 months. Study includes pre- and post CKM treatment biopsies.

**Eligibility:** Major criteria include age ≥ 18 years, ECOG ≤ 1, histologically proven metastatic TNBC, normal organ and marrow function, no active autoimmune disease or history of transplant, no prior anti-PD1/PDL1 therapy.

**Aims:** Primary objective is to evaluate the overall response rate to the combination therapy per irRECIST criteria. Secondary objectives include safety profile of the combination therapy, determining progression free survival, overall survival and disease control rate. Other immune exploratory objectives will include baseline and CKM-induced predictive biomarkers of clinical activity of the combination treatment.

**Statistical Methods:** The study includes a safety lead-in of 6 patients and utilizes a Simon two-stage minimax design. 18 patients are enrolled into stage 1 of the study. If < 4 responses are observed, the treatment combination will not be considered promising and enrollment will be terminated. However, if ≥ 4 responses are observed, then an additional 19 patients will be enrolled into stage 2, for a total number of 37 patients. In stage 2, if ≥ 9 responses are observed, then the treatment combination will be considered promising for future study.
A phase 2 study of intratumoral tavokinogene telseplasmid (tavo) plus electroporation with pembrolizumab in patients with inoperable locally advanced or metastatic triple negative breast cancer

Melinda L Telli1, Irene Wapnir1, Shaveta Vinayak2, Jenny Chang3, Carlos Alemany4, Chris Twitty5 and Sharron Gargosky5.
1Stanford University Medical Center, Stanford, CA; 2University of Washington, Seattle, WA; 3Houston Methodist Cancer Center, Houston, TX; 4Florida Hospital Cancer Institute, Orlando, FL and 5OncoSec Medical, San Diego, CA.

Triple negative breast cancer (TNBC) accounts for 10-20% of breast cancer diagnoses and is associated with a high risk of recurrence and a more aggressive course in the metastatic setting. Emerging data suggest that some patients with TNBC could benefit from the addition of immune-based therapy due to the important role of tumor infiltrating lymphocytes (TILs) on outcome. Reports show that early-stage TNBC patients with at least 50% TILs demonstrate longer disease-free survival. Additionally, immune-modulating therapies, like the anti-PD-1/PD-L1 monoclonal antibodies, have demonstrated modest activity in the pre-treated metastatic TNBC population with objective response rates (ORR) <10%, but appear to require an immunogenic tumor, characterized by CD8+ TILs, in order to be effective. Plasmid IL-12 (tavo) with electroporation (tavo-EP) is a gene therapy approach yielding sustained intratumoral expression of the proinflammatory cytokine IL-12. Combining tavo-EP with an anti-PD-1 therapy, such as pembrolizumab, may improve responses for TNBC subjects by potentially converting poorly-immunogenic/low TIL tumors into high TIL/immune-responsive tumors while providing a favorable side-effect profile. OMS-I141 is a phase 2, non-randomized, study of intratumoral tavo-EP with pembrolizumab in patients with locally-advanced, inoperable, metastatic and/or treatment-refractory TNBC. Key inclusion criteria include documented inoperable locally advanced or metastatic TNBC, at least 1 prior line of approved systemic chemotherapy or immunotherapy and an accessible lesion for intratumoral injection and electroporation. Eligible subjects will receive intratumoral tavo-EP to the accessible lesions on Days 1, 5 and 8 every 6 weeks and intravenous (IV) pembrolizumab (200 mg) on Day 1 of each 3-week cycle. The primary objective of the study is to assess the ORR by blinded independent central review based on RECIST v 1.1. Secondary objectives include assessment of safety and tolerability of the combined treatment, duration of response (DOR), ORR (investigator-assessed), immune ORR (iORR), progression-free survival (PFS), immune PFS (iPFS) and overall survival (OS). A Simon 2-Stage design will be employed and a total of 25 patients will be accrued. In Stage 1 up to 15 subjects will be enrolled. If the number of responders meet the pre-specified number (N ≥ 1/15), then the enrollment for Stage 2 will include an additional 10 subjects (for a total of ≥ 6 responders out of 25 subjects). For more information regarding the study, contact OncoSec at info@oncosec.com.
MORPHEUS: A phase Ib/II trial platform evaluating the safety and efficacy of multiple cancer immunotherapy combinations in patients with hormone receptor–positive and triple-negative breast cancer

Denise A Yardley¹, Maysa Abu-Khalaf², Valentina Boni³, Adam Brufsky⁴, Leisha A Emens⁵, Martin Gutierrez⁶, Sara Hurvitz⁷, Seock-Ah Im⁸, Sherene Loi⁹, Steven L McCune¹⁰, Peter Schmid¹¹, Carol O'Hear¹², Xiaosong Zhang¹² and Gregory A Vidal¹³.

¹Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN; ²Thomas Jefferson University Hospital, Philadelphia, PA; ³START Madrid, Centro Integral Oncológico Clara Campal (CIOCC), Madrid, Spain; ⁴Medical Oncology, Magee-Women's Hospital of UPMC, Pittsburgh, PA; ⁵Bloomberg–Kimmel Institute for Cancer Immunotherapy at Johns Hopkins, Baltimore, MD; ⁶Hackensack University Medical Center John Theurer Cancer Center, Hackensack, NJ; ⁷Geffen School of Medicine at UCLA, Los Angeles, CA; ⁸Seoul National University Hospital, Seoul, Korea; ⁹Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; ¹⁰Northwest Georgia Oncology Centers, Marietta, GA; ¹¹Barts Cancer Institute, Queen Mary University of London, London, United Kingdom; ¹²Genentech, Inc., South San Francisco, CA and ¹³University of Tennessee West Cancer Center, Germantown, TN.

Background:
Cancer immunotherapy (CIT) has significantly improved overall survival across multiple tumor types, but only subsets of patients experience durable response with single-agent CIT. Combinations of CIT with targeted therapy or chemotherapy may be needed in order to target multiple cancer immune escape mechanisms simultaneously, thus providing personalized treatment options that extend clinical benefit to more patients. The MORPHEUS platform includes multiple phase Ib/II trials designed to identify early signals of safety and activity of CIT combinations. Using a randomized trial design, multiple CIT combination arms are compared with a single standard-of-care control arm. These trials have the flexibility to open new treatment arms with novel CIT combinations as they become available and to close arms that show minimal activity or unacceptable toxicity. Here we describe MORPHEUS trials in patients with metastatic or unresectable locally advanced hormone receptor–positive (HR+BC) or triple-negative breast cancer (TNBC), 2 patient populations in need of more treatment options.

Trial design:
MORPHEUS-HR+BC (NCT03280563) will enroll patients with metastatic or unresectable locally advanced HR+BC who have progressed during or after first-line treatment with a cyclin-dependent kinase (CDK) 4/6 inhibitor and whose tumors do not express human epidermal growth factor 2 (HER2). MORPHEUS-TNBC (NCT03424005) will enroll patients with metastatic or unresectable locally advanced TNBC who have progressed during or after first-line treatment with chemotherapy. For both studies, key inclusion criteria include Eastern Cooperative Oncology Group performance status of 0-1 (stage 1) or 0-2 (stage 2) and measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Key exclusion criteria include prior treatment with T-cell co-stimulating or immune checkpoint blockade therapies, and symptomatic, untreated, or actively progressing central nervous system metastases. Patients in both trials will be randomized to one of the CIT atezolizumab combination arms or a control arm (up to 5 arms in HR+BC and up to 6 arms in TNBC). Patients experiencing loss of clinical benefit or unacceptable toxicity in stage 1 may be eligible to switch to a different CIT atezolizumab combination arm in stage 2. Primary endpoints are safety measures and investigator-assessed objective response rate per RECIST v1.1. Progression-free survival, overall survival, duration of response, clinical benefit rate (HR+BC) or disease control rate (TNBC) are among the secondary endpoints. Exploratory biomarkers will also be examined.
A randomized phase II study of peri-operative ipilimumab, nivolumab and cryoablation versus standard peri-operative care in women with residual triple negative early stage/resectable breast cancer after standard-of-care neoadjuvant chemotherapy

Heather L McArthur¹, Elizabeth A Comen², Stephen Solomon², Micaela Rodine², Christina DiLauro Abaya¹, Jorge Henrique S Leal¹, Sujata Patil² and Larry Norton². ¹Cedars-Sinai Medical Center, Los Angeles, CA; ²Memorial Sloan Kettering Cancer Center, New York, NY and ³CLION - CAM Group, Salvador, Bahia, Brazil.

Background: Triple negative breast cancer (TNBC) is a biologically distinct subtype with high risk of early relapse, particularly for patients who do not achieve a pathological complete response (pCR) after neoadjuvant chemotherapy (NAC), with an event free survival of < 60% at 3 years. Physical disruption of tumors with cryoablation (cryo) induces inflammation and releases antigens that can activate tumor-specific immune responses. In pre-clinical studies, the combination of cryo with checkpoint inhibition augmented tumor-specific immune responses and prevented cancer recurrence. In clinical studies, the combination of peri-operative ipilimumab (ipi)- +/- nivolumab (nivo)-mediated checkpoint blockade with cryo was safely administered in women with operable, early stage breast cancer and generated intra-tumoral and systemic immune responses (NCT01502592, NCT02833233). In this multi-center, randomized study, we evaluate the disease specific impact of peri-operative ipi, nivo and cryo versus standard care in women with residual TNBC after neoadjuvant taxane-based chemotherapy (NCT03546686).

Methods: Eligible pts are aged ≥18 years, with ER, PR and HER2 negative operable tumors ≥ 1.0 cm after neoadjuvant taxane-based chemotherapy. Approximately 160 patients will be randomized to one of two arms: standard-of-care breast surgery (control arm) or ipi/nivo/cryo followed by standard-of-care breast surgery (intervention arm). Subjects randomized to the intervention arm will undergo percutaneous, ultrasound- (or MRI-) guided cryoablation with concurrent research core biopsy 7-10 days prior to surgery, and will receive a pre-operative infusion with ipilimumab at the dose of 1mg/kg IV, and nivolumab 240mg flat dose IV (1 to 5 days prior to cryoablation). After surgery, patients will receive three additional doses of nivolumab 240mg flat dose IV Q2 weeks. Adjuvant capecitabine is recommended for all participants and will be administered per standard-of-care at the treating physician's discretion. Patients will be stratified by prior platinum administration, prior anthracycline administration, and clinical nodal status (positive versus negative) at enrollment. The primary endpoint is 3-year Event Free Survival (EFS). Secondary end points include Invasive Disease-Free Survival (IDFS), Distant Disease-Free Survival (DDFS), overall survival (OS) and safety. Exploratory correlative studies will be performed on tumor and serum to characterize the immunologic impact of the intervention and to explore predictors of efficacy and toxicity.
DETECT V/CHEVENDO – Comparison of dual HER2-targeted therapy with trastuzumab plus pertuzumab in combination with chemo- or endocrine therapy in addition with CDK4/6 inhibition in patients with HER2-positive and hormone-receptor positive metastatic breast cancer

Sabrina Krause¹, Thomas Friedl¹, Tanja Fehm², Tatiana Romashova¹, Peter A Fasching³, Andreas Schneeweiss⁴, Volkmar Müller⁵, Florin-Andrei Taran⁶, Arkadius Polasik¹, Marie Tzschaschel¹, Amelie De Gregorio¹, Franziska Meier-Stiegen², Wolfgang Janni⁷ and Jens Huober¹. ¹University Hospital Ulm, Ulm, Germany; ²Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany; ³University Hospital Erlangen, Erlangen, Germany; ⁴National Center for Tumor Diseases and University Hospital Heidelberg, Heidelberg, Germany; ⁵University Hospital Hamburg-Eppendorf, Hamburg, Germany and ⁶University Hospital Tübingen, Tübingen, Germany.

Background:
Metastatic breast cancer (MBC) is usually an incurable disease and maintenance of quality of life (QoL) is one of the main aims of therapy. In patients with HER2-positive MBC taxane-based chemotherapy in combination with dual HER2 targeted therapy with trastuzumab and pertuzumab, is the standard of care. Adverse events are well-known side effects of any cytostatic treatment and can seriously impact the patients’ QoL. The synergistic combination of dual HER2-targeted therapy with trastuzumab and pertuzumab plus endocrine therapy might offer a better treatment option for these patients. First clinical trials suggest an additional benefit when a CDK4/6 inhibitor is added to the combination of endocrine therapy and anti HER2 treatment. DETECT V is a randomized phase III study comparing the safety and efficacy of trastuzumab plus pertuzumab and the CDK 4/6 inhibitor ribociclib in combination with either endocrine therapy or chemotherapy.

Trial design:
Patients with HER2 positive and hormone-receptor positive MBC are 1:1 randomized to receive trastuzumab and pertuzumab combined with endocrine therapy and ribociclib or to chemotherapy with trastuzumab and pertuzumab followed by maintenance therapy with trastuzumab, pertuzumab, endocrine therapy and ribociclib. Chemotherapy and the endocrine agents can be chosen from a variety of available regimens according to the physicians discretion.

Specific aims:
The primary objective of this study is to compare safety and tolerability in both arms, as assessed by the occurrence of AEs during the treatment period. Secondary endpoints are progression free survival, overall survival, quality-adjusted survival using the quality-adjusted time without symptoms and toxicity (Q-TWIST) method. A translational program is included investigating detection and phenotyping of circulating tumor cells (CTC)-and the assessment of marker expression on CTCs in order to validate an endocrine responsiveness score.

Present accrual and target accrual:
The DETECT V trial started 2015 in the Dept. of Gynecology, University of Ulm and at the up to 120 sites in Germany. Until June 2018 97 patients with HER2-positive, hormone-receptor positive metastatic breast cancer have been enrolled. A sample size of 270 patients is planned.

Trastuzumab deruxtecan (DS-8201a) vs investigator's choice of treatment in subjects with HER2-positive, unresectable and/or metastatic breast cancer who previously received T-DM1: A randomized, phase 3 study

Fabrice André1, Javad Shahidi2, Caleb Lee2, Kongming Wang2 and Ian E Krop3. 1Institut Gustave Roussy, Villejuif, France; 2Daiichi Sankyo, Inc., Basking Ridge, NJ and 3Dana-Farber Cancer Institute, Boston, MA.

Background: There is no uniform standard of care for HER2-positive breast cancer (BC) after disease progression on ado-trastuzumab emtansine (T-DM1). DS-8201a is a novel HER2-targeted antibody-drug conjugate (ADC) with a humanized HER2 antibody attached to a topoisomerase I inhibitor payload by a cleavable peptide-based linker, and with a drug-to-antibody ratio of 7 to 8. It is designed with the goal of improving critical attributes of an ADC. In an ongoing phase 1 trial, DS-8201a showed promising antitumor activity in HER2-positive BC previously treated with T-DM1 (confirmed objective response rate [ORR] of 54.5%; April 2018 data cutoff; Iwata et al, ASCO 2018). Based on preliminary results from the phase 1 trial, DS-8201a received FDA breakthrough therapy and fast track designations for metastatic BC that progressed after prior treatment with T-DM1. The pivotal, phase 2 DESTINY-BREAST01 trial in this population with HER2-positive BC who received prior T-DM1 is ongoing (Baselga et al, ASCO 2018).

Study Description: This multicenter, open-label, phase 3 trial will assess the efficacy and safety of DS-8201a in subjects with HER2-positive (IHC 3+ or IHC 2+/ISH+; confirmed by centralized testing) unresectable and/or metastatic BC whose disease progressed on or after T-DM1 (NCT03523585, DESTINY-BREAST02). Approximately 600 subjects will be randomized (2:1) to DS-8201a or investigator's choice of treatment (trastuzumab plus capecitabine or lapatinib plus capecitabine). Randomization is stratified by hormone receptor status, prior pertuzumab treatment, and history of visceral disease. DS-8201a (5.4 mg/kg) will be administered IV once every 3 weeks. Progression free survival (PFS) based on blinded, independent central review using RECIST v1.1 criteria is primary efficacy endpoint; overall survival (OS) is the key secondary endpoint. Other secondary efficacy endpoints are ORR, duration of response, clinical benefit rate, and PFS based on investigator assessment. Safety assessments include serious and treatment-emergent adverse events, physical examinations, vital signs, and clinical laboratory parameters. Health-related quality of life will also be measured. The primary analysis for PFS will occur when approximately 372 PFS events have been observed; providing 90% power to detect a hazard ratio of 0.70 in PFS (a 43% improvement in median PFS from 3.3 months with investigator's choice to 4.7 months with DS-8201a) with a 1-sided alpha of 0.025. An interim OS analysis is planned at the time of the PFS analysis. Final OS analysis will occur when approximately 428 OS events have been observed. Long-term follow-up will continue after the primary analysis every 3 months until death, withdrawal of consent, loss to follow-up, or study closure. Efficacy analyses will include all randomized subjects, and safety analyses will include all randomized subjects who received ≥1 dose of study treatment. The study will enroll subjects from approximately 160 sites including in North and South America, Europe, and Asia. For further information on this trial, contact Fabrice André at FABRICE.ANDRE@gustaveroussy.fr or visit clinicaltrials.gov.
Trastuzumab deruxtecan (DS-8201a) vs ado-trastuzumab emtansine (T-DM1) for subjects with HER2-positive, unresectable and/or metastatic breast cancer who previously received trastuzumab and a taxane: A phase 3, randomized study

Sunil Verma¹, Javad Shahidi², Caleb Lee², Kongming Wang² and Javier Cortes³. ¹University of Calgary, Calgary, AB, Canada; ²Daiichi Sankyo, Inc., Basking Ridge, NJ and ³Ramón y Cajal Hospital, Madrid, Spain.

Background: Ado-trastuzumab emtansine (T-DM1), a HER2-targeted antibody drug conjugate (ADC), is approved for patients with HER2-positive metastatic breast cancer (BC) after disease progression on a trastuzumab-based regimen. Approval of T-DM1 was based on the EMILIA trial in which T-DM1 demonstrated an objective response rate (ORR) of 43.6%, a median progression-free survival (PFS) of 9.6 months, and an overall survival (OS) of 30.9 months (Verma S, et al. NEJM. 2012). DS-8201a is a novel HER2-targeted ADC with a humanized HER2 antibody attached to a topoisomerase I inhibitor payload by a cleavable peptide-based linker, and with a high drug-to-antibody ratio of 7 to 8. In an ongoing phase 1 trial, DS-8201a showed a manageable safety profile and promising antitumor activity in HER2-positive BC previously treated with T-DM1 (confirmed ORR of 54.5%; April 2018 data cutoff) (Iwata et al, ASCO 2018). The pivotal, phase 2 DESTINY-BREAST01 trial in this population with HER2-positive BC who received prior T-DM1 is ongoing (Baselga et al, ASCO 2018).

Study Description: This multicenter, open-label, phase 3 trial will assess the efficacy and safety of DS-8201a vs T-DM1 in subjects with HER2-positive (IHC 3+ or IHC 2+/ISH+; confirmed by centralized testing) unresectable and/or metastatic BC previously treated with trastuzumab and a taxane (NCT03529110, DESTINY-BREAST03). Subjects who previously received a HER2-targeted ADC are excluded. Approximately 500 eligible subjects will be randomized (1:1) to receive DS-8201a (5.4 mg/kg) or T-DM1 (3.6 mg/kg) IV once every 3 weeks. Randomization will be stratified by hormone receptor status, prior pertuzumab treatment, and history of visceral disease. For subjects randomized to T-DM1, the treatment will be in accordance with the approved label. The primary efficacy endpoint is PFS based on blinded, independent central review using RECIST v1.1 criteria. Secondary efficacy endpoints include OS, ORR, duration of response, clinical benefit rate, and PFS based on investigator assessment. Safety assessments include serious and treatment-emergent adverse events, physical examinations, vital signs, and clinical laboratory parameters. Health related quality of life will also be measured. The primary analysis for PFS will be performed when approximately 331 PFS events have been observed. This will provide 90% power to detect a hazard ratio of 0.70 for PFS with a 1-sided alpha of 0.025, assuming a median PFS with T-DM1 of 9.6 months and that PFS follows an exponential distribution. Long-term follow-up will continue after the primary analysis every 3 months until death, withdrawal of consent, loss to follow-up, or study closure. Efficacy analyses will include all randomized subjects, and safety analyses will include all randomized subjects who received ≥1 dose of study treatment. The study will enroll subjects from approximately 150 sites including in North America, Europe, and Asia.
A phase 1b study of poziotinib in combination with T-DM1 in women with advanced or metastatic HER2-positive breast cancer

Gajanan Bhat1, David Potter2, Jayaram Bharadwaj3, Nawazish Khan1, Lloyd Shabazz4, Jason Tache5 and Zane Yang1. 1Spectrum Pharmaceuticals, Irvine, CA; 2University of Minnesota, Minneapolis, MN; 3Pacific Cancer Medical Center, Anaheim, CA; 4Delta Hematology/Oncology Associates, Portsmouth, VA and 5BRCR Medical Center, Plantation, FL.

**Background:** Poziotinib represents a new class of irreversible quinazoline inhibitors of ErbB receptor tyrosine kinases that inhibit the proliferation of tumor cells in culture and in vivo by inhibiting HER-1 (EGFR), HER-2, HER-4. ErbB signaling plays important roles in the progression of HER2+ breast cancer. Poziotinib has promising clinical activity in breast cancer, and other solid tumors including lung, gastric, and colorectal cancers. Study SPI-POZ-101, is being conducted to evaluate the safety and efficacy of the combination of daily poziotinib and T-DM1, HER2 antibody-drug-conjugate every three weeks in patients with HER2+ advanced or metastatic breast cancer.

**Trial Objectives and Design:** The primary objectives of the study are to determine the maximum tolerated dose (MTD) or maximum administered dose (MAD) of daily poziotinib plus T-DM1 (every 3 weeks) in women with advanced or metastatic HER2 positive breast cancer; and to evaluate the Objective Response Rate (ORR) in these patients. The secondary objectives include disease control rate (DCR), progression-free-survival (PFS), safety and pharmacokinetics at the MTD/MAD dose level of poziotinib plus T-DM1.

In Part 1, the dose of poziotinib plus standard dose of T-DM1 (3.6 mg/kg IV) on Day 1 of each cycle will be determined using a “3+3” design with up to 3 escalating dose levels, 8, 10 and 12 mg with no DLT or to de-escalate to 6 mg with DLT observed in Cycle 1. Patients in current dose cohort, if not discontinued, will continue treatment until discontinuation of therapy.

In Part 2 of the study, approximately 10 patients will be treated at the MTD/MAD to confirm dose for safety of the combination and to evaluate preliminary efficacy.

**Eligibility Criteria:** The study will enroll female patients between 18 and 90 years with confirmed HER2 overexpression or gene-amplified tumor via immunohistochemistry [IHC] with IHC 3+ or IHC 2+ with confirmatory fluorescence in situ hybridization [FISH]+ or [ISH]+ and must have had at least 2 lines of anti-HER2 directed therapies either in the metastatic or early-stage disease setting. Patients must have adequate hematologic, hepatic, cardiac and renal functions and have at least one measurable lesion per RECIST 1.1 criteria. Exclusion criteria includes unstable CNS metastases or seizure disorder; anticancer chemotherapy, TKIs, biologics, immunotherapy, radiotherapy, or investigational treatment within 15 days; ≥ Grade 2 adverse events; known hypersensitivity to receptor tyrosine kinase inhibitors or any of the components of poziotinib tablets or T-DM1 IV solution.

**Statistical Methods:** Part 1 of the study will enroll 3 to 6 patients at each dose using 3+3 design. Part 2 will enroll 10 patients at the MTD/MAD. The efficacy analysis will be conducted using the Evaluable Population based on RECIST 1.1. The Clopper-Pearson 95% confidence interval will be estimated using exact method based on binomial distribution.

**Target Accrual:** Part 1: 6-18 patients Part 2: 10 patients

**ClinicalTrials.gov Identifier:** NCT03429101

**Contact Information:** Spectrum Pharmaceuticals. SPI-POZ-101@sppirx.com

Poziotinib is currently under clinical investigation and has not been approved for use in breast cancer.
A phase III trial to compare eribulin mesylate + trastuzumab (H) + pertuzumab (P) with paclitaxel or docetaxel + HP for HER2-positive advanced or metastatic breast cancer (JBCRG-M06/ EMERALD)

Norikazu Masuda¹, Toshinari Yamashita², Shigehira Saji³, Kazuhiro Araki⁴, Yoshinori Ito⁵, Toshimi Takano⁶, Masato Takahashi⁷, Junji Tsurutani⁸, Kei Koizumi⁹, Masahiro Kitada¹⁰, Yasuyuki Kojima¹¹, Yasuaki Sagara¹², Hiroshi Tada¹³, Tsutomu Iwasa⁶, Takayuki Kadoya¹⁴, Tsuguo Iwatani¹¹, Hiroki Hasegawa¹⁵, Satoshi Morita¹⁶ and Shinji Ohno⁶. ¹NHO Osaka National Hospital, Osaka, Japan; ²Kanagawa Cancer Center, Yokohama, Japan; ³Fukushima Medical University Hospital, Fukushima, Japan; ⁴Hyogo College of Medicine, Nishinomiya, Japan; ⁵The Cancer Institute Hospital of JFCR, Tokyo, Japan; ⁶Toranomon Hospital, Tokyo, Japan; ⁷NHO Hokkaido Cancer Center, Sapporo, Japan; ⁸Kindai University Hospital, Osaka-Sayama, Japan; ⁹Seirei Hamamatsu General Hospital, Hamamatsu, Japan; ¹⁰Asahikawa Medical University Hospital, Asahikawa, Japan; ¹¹St. Marianna University School of Medicine Hospital, Kawasaki, Japan; ¹²Sagara Hospital, Kagoshima, Japan; ¹³Tohoku University Hospital, Sendai, Japan; ¹⁴Hiroshima University Hospital, Hiroshima, Japan; ¹⁵Eisai Co., Ltd., Tokyo, Japan and ¹⁶Graduate School of Medicine Kyoto University, Kyoto, Japan.

**Background:** Docetaxel + Trastuzumab (H) + Pertuzumab (P) provided progression-free survival (PFS) and overall survival (OS) benefits in HER2-positive advanced or metastatic breast cancer (AMBC) in the CLEOPATRA study as a first-line therapy. However, long-term administration of docetaxel at a dose of 75 mg/m² every 3 weeks in AMBC patients (pts) is difficult due to the toxicities. Eribulin mesylate (E) is a well-tolerated microtubule inhibitor, and we have reported the efficacy and safety of EHP regimen as first- and second-line therapy for AMBC in a multicenter, phase II study (JBCRG-M03/UMIN000012232). In this M06 study, we address the clinical question as to which is the better chemotherapy partner for HP as first line regimen, in terms of efficacy, toxicity and QOL.

**Methods:** JBCRG-M06 is a multicenter open-label randomized phase III study for HER2-positive AMBC pts who have received no prior chemotherapy except for the HER2- Antibody-Drug Conjugate (ADC). Pts will be randomized 1:1 to E (1.4mg/m² on day 1 and 8) + H (8 mg/kg loading dose followed by 6 mg/kg) +P (840 mg loading dose followed by 420 mg) q3wks or standard taxanes (docetaxel 75mg/m² on day 1 or paclitaxel 80mg/m2 on day 1, 8 and 15) + HP q3wks. Stratification factors for randomization are: presence of visceral metastases, number of prior taxanes on perioperative adjuvant treatment, and treatment with prior anti-HER2-ADC. Primary endpoint is PFS and secondary endpoints include overall response rate, duration of response, OS, patient-reported outcomes (PRO) relating to QOL and peripheral neuropathy, new-metastases free survival, and safety. Translational research to search for biomarker for individual precision therapy will be performed. Main eligibility criteria are as follows: pts with HER2-positive AMBC, female aged 20-70 years old, ECOG PS of 0-1, LVEF ≥ 50% at baseline and adequate organ function. Pts who had progressive MBC within 6 months after the end of primary adjuvant systemic chemotherapy are excluded. The sample size was calculated by type1 error (2-sided) of 0.05 and 80% power to estimate the noninferiority margin 1.33 with an expected median PFS of 14.2 months. The target number of pts is 480 recruited over the duration of 3-years. The first patient in was achieved on August 2017. (ClinicalTrials.gov Identifier:NCT03264547).
Antibody-coupled T cell receptor (ACTR) engineered autologous T cells in combination with trastuzumab for the treatment of HER2-positive malignancies

Katie M O’Callaghan¹, John Shin¹, Alexander S Cheung¹, Tooba Cheema¹, Casey Judge¹, Ann Ranger¹, Heather A Huet¹, Seth A Ettenberg¹, Jessica Sachs¹, Michael Vasconcelles¹ and Greg Motz¹. ¹Unum Therapeutics Inc., Cambridge, MA.

Antibody-Coupled T cell Receptor (ACTR) is an autologous engineered T cell therapy developed to combine with tumor-targeting antibodies to exert potent anti-tumor immune responses and tumor cell killing. The ACTR construct is composed of the extracellular domain of CD16 fused to CD3ζ signaling and T cell co-stimulatory domains. ACTR-expressing T cells are universal in that they can be paired with a therapeutic antibody to target specific antigens on tumors. Unum has two ACTR constructs, ACTR087 and ACTR707, currently in clinical testing. ACTR087 and ACTR707 are being tested in combination with rituximab in subjects with CD20+ B cell lymphoma in two separate trials (NCT02776813 and NCT03189836, respectively). Preliminary data with ACTR087 + rituximab has demonstrated clinical proof-of-concept and a dose-response relationship in subjects with relapsed/refractory B cell lymphoma. ACTR087 is also being tested in combination with a novel BCMA-targeting antibody in subjects with multiple myeloma (NCT03266692).

While T cell therapies, such as chimeric antigen receptor (CAR) T cells, have demonstrated clinical activity in hematological cancers, the therapeutic potential of this approach has yet to be established in solid tumors. Challenges associated with targeting solid tumors with CAR-T cells include tumor antigen heterogeneity and antigen expression on normal tissues. HER2 is a well-established therapeutic target that is over-expressed in a number of cancer indications. HER2 is also expressed at low levels on normal epithelial cells, creating a risk for on-target/off-tumor toxicities of HER2-targeted CAR-T cells. Here we present nonclinical studies demonstrating that ACTR T cells in combination with trastuzumab have antigen density-dependent activity on HER2-expressing tumor cell lines, while trastuzumab-based CAR-T cells do not. We observed that ACTR + trastuzumab had robust activity against HER2-amplified tumor cells and more modest activity against non-amplified tumor cells, whereas HER2-targeting CAR-T cells had comparable activity against HER2-amplified and non-amplified tumor cells. On normal human primary cells, ACTR + trastuzumab had minimal activity in comparison to HER2 CAR-T cells, suggesting that ACTR + trastuzumab may exhibit a superior clinical therapeutic index. Furthermore, the activity of ACTR T cells against HER2-amplified tumor cells was titratable with antibody concentration, allowing for control of ACTR activity by modulation of trastuzumab concentration. Together, these data demonstrate the specificity of the ACTR T cell therapeutic approach to target HER2-amplified tumors and support clinical testing in combination with trastuzumab.

A phase 1, multicenter, single-arm, open-label dose escalation study, ATTCK-34-01, is proposed to evaluate ACTR T cells in combination with trastuzumab in subjects with advanced HER2-positive malignancies. The primary study objectives are to assess the safety and tolerability of the combination, and to define the recommended phase 2 dose combination for further study. Additional objectives include assessment of anti-tumor activity, ACTR T cell persistence and trastuzumab pharmacokinetics. Enrollment is expected to commence in early 2019.
Image-guided de-escalation of neoadjuvant chemotherapy in HER2-positive breast cancer: The TRAIN-3 study

Anna van der Voort1, Vincent O Dezentjé2, Wim A van der Steeg5, Gonneke AO Winter-Warnars1, Robert-Jan Schipper1, Astrid N Scholten1, Jelle Wesseling1, Erik D van Werkhoven1, Frederique H van Duijnhoven1, Marie-Jeanne TFD Vrancken Peeters1 and Gabe S Sonke1. 1The Netherlands Cancer Institute, Amsterdam, Netherlands and 2Isala, Zwolle, Netherlands.

Background
The addition of pertuzumab to trastuzumab containing chemotherapy has boosted pathologic complete response (pCR) rates after neoadjuvant chemotherapy for HER2-positive breast cancer. PCR rates over 80% have been described and achieving a pCR is associated with a favorable long-term outcome. In addition, achieving a radiologic complete response (rCR) is predictive of the pathologic response in HER2-positive tumors. Therefore it is hypothesized that image-guided evaluation based on the early occurrence of rCR can be used to tailor the number of chemotherapy cycles.

Trial design
This is a single arm, multicenter study evaluating the efficacy of image-guided de-escalation of neoadjuvant treatment with paclitaxel, Herceptin®, carboplatin, and pertuzumab (PTC-ptz). Radiologic evaluation with contrast-enhanced breast MRI and ultrasound of the axilla (in cN+ patients) is performed at baseline and after 3, 6, and 9 cycles of treatment. In case of rCR of the breast (and axilla) after 3 or 6 cycles, early surgery will be performed. If residual tumor is present after 3 and 6 cycles, patients will continue the PTC-ptz regimen to complete a total of 9 cycles. All patients will receive adjuvant Herceptin® and pertuzumab to complete 1 year of anti-HER2 blockade and endocrine treatment according to local guidelines if HR-positive. The study will be performed in the Netherlands in approximately 35 centers.

Eligibility criteria
Eligible patients have histologically proven stage II/III HER2-positive primary breast cancer with known hormone-receptor status. Patients must have a measurable breast tumor on baseline MRI and can be either node negative or node positive.

Specific aims
The aim is to evaluate the efficacy of image-guided de-escalation of neoadjuvant chemotherapy in HER2-positive breast cancer on event-free survival (EFS) at 3 years as primary endpoint. Secondary endpoints are overall survival, rCR, concordance between rCR and pCR (ypT0/is, ypN0), differences in EFS and OS following pCR between patients who received 3, 6, or 9 cycles, and toxicity.

Statistical methods
This is a single-arm, two stage study with one interim-analysis and a final analysis. Statistics will be performed for each hormone receptor subgroup separately. Stopping rules are based on 3-year EFS-rates described in literature (88% for HR-negative tumors and 90% for HR-positive tumors) and calculated using the exact conditional Poisson distribution. The study is successful with ≤34 EFS-events in the HR-negative subgroup and ≤38 events in the HR-positive subgroup after 700 patient-years of follow-up. The three-year EFS-estimate will be calculated using Kaplan-Meier statistics.

Present accrual and target accrual
Target accrual is 231 patients for the HR-negative group and 231 patients for the HR-positive group. Present accrual will follow.

Funding
Investigator initiated trial sponsored by the Dutch Breast Cancer Research Group (BOOG), funded by Roche.

A phase Ib study of neratinib, pertuzumab, and trastuzumab with paclitaxel in patients with metastatic and locally advanced breast cancer

Aydah Al-Awadhi1,3, Miho Kono2,3, Angela Marx2,3, Tanya Moseley2, Jie Willey2,3, Huiming Sun2,3, Min Fu2,3, Gary J Whitman2, Vicente Valero2,3, Naoto T Ueno2,3 and Bora Lim2,3. 1Cancer Medicine Fellowship Program, The University of Texas MD Anderson Cancer Center, Houston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX and 3Morgan Welch Inflammatory Breast Cancer Research Program and Clinic, The University of Texas MD Anderson Cancer Center, Houston, TX.

**Background:** Neratinib, a potent irreversible pan-ErbB tyrosine kinase inhibitor that blocks signal transduction through HER1, HER2, and HER4, has demonstrated activity against metastatic HER2-positive breast cancer (HER2+ BC) in patients pretreated with trastuzumab. The FDA recently approved neratinib as an adjuvant treatment for HER2+ BC patients who have received trastuzumab for at least 1 year. Preclinical data demonstrate that trastuzumab-resistant BC cells remain sensitive to neratinib. Also, neratinib enhances responses to trastuzumab possibly by increasing trastuzumab's internalization, immune-mediated action, and other mechanisms. Taken together, these findings provide the rationale for adding neratinib to the standard of care combination of trastuzumab and pertuzumab with paclitaxel to enhance anti-HER2 efficacy in advanced HER2+ BC. Here, we report on the phase Ib portion of an ongoing phase Ib/II trial of this drug combination.

**Trial Design:** Patients with metastatic or locally advanced HER2+ BC will be enrolled in the phase Ib portion of the trial. Neratinib is given orally in 3-week cycles. The initial neratinib dose of 80 mg daily is increased to 120, 160, and 200 mg daily after safety assessments of each dose level. Other agents are administered as per the standard of care. Patients continue therapy with per-protocol dose escalation and de-escalation according to toxicity until the maximum tolerated dose (MTD) of neratinib is reached. The target maximum dose-limiting toxicity rate is 20%. All patients receive 4 cycles of the combination therapy. If patients do not have disease progression or excessive toxicity, they may receive 2-4 additional cycles at the treating physician's discretion. During therapy, patients undergo blood tests every week and have clinical visits and restaging scans every 3 weeks. Because gastrointestinal toxicity, mainly diarrhea, is anticipated, patients receive prophylactic antidiarrheal medication (e.g., loperamide, budesonide) beginning with the first dose of neratinib.

**Eligibility Criteria:** Eligible patients must have histologically confirmed metastatic or locally advanced HER2+ BC (BC may be inflammatory or non-inflammatory and have any hormone receptor status); an ECOG performance status score of 0 or 1; and adequate hematologic and organ function, including adequate cardiac function (as indicated by a left ventricle ejection fraction of ≥50%).

**Specific Aims:**
1- To determine the MTD of neratinib in combination with paclitaxel, pertuzumab, and trastuzumab.
2- Pharmacodynamic markers will be measured on biologic specimens. Neratinib-induced changes in pEGFR and/or HER2 expression will be analyzed and compared between dose levels.

**Statistical Methods:** The Bayesian modified toxicity probability interval is used to determine dose adjustment.

**Accrual:** The target enrollment for the phase Ib cohort is 20 patients. The trial has enrolled 3 patients since its activation in January 2018. This trial is supported by Puma Biotechnology, Aggressive Breast Cancer Research Program Grant.
Personalized breast cancer screening in a population based study: Women Informed to Screen Depending On Measures of risk (WISDOM)

Irene Acerbi¹, Yiwey Shieh¹, Lisa Madlensky², Jeffrey Tice¹, Elad Ziv¹, Martin Eklund¹, Amie Blanco¹, Diana DeRosa², Barry Tong¹, Deborah Goodman¹, Lamees Nassereddine³, Nancy Anderson⁶, Heather Harvey⁶, Tracy Layton², Hannah L Park⁴, Antonia Petrusen⁵, Skye Stewart³, Janet Wernisch⁶, Larissa Risty⁶, Barbara Koenig¹, Setareh Sarrafan¹, Roxanna Firouzian¹, Celia Kaplan¹, Robert Hiatt¹, Barbara A Parker², Neil Wenger⁵, Vivian Lee¹, Diane Heditians¹, Susie Brain¹, Allison Stover Fiscalini¹, Alexander D Borowsky⁴, Hoda Anton-Culver⁴, Arash Naeim⁵, Andrea Kaster⁶, Melinda Talley⁵, Laura J van 't Veer¹, Andrea LaCroix², Wisdom Study and Athena Breast Health Network Investigators and Advocate Partners¹ and Laura J Esserman¹. ¹University of California, San Francisco, San Francisco, CA; ²University of California, San Diego, San Diego, CA; ³University of California, Davis, Sacramento, CA; ⁴University of California, Irvine, Irvine, CA; ⁵University of California, Los Angeles, Los Angeles, CA; ⁶Sanford Health, Sioux Falls, SD and ⁷Karolinska Institutet, Stockholm, Sweden.

Background: WISDOM is a 100,000 healthy women preference-tolerant, pragmatic study comparing annual to personalized risk-based breast screening. The novelty of WISDOM personalized screening is the integration of previously validated genetic and clinical risk factors (age, family history, breast biopsy results, ethnicity, mammographic density) into a single risk assessment model that directs the starting age, timing, and frequency of screening. The goal of WISDOM is to determine if personalized screening, compared to annual screening, is as safe, less morbid, enables prevention, and is preferred by women. The study is registered on ClinicalTrials.gov, NCT02620852.

Methods: Women aged 40-74 years with no history of breast cancer or DCIS, and no previous double mastectomy can join the study online at wisdomstudy.org. Participants can elect randomization or self-select a study arm, and provide electronic consent and Release for Medical Information using DocuSign. For all participants, 5-year risk of developing breast cancer is calculated according to the Breast Cancer Screening Consortium (BCSC) model. Participants in the personalized arm undergo panel-based mutation testing, and their 5-year risk is calculated using the BCSC score combined with a Polygenic Risk Score (BCSC-PRS) that includes 75 single nucleotide polymorphisms (SNPs, increase to 229) known to increase breast cancer risk. SNPs and mutations (BRCA1, BRCA2, TP53, PTEN, STK11, CDH1, ATM, PALB2, and CHEK2) are assessed by saliva-based testing through Color Genomics. 5-year risk level thresholds are used to stratify for low-, moderate- and high risk. Risk stratification determines age to start, stop, and frequency of screening.

Enrollment: As of July 2018, the WISDOM study is open to all eligible women in California, North Dakota, South Dakota, Minnesota and Iowa. To date, 23,329 eligible women have registered and 14,393 women have consented to participate in the trial. We analyzed 3,255 participants who have completed risk assessment in the personalized arm. The median age was 56 years. 82% were Caucasian, 1% African-American, and 6% Asian. 9% self-reported as Hispanic. We are partnering with health insurers and self-insured companies using coverage with evidence progression. To strengthen generalizability, we are expanding to other states. WISDOM enrollment will continue past 2019.

Feasibility: To evaluate the addition of PRS, we used paired statistical tests (McNemar) to compare the distributions of BCSC, and BCSC-PRS risk estimates around low-risk (<1.3%), and very-high-risk (>6%) thresholds, the latter corresponding to 5-year risk of a BRCA mutation carrier. The median 5-year risk was 1.5% (IQR 1.0-2.1%) using the BCSC model, and 1.4% (IQR 0.8-2.5%) using the BCSC-PRS model. The BCSC-PRS model classified more women into the low (<1%) and very high (≥6%) risk categories compared to the BCSC model (p < 0.001).

Conclusions: Our findings demonstrate that incorporating genetic variants into a validated clinical model is feasible and impacts risk classification compared to a model without genetic risk factors. Results at 5 years will reveal if this classification improves healthcare value by reducing screen volumes and costs without jeopardizing outcomes.
Pilot study of denosumab in \textit{BRCA1/2} mutation carriers scheduling for risk-reducing salpingo-oophorectomy

Meghna S Trivedi\textsuperscript{1}, Goli Samimi\textsuperscript{2}, Jason D Wright\textsuperscript{1}, Kevin Holcomb\textsuperscript{3}, Judy E Garber\textsuperscript{4}, Neil S Horowitz\textsuperscript{5}, Nadir Arber\textsuperscript{5}, Eitan Friedman\textsuperscript{6}, Robert M Wenham\textsuperscript{7}, Margaret House\textsuperscript{2}, Howard Parnes\textsuperscript{2}, J Jack Lee\textsuperscript{8}, Saba Abutaseh\textsuperscript{8}, Lana A Vornik\textsuperscript{8}, Brandy M Heckman-Stoddard\textsuperscript{2}, Powel H Brown\textsuperscript{8} and Katherine D Crew\textsuperscript{1}. \textsuperscript{1}Columbia University Medical Center, New York, NY; \textsuperscript{2}National Cancer Institute, NIH, Bethesda, MD; \textsuperscript{3}Weill Cornell Medical Center, New York, NY; \textsuperscript{4}Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA; \textsuperscript{5}Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; \textsuperscript{6}Chaim Sheba Medical Center, Tel-Hashomer, Israel; \textsuperscript{7}Moffitt Cancer Center, Tampa, FL and \textsuperscript{8}University of Texas MD Anderson Cancer Center, Houston, TX.

\textbf{Background}: Denosumab is a monoclonal antibody that inhibits RANKL and is approved for the prevention of fractures in patients with osteoporosis or bone metastases. The RANKL signaling pathway is also involved in \textit{BRCA1}-associated mammary tumorigenesis via a progesterone-induced paracrine effect of RANKL on luminal progenitor cells. Pre-clinical studies have demonstrated that RANKL inhibition resulted in reduced proliferation of mammary tumors. Early findings from an ongoing presurgical study demonstrated that denosumab treatment resulted in decreased Ki67 proliferation index in benign breast tissue. Based on these data, denosumab is being pursued as a potential preventive agent for breast cancer in \textit{BRCA1} mutation carriers.

While promising, the effect of RANKL inhibition on gynecologic tissues such as the ovaries and fallopian tubes, in which progesterone has a protective effect, is unknown.

\textbf{Trial design}: We will conduct a multicenter, open-label randomized pilot study of presurgical administration of denosumab versus no treatment in premenopausal women with \textit{BRCA1/2} mutations undergoing risk-reducing salpingo-oophorectomy (RRSO). A total of 60 women will be randomized 1:1 to Arm 1) 3-4 doses of 120 mg denosumab subcutaneously every 4 weeks or Arm 2) No treatment. Participants will be stratified by 1) \textit{BRCA1} versus \textit{BRCA2} mutation status and 2) Use of hormonal contraceptives within the past 3 months (yes/no). Assuming a 10\% un evaluable rate, we expect to have 54 evaluable participants (27 per arm).

\textbf{Eligibility criteria}: 1) Premenopausal women (defined as < 3 months since last menstrual period or serum follicle-stimulating hormone (FSH) < 20 mIU/mL), age ≥ 18 years; 2) Documented germline pathogenic mutation or likely pathogenic variant in the \textit{BRCA1} or \textit{BRCA2} gene; 3) Plan for RRSO with or without hysterectomy; 4) ECOG performance status ≤ 1 (Karnofsky ≥ 70\%); 5) Normal organ and marrow function; 6) Negative pregnancy test and use of adequate contraception; 7) Willingness to take supplemental oral calcium and vitamin D3; 8) Dental examination within 6 months of enrollment and no evidence of active dental issues; 9) Ability to understand and willingness to provide informed consent.

\textbf{Specific aims}: Our primary objective is to compare the effect of denosumab to no treatment on Ki67 expression in the fimbrial end of the fallopian tube. Secondary objectives are to assess Ki67 in ovary and endometrium; cleaved caspase-3, RANK/RANKL, ER/PR, CD44, and STAT3/pSTAT3 expression in fallopian tube, ovary, and endometrium; gene expression profiling in the fallopian tube and ovary; serum markers (progesterone, estradiol, C-terminal telopeptide) and denosumab levels; and toxicity.

\textbf{Statistical methods}: The primary endpoint is post-treatment Ki67 expression in the fimbrial end of the fallopian tube in the denosumab arm compared to the no treatment arm. Assuming a standard deviation of 5.0\%, we will have 82\% power to detect a 4.0\% absolute difference (or effect size of 0.8) in Ki67 proliferation index between the denosumab and no treatment groups by applying a 2-sample t-test at a 0.05 significance level.

\textbf{Target accrual}: 60 participants, to be activated in Summer 2018.
A phase I dose escalation study of topical bexarotene in women at high risk for breast cancer

Parijatham S Thomas¹, Anisha B Patel¹, Alejandro Contreras¹, Diane D Liu¹, J Jack Lee¹, Seema Khan², Lana A Vornik¹, Eileen P Dimond³, Marjorie Perloff³, Brandy M Heckman-Stoddard³ and Powel H Brown¹. ¹University of Texas at MD Anderson Cancer Center, Houston, TX; ²Northwestern University, Chicago, IL and ³National Cancer Institute, Bethesda, MD.

Background: Breast cancer prevention with anti-estrogens, including tamoxifen, raloxifene, and exemestane, has been shown to reduce the incidence of hormone receptor-positive breast cancer. However, agents that can reduce the incidence of hormone receptor negative breast cancer are currently lacking. Rexinoids such as bexarotene are vitamin A analogues that have been shown to be involved in cell differentiation, growth, and apoptosis. In preclinical mouse models that develop ER-negative breast cancers, bexarotene showed a significant reduction in mammary tumor development. Oral bexarotene has been evaluated in BRCA mutation carriers and significant decreases in cyclin D1 were noted in breast cells suggesting biological activity of bexarotene on breast tissue. Systemic side effects of hyperlipidemia and hypothyroidism were also found. Data from chemoprevention studies with topical 4-hydroxytamoxifen support the concept of topical agents penetrating into the breast tissue and exhibiting biological activity in the tissue. We hypothesize that topical bexarotene can be applied to the breast as a chemoprevention agent with penetration to the breast tissue without subsequent systemic side effects and toxicity as seen with oral bexarotene.

Trial Design: Women at high risk for breast cancer will be recruited and assigned to one of three different dose levels: 10mg (1ml) every other day, 10mg (1ml) daily, 20mg (2ml) daily to one unaffected breast for 4 weeks. The primary endpoint of the study is to determine the recommended phase II dose of topical bexarotene 1% gel for evaluation in healthy at-risk women. Dose Limiting Toxicity (DLT) is defined as a grade 2 skin adverse event that persists for at least 6 days or any grade 3 or greater adverse event related to the study drug. A grade 2 skin adverse event that recurs and persists for at least 3 days is also a DLT. The Maximum Tolerated Dose (MTD) will be defined as the highest dose level at which no more than 2 participants experience a DLT among 10 participants treated. A conservative modification of the standard “3+3” design will be applied. The first three participants will be assigned to the lowest dose level. New cohorts of 3-4 participants will not be treated until toxicity has been fully evaluated for all current participants through 4 weeks. Once the MTD has been determined, an expansion cohort of an additional 10 patients will be recruited at the MTD to further evaluate safety and toxicity at this dose level as well bexarotene concentration in the breast tissue. Secondary endpoints include serum bexarotene level, tissue bexarotene levels, and changes in thyroid function tests, lipid profile, and calcium. The planned accrual for this study if maximally accrued to all dose levels and the dose expansion cohort will be 40 participants.
Treatment burden and capacity to manage care among patients with breast cancer

Alex Cheng1 and Mia Levy1. 1Vanderbilt University Medical Center, Nashville, TN.

Patients with breast cancer spend significant time1, effort, and financial resources2 to combat the disease for years after their diagnosis. The large volume of healthcare tasks can cause patients to become overburdened, leading to reduced adherence with care plans and worse outcomes3. On the other hand, certain patient characteristics such as physical resilience, financial well-being, and supportive family environments increase patients' capacity to manage care4. Assessing treatment burden and capacity when prescribing care has been applied to populations such as diabetes patients5. We are investigating this paradigm in treatment of patients with breast cancer. The goal of this preliminary study is to identify significant factors that contribute to treatment burden, capacity to manage care, and outcomes of overburden for patients with breast cancer.

Examples of treatment burden, capacity to manage care, and outcomes of overburden in patients with breast cancer

</table>

Through literature review, interviews with survivors, and expert panels of navigators and providers, we will develop a survey instrument given to patients at the time of diagnosis. The survey will assess patient capacity and help providers give treatment options based on attributes of the patient. Additionally, we will attempt to correlate survey results with treatment burden measures derived from electronic health record data at a population level1. With treatment personalized for patient capacity, patients should be better able to adhere to care plans leading to improved quality of life during treatment and beyond.

BEGONIA: Phase Ib/II open-label, platform study of safety and efficacy of durvalumab, paclitaxel and other novel oncology therapy agents as first-line (1L) therapy in patients with metastatic triple negative breast cancer (mTNBC)

Peter Schmid¹, Ana T Nunes², Rajuli Lall², Celina D’Cruz², Lynda Grinsted³ and Mark C Lanasa². ¹St Bartholomew’s Hospital & Barts Cancer Institute, London, United Kingdom; ²AstraZeneca, Gaithersburg, MD and ³AstraZeneca, Cambridge, United Kingdom.

Background: Immuno-oncology therapies have shown durable clinical responses in a subset of patients with mTNBC. Combination therapy with checkpoint inhibition and chemotherapy is under investigation; preliminary research showed improved objective response rate (ORR) with combination therapy versus chemotherapy alone.¹ Durvalumab is a selective, high-affinity, engineered, human monoclonal antibody that blocks programmed cell death-ligand 1 (PD-L1) binding to programmed cell death 1 (PD-1) and CD80 allowing T cells to recognize and kill tumor cells. This study is designed to assess the efficacy and safety of durvalumab + paclitaxel as 1L treatment in patients with mTNBC. Additionally, this study will also evaluate potential novel triplet treatment regimens of durvalumab + paclitaxel in combination with immune-modulating agents, selumetinib (ARRY-142886; AZD6244, an inhibitor of mitogen activated protein kinase/extracellular signal regulated kinase [MAPK/ERK]), danvatirsen (AZD9150, an antisense oligonucleotide designed to down-regulate expression of signal transducer and activator of transcription 3 protein), oleclumab (MEDI9447, an anti-CD73 monoclonal antibody), and capivasertib (AZD5363, a highly selective, oral, small molecule AKT inhibitor) that may provide further benefit to patients with mTNBC.

Methods: BEGONIA is a phase Ib/II, open-label, multicenter, platform study (EudraCT No: 2018-000764-29) consisting of 2 parts: Part 1 is a phase Ib study planned to be conducted in approximately 100 patients (20 per arm) to assess the safety and tolerability of durvalumab (1500 mg intravenous [IV], q4w) + paclitaxel (90 mg/m² IV, 4 week cycle, 3 weeks once weekly [days 1, 8, 15], 1 week off) (arm 1); and durvalumab + paclitaxel in combination with selumetinib (arm 2), danvatirsen (arm 3), oleclumab (arm 4) and capivasertib (arm 5) until disease progression. Dosing of the immune-modulating agents will be based on the previously defined recommended phase 2 doses of the component doublets (where available) in combination with durvalumab + paclitaxel using a rolling 6-patient design to evaluate for toxicity. Part 2 is a phase II study planned to be conducted in approximately 150 to 225 patients to evaluate efficacy of up to 2 best triplet combination arms based on their safety and efficacy outcomes in Part 1. The primary objective of Part 1 is safety and of Part 2 is efficacy (primary endpoint: progression free survival [PFS]); additionally, efficacy will be assessed in both parts, including overall survival, ORR, PFS, and duration of response (RECIST 1.1). Immunotherapy naïve adult patients (≥18 years) with locally assessed and confirmed TNBC, ECOG PS 0 or 1, stage IV breast adenocarcinoma and no prior systemic treatment for metastatic disease will be enrolled.

RIBANNA — Real-world evidence of ribociclib plus aromatase inhibitor, or endocrine monotherapy, or chemotherapy as first-line therapy for postmenopausal women with HR+, HER2– advanced breast cancer (aBC)

Achim Wöckel1, Peter A Fasching2, Gernot Guderian3, Julia Heim3, Christian Jackisch4, Hans-Joachim Lück5, Diana Lüftner6, Frederik Marmé7, Toralf Reimer8 and Thomas Decker9. 1University Hospital Würzburg, Würzburg, Germany; 2University Hospital Erlangen, Comprehensive Cancer Center Erlangen-EMN, Erlangen, Germany; 3Novartis Pharma GmbH, Nuremberg, Germany; 4Sana Klinikum, Offenbach, Germany; 5Gynäkologisch-Onkologische Schwerpunktpraxis, Hannover, Germany; 6Charité University Hospital, Berlin, Germany; 7National Center for Tumor Diseases and University Hospital, Heidelberg, Germany; 8Klinikum Südstadt, University of Rostock, Rostock, Germany and 9Onkologie Ravensburg, Ravensburg, Germany.

Background: In the pivotal phase 3 MONALEESA-2 trial, ribociclib, a highly selective oral CDK4/6 inhibitor in combination with letrozole significantly prolonged progression-free survival (PFS) compared to letrozole alone. In the year 2017, based on the results of MONALEESA-2, ribociclib in combination with an aromatase inhibitor (AI) was approved for the treatment of HR+, HER2– aBC in postmenopausal women with no prior therapy for their advanced disease (first-line treatment). Beyond phase 3 trials, further data for ribociclib are now becoming available from the phase 3b trials, RIBECCA and COMPLEEMENT-1, involving approximately 500 and 3000 patients with aBC, respectively. However, real-world evidence for the effectiveness, safety, and tolerability of ribociclib + AI in the routine clinical practice is needed to further support the use of this combination in the first-line therapy.

Methods: RIBANNA is a non-interventional study, which started in October 2017 and plans to enroll 3020 patients across ~400 sites in Germany. Postmenopausal women diagnosed with aBC will be enrolled into 3 cohorts (cohort 1: ribociclib + AI; cohort 2: endocrine monotherapy; and cohort 3: chemotherapy). Across all cohorts, patients will be treated in accordance with the respective German-prescribing guidelines. Data related to efficacy (with PFS as the primary efficacy criterion), safety, tolerability, duration of therapy, and impact on quality of life (QoL) will be collected. QoL will be assessed using the validated patient questionnaires. This study was especially designed to analyze the patient data from sequential lines of therapy in all three cohorts over a period of up to 7 years. For this purpose, RIBANNA will collect the data on each line of treatment and the reason for changing treatment in all 3 cohorts. The same accounts for QoL, which will also be assessed periodically, regardless of disease progression and initiation of subsequent therapies.

RIBANNA is the first study to provide the real-world evidence regarding treatment of HR+, HER2– aBC with the CDK4/6 inhibitor, ribociclib. This study includes 3 treatment cohorts (ribociclib + AI, endocrine monotherapy, and chemotherapy) with subsequent treatment algorithms and assessment of QoL over the entire study period.
PATHWAY: Asian, multicenter, phase 3 trial of tamoxifen with or without palbociclib ± goserelin in women with hormone receptor-positive, HER2-negative advanced or metastatic breast cancer

Emi Noguchi1, Tomomi Hata1, Kenichi Nakamura1, Aya Kuchiba1, Mitsuhiro Hayashi2, Akinobu Hamada2, Kan Yonemori1, Joohyuk Sohn3, Yen-Shen Lu4, Yoon-Sim Yap5, Yasuhiro Fujiwara1 and Kenji Tamura1. 1National Cancer Center Hospital, Tokyo, Japan; 2National Cancer Center Research Institute, Tokyo, Japan; 3Yonsei University Severance Hospital, Seoul, Korea; 4National Taiwan University Hospital, Taipei, Taiwan and 5National Cancer Center Singapore, Singapore, Singapore.

BACKGROUND:
The incidence rates of breast cancer (BC) in Asian counties have been rising rapidly. The age-specific female BC incidence rates peak before menopause (around 40-50 years of age) in Asia, however treatment options for pre/perimenopausal patients are limited. Palbociclib (P) is an oral novel cyclin-dependent kinase 4/6 (CDK4/6) inhibitor. The addition of P to endocrine therapy (ET) such as aromatase inhibitor or fulvestrant has been demonstrated improved progression-free survival (PFS) in phase 3 studies PALOMA-2 and PALOMA-3. This study is designed to evaluate efficacy and safety of P plus tamoxifen (TAM) in patients with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative advanced or metastatic BC regardless of menopausal status. This study is conducted as a Clinical Research Collaboration by National Cancer Center Hospital with research funding from Pfizer.

TRIAL DESIGN:
PATHWAY/NCCH1607 is a double-blind, placebo-controlled, randomized, phase 3 study. Patients will be randomized 1:1 to receive either P (125 mg once daily, days1-21 of a 28-day cycle) or placebo in combination with TAM (20 mg once daily, continuously). Pre/perimenopausal women should receive concurrent ovarian function suppression with goserelin. Randomization will be stratified by prior ET for advanced/metastatic BC (1st line ET vs. 2nd line ET) and menopausal status (pre/perimenopausal vs. postmenopausal).

KEY ELIGIBILITY CRITERIA:
Eligible patients include women of any menopausal status with HR-positive, HER2-negative advanced or metastatic BC; candidates to receive TAM as 1st line or 2nd line ET for advanced/metastatic disease; ≥18 years of age; measurable or non-measurable disease (RECIST v.1.1); ECOG performance status 0-1; adequate organ function; have not received treatment with TAM (except for patients who have had more than 12 months from completion of adjuvant therapy with TAM); and have not received any CDK4/6 or phosphoinositide 3-kinase (PI3K) - mammalian target of rapamycin (mTOR) inhibitors.

SPECIFIC AIMS:
The primary endpoint is PFS as assessed by the investigator. Secondary endpoints include overall survival (OS), 1, 2, and 3-year survival probabilities, objective response (OR), duration of response, clinical benefit rate (CBR), pharmacokinetics, safety, and patient-reported outcomes.

STATISTICAL METHODS:
The sample size was determined to detect a 38% reduction in the hazard of disease progression or death in P plus TAM arm with a 1-sided significance level of 2.5% and power of 80%. A stratified log rank test will be used to compare PFS between the 2 treatment arms.

PRESENT ACCRUAL AND TARGET ACCRUAL:
Target accrual of 180 patients will be enrolled within 23 sites among Japan, Korea, Taiwan, and Singapore. As of June 2018, 46 patients have been enrolled.

CONTACT INFORMATION:
This trial is registered at ClinicalTrials.gov NCT03423199 and UMIN000030816. For more information, email NCCH1607_office@ml.res.ncc.go.jp
IMMUNe mOdulation in early stage estrogen receptor positive breast cancer treated with neoADjuvant Avelumab, Palbociclib, and Tamoxifen: The ImmunoADAPT study (NCT03573648)

Cesar A Santa-Maria, Chenguang Wang, Ashley Cimino-Mathews, Evanthia Roussos-Torres, Roisin M Connolly, Antonio C Wolff, Elizabeth M Jaffee and Vered Stearns. 1Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD.

Background:
While some patients with early stage endocrine receptor positive (ER+) breast cancer experience excellent prognosis, a subset of patients with more aggressive phenotypes still have a high rate of recurrence despite optimal adjuvant endocrine therapy and chemotherapy, thus novel therapies are needed for patients with high risk disease.

Although immune checkpoint blockade has shown significant benefit in numerous types of cancer, initial reports demonstrate low response rates to single agent programmed cell death ligand 1 (PD-L1) inhibition in ER+ breast cancer. Inhibitors of cyclin dependent kinases (CDK) 4 and 6 in combination with endocrine therapy are highly active in breast cancer, and recently have been demonstrated to recruit immune cells, and increase PD-L1 on tumor cells in preclinical models. Increased tumor infiltrating lymphocytes (TILs) has been observed with neoadjuvant treatment with CDK4/6 inhibitors in patients with ER+ breast cancer. We thus hypothesize that the addition of palbociclib (CDK4/6 inhibitor) will improve responses to avelumab (PD-L1) inhibitor in patients with high risk ER+ breast cancer.

Trial Design:
Eligible participants are those stage II or III ER+HER2- breast cancer (T2N0 must have ≥ grade 2, T1N+ must have at least a 1.5cm breast primary). Patients will undergo a baseline MRI and biopsy, start tamoxifen +/- palbociclib for 1 cycle (1 cycle = 28 days), and then undergo a repeat MRI and biopsy. Avelumab will be added to both arms in cycle 2. Patients will be treated for 3 cycles of avelumab with tamoxifen +/- palbociclib (thus 4 cycles total, including run-in without avelumab). Patients will be treated as long as there is no evidence of progression and therapy is tolerated, and then undergo MRI and surgery. The primary objective is to determine the clinical complete response (cCR) rate by MRI. Secondary objectives include evaluation of TILs (H&E), CD8 and FOXP3 by immunohistochemistry (IHC), T cell receptor (TCR) repertoire (TCR sequencing), multiplex gene expression panel (Nanostring), and multiplex IHC. Changes in these immune biomarkers will be assessed to determine differential immunophenotypic effects of palbociclib, and correlated to cCR in each arm.

The sample size of this pilot study is determined by primary analysis on the cCR rate. We hypothesize that the addition of palbociclib to tamoxifen will result in an increase rate of cCR in patients receiving avelumab. We hypothesize that the addition of avelumab will increase the response rate to palbociclib and tamoxifen by 30%. We thus estimate that a total of 40 evaluable patients (20 to each arm) will provide close to 80% power to detect a difference on cCR rates of 10% vs 40% at two-sided alpha level 10%. We will evaluate and compare cCR rates between arms by conducting Fisher's Exact test and reporting the estimated proportions together with their exact confidence intervals. Logistic regression analysis will also be conducted to explore the association between cCR and immune biomarkers.

This study has received IRB approval and is open as of Summer 2018.
Selecting the optimal position of CDK4/6 inhibitors in hormone-receptor-positive advanced breast cancer: The BOOG 2017-03 SONIA study

Annemiek van Ommen - Nijhof, Anna van der Voort, Inge R Konings, Agnes Jager, Gabe S Sonke, On behalf of the SONIA Investigators (SONIA Steering Committee) and And the Dutch Breast Cancer Research Group (BOOG). The Netherlands Cancer Institute, Amsterdam, Netherlands; Amsterdam UMC, Amsterdam, Netherlands; Erasmus MC Cancer Institute, Rotterdam, Netherlands; SONIA Steering Committee, Amsterdam, Netherlands and Dutch Breast Cancer Research Group (BOOG), Amsterdam, Netherlands.

BACKGROUND
Combining cyclin-dependent kinases 4 and 6 (CDK4/6) inhibitors with endocrine therapy (ET) is an effective strategy to improve progression-free survival (PFS) in hormone receptor-positive (HR+), human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer (ABC). There is a lack of comparative data to help clinicians decide whether CDK4/6 inhibitors can best be added to first- or second-line ET. The former strategy may provide longer PFS benefit, but is associated with longer use of the drug, which results in more toxicity and costs, whereas no clear benefit on overall survival (OS) or quality of life (QoL) has been proven thus far. No predictive biomarker exists to select patients who are most likely to benefit from the addition of CDK4/6 inhibition.

TRIAL DESIGN AND AIMS
The SONIA study is an investigator-initiated, multicenter, randomized phase III study, funded by ‘ZonMw’ and ‘Zorgverzekeraars Nederland’. Patients are randomly assigned to receive either strategy A (first-line treatment with a non-steroidal aromatase inhibitor (NSAI) + CDK4/6 inhibition, followed on progression by fulvestrant) or strategy B (first-line treatment with NSAI, followed on progression by fulvestrant + CDK4/6 inhibition). Each CDK4/6 inhibitor can be used according to its approved EMA label. The primary objective is to test whether strategy A is superior to strategy B. The primary endpoint is time from randomization to second objective progression (PFS2). Secondary endpoints include OS, safety, QoL, and cost-effectiveness. Additional biomarker analyses will be performed to optimize patient selection.

ELIGIBILITY CRITERIA
Patients with a proven diagnosis of HR+/HER2-negative advanced breast cancer without prior systemic therapy for advanced disease who are candidates to receive NSAIs as first-line treatment, are eligible for the study. Exclusion criteria include advanced visceral spread with the risk of life-threatening complications in the short term. Other conditions excluding a patient from participating are other malignancies, prolonged QTc time (>480ms) or any other medical condition that interferes with study procedures or compliance.

STATISTICAL METHODS
The difference in PFS2 will be estimated using the intention-to-treat population in a Cox proportional hazards model accounting for all stratification factors (visceral versus non-visceral disease, yes versus no prior ET in (neo)adjuvant setting, hospital, and type of CDK4/6 inhibitor). Five-hundred seventy-four primary outcome events yield 89% power to show that strategy A has statistically significant, clinically meaningful (according to European Society for Medical Oncology - Magnitude of Clinical Benefit Scale) superior PFS2 in a log-rank test at the two-sided 95% confidence level.

ACCRUAL
TARGET: with an accrual period of 42 months and an additional 18 months follow-up, inclusion of 1050 evaluable patients is required. A total of 76 Dutch hospitals will participate.
PRESENT: the study is open in 51 hospitals and 106 patients are included.
Background: Dysregulation of cyclin D-CDK4/6-Rb pathway is associated with endocrine resistance in hormone receptor–positive (HR+) breast cancer. Recently, a CDK4/6 inhibitor has shown unprecedented efficacy in metastatic disease, leading to its regulatory approval. Several others are currently in clinical development for the management of HR+ breast cancer in the early and advanced settings. However, it is vital to gain insights into the molecular and biological effects of this class of agents and could identify patients who can benefit the most, delaying or avoiding the use of chemotherapy. The neoadjuvant setting provides an ideal scenario to carry out these investigations. Hence, we propose to conduct an exploratory study to evaluate the biological effects and the efficacy of ribociclib in patients with primary luminal B tumors. We hypothesize that the combination of ribociclib plus letrozole may offer clinical benefit in the preoperative setting.

Methods: This is a parallel, multicenter, two-arm, randomized exploratory study in postmenopausal women with primary operable HR+/HER2-negative Luminal B breast cancer designed to evaluate the clinical benefit of ribociclib plus letrozole. Eligibility includes stage I-III operable breast cancer, Luminal B by PAM50, ECOG 0-1. They will be randomized 1:1 to receive either six 28-days cycles of ribociclib (600mg; 3-weeks-on/1-week-off) plus daily letrozole (2.5mg) or chemotherapy: four cycles of AC (doxorubicin 60 mg/m2, cyclophosphamide 600 mg/m2 every 21 days) followed by weekly paclitaxel during 12 weeks. Baseline, Day 15 on-treatment, and surgical specimens will be collected for molecular characterization and evaluation of response (decrease in Ki67, change to ROR low disease). The primary endpoint is the rate of Residual Cancer Burden (RCB) per MD Anderson Cancer Center procedures. A rate of RCB 0 and 1 score at surgery, with a rank between 20% to 25% with 47 evaluable patients by group of treatment will offer a precision between 11.5% and 12.4%, respectively (95%CI). Ninety-four patients will be enrolled in 21 sites across Spain. The trial was activated in July 2017. As of June 2018, 78 patients have been recruited.
Utilizing multiomic advanced diagnostics to identify CDK4/6 inhibitor response predictors and a post-treatment multiomic signature for patients with ER+/HER2- metastatic breast cancer (SIDEOUT-3)

Maysa M Abu-Khalaf1, Mariaelena Pierobon2, Neelima Denduluri3, Frances Valdes-Albini4, Andres Forero-Torres5, Amy Clark6, Rachel Yung7, Monica Mita8, Stephani Christensen9, Kris Awerkamp10, Bryant Dunetz11, Rita Murphy1, Christos Hatzis12, Daniel Zelterman12, Lance Liotta2 and Emanuel Petricoin2.

1Sidney Kimmel Cancer Center at Jefferson, Philadelphia; 2George Mason University, Fairfax; 3Virginia Cancer Specialists, Arlington; 4University of Miami, Miami; 5University of Alabama, Birmingham; 6University of Pennsylvania, Philadelphia; 7University of Washington, Seattle; 8Cedars-Sinai, Los Angeles; 9Comprehensive Cancer Centers of Nevada, Henderson; 10TD2, Scottsdale; 11Side Out Foundation, Fairfax and 12Yale University, New Haven.

Background: Palbociclib, ribociclib and abemaciclib are 3 cyclin-dependent kinase (CDK) 4/6 inhibitors (inh) approved by the FDA for treatment of patients (pts) with hormone receptor–positive (HR+) metastatic breast cancer (MBC). We hypothesize that measuring the signaling architecture of CDK 4/6 kinase signaling network will predict response to CDK 4/6 inh and identify pts who are unlikely to respond to CDK4/6 inh and can be treated with other FDA approved drugs or a clinical trial. Patients who develop disease progression on CDK 4/6 inh within 12 months of starting therapy are eligible for a unique multi-omic based molecular analysis that can be used as a therapeutic decision support tool.

Trial design: This is an open label, multicenter study prospectively evaluating the phosphoprotein-based CDK 4/6 kinase network within the tumors of 100 pts with HR + MBC who are candidates for standard 1st line treatment with a CDK 4/6 inh plus endocrine therapy (ET). Eligible pts must have pretreatment tissue from a metastatic lesion sufficient to complete baseline biomarker analysis using a novel Laser Capture Microdissecton (LCM) reverse phase protein array (RPPA) coupled approach to quantitatively analyze 8 specific proteins/phosphoproteins within the CDK 4/6 kinase signaling network (Total Rb; phospho Rb (S780); total Cyclin D1; phospho Cyclin D1 (S286); total p16INK; total p27KIP; phospho27KIP (T187); phosphoFoxM1 (T600). Pts who develop disease progression within 12 months of starting CDK4/6 inh plus ET will be eligible for an optional biopsy of a soft tissue or bone metastatic lesion at time of disease progression for molecular analysis using a multi-omic CAP/CLIA laboratory assays to analyze post-therapy biopsies by RPPA, IHC analysis, RNA-Seq, and targeted exome sequencing. A molecular tumor board then provides the results to the treating physician as a therapeutic decision support tool outlining potential targets and possible therapies which may be used for further treatment. The primary objective is to demonstrate a correlation between one-year progression-free survival (PFS) and pre-treatment phospho RB levels. Secondary endpoints will examine the association between one-year PFS and 7 pre-specified CDK 4/6 signaling network markers. Thirteen of planned 100 patients have been enrolled. The study will be conducted at 12 centers.

Clinical trial registry number 03195192
PATINA: A randomized, open label, phase III trial to evaluate the efficacy and safety of palbociclib + anti-HER2 therapy + endocrine therapy (ET) vs. anti-HER2 therapy + ET after induction treatment for hormone receptor positive (HR+)/HER2-positive metastatic breast cancer (MBC)

Otto Metzger1, Sumithra Mandrekar2, Sibylle Loibl3, Christoph Mundhenke4, Sabine Seiler2, Pinuccia Valagussa5, Elgene Lim6, Debu Tripathy7, Eric P Winer1, Cynthia Huang8, Lisa Carey9, Prue Francis10, Kathy Miller11, Matthew P Goetz12, Aleix Prat13, Sherene Loi14, Ian Krop1, Luca Gianni15, Suzette Delalogue17, Ines Vaz-Luis17, Travis Dockter2, Jane Lanzillotti18, Eva Ciruelos16 and Angela M DeMichele19. 1Dana Farber Cancer Institute, Boston; 2Mayo Clinic AFT SDC, Rochester; 3German Breast Group, Neu-Isenburg, Germany; 4Universitätsklinikum Schleswig-Holstein, Kiel, Germany; 5Fondazione Michelangelo, Milan, Italy; 6Garvan Institute, Sydney, Australia; 7MD Anderson Cancer Center, Houston; 8Pfizer, New York; 9University of North Carolina, Chapel Hill; 10Peter MacCallum Cancer Center, Melbourne, Australia; 11Indiana University Simon Cancer Center, Indianapolis; 12Mayo Clinic, Rochester; 13Medical Oncology, Hospital Clinic, Barcelona, Spain; 14Translational Breast Cancer Genomics Lab, Peter MacCallum Cancer Center, Melbourne, Australia; 15Medical Oncology, IRCCS San Raffaele, Milan, Italy; 16University Hospital 12 de Octubre, Madrid, Spain; 17UNICANCER, Paris, France; 18Alliance Foundation Trials, LLC, Boston and 19University of Pennsylvania-Perelman Center for Advanced Medicine, Philadelphia.

Background:
Pre-clinical data and results from early phase clinical trials point to synergistic antitumor activity and potential efficacy of palbociclib when given in combination with anti-HER2 therapy (tx). The aim of PATINA is to determine the effect of adding palbociclib to anti-HER2 and ET maintenance after induction tx in the 1st line setting for HR+/HER2+ MBC.

Trial Design:
The PATINA trial (AFT-38/NCT02947685) is a pivotal, open-label, international, phase III study. Following 6-8 cycles of chemotherapy (taxane or vinorelbine) with anti-HER2 tx for MBC participants will be randomized 1:1 to standard anti-HER2 tx (trastuzumab +/- pertuzumab) in combination with ET with or without palbociclib until disease progression. ET options are either an aromatase inhibitor or fulvestrant. Premenopausal patients (pts) must receive ovarian suppression. The trial is open to men or women with histologically confirmed HR+/HER2+ MBC provided they are without evidence of disease progression by local assessment after induction tx. Total planned accrual is 496 pts. Primary objective is to demonstrate that the combination of palbociclib with anti-HER2 tx plus ET is superior to anti-HER2 tx plus ET alone in prolonging progression-free survival (PFS). Key secondary objectives are measures of tumor control, overall survival, safety and Quality of Life. The main translational science objective is to compare PFS estimates according to PIK3CA mutation status. The study has a 90% power to detect a hazard ratio of 0.667 in favor of the palbociclib arm. All pts approached to participate in PATINA will be asked to share remaining biospecimens and clinical data with the Mastering Breast Cancer Initiative. This initiative was created in order to understand the natural history of MBC and how it envolves over time with the aim to develop new treatments for this patient population. Recruitment has started in 07/2017 and is planned for approximately 22 months in 140 sites in Australia, Germany, Italy, France, New Zealand, Spain, and the US. 69 pts have been recruited so far.

The study is sponsored by Alliance Foundation Trials (AFT) and financially supported by Pfizer.
Genetic analysis in blood, urine, stool and tumor samples from patients with advanced or metastatic estrogen receptor positive and HER2 negative breast cancer receiving palbociclib and endocrine therapy (PROMISE)

Ciara C O’Sullivan¹, Vera J Suman¹, Krishna R Kalari¹, Ann Moyer¹, Jaeyun Sung¹, Alvaro Moreno-Aspitia², Donald W Northfelt³, Minetta C Liu¹, Tufia C Haddad¹, Saranya Chumsri², Fergus J Couch¹, Richard M Weinshilboum¹, Liewei Wang¹ and Matthew P Goetz¹. ¹Mayo Clinic, Rochester, MN; ²Mayo Clinic, Jacksonville, FL and ³Mayo Clinic, Scottsdale, AZ.

**Background:** Combining cyclin dependent 4/6 kinase inhibitors (CDK4/6i) with endocrine therapy (ET) has resulted in clinically significant improvements in progression-free survival (PFS) in persons with hormone-receptor (HR)-positive metastatic breast cancer (MBC). However, nearly all patients will progress on CDK4/6i and ET and the mechanisms associated with primary and secondary resistance are mostly unknown. The identification of biomarkers associated with response to CDK4/6i is therefore a major research priority. PROMISE is a multicenter prospective cohort study designed to perform a comprehensive “omic” assessment of blood, tumor, urine and the fecal microbiome to identify alterations in molecular or cellular features associated with primary endocrine resistance (e.g. disease progression ≤ 12 months on treatment) and acquired resistance to CDK4/6i. Additionally, patient derived xenografts (PDX) and organoids are generated to test new drug strategies designed to reverse resistance to CDK4/6i and ET. **Methods:** Eligible participants include women for whom palbociclib is recommended in combination with either letrozole (first-line) or fulvestrant (second-line) therapy for HR-positive MBC. As of July 2018, 14 patients have been enrolled; the target accrual is 250 patients, who will be followed over the course of 36 months and followed for at least 12 months after the close of enrollment. Blood and tumor biopsies are obtained at baseline, at the end of cycle 2, and at progression. Whole exome sequencing (germline and tumor) and RNAseq (whole transcriptome) are performed on tumor samples in a CAP/CLIA lab (TEMPUS) and results will be provided back to all patients for later use. Additionally, PDX and organoids are generated from tumor biopsies at baseline and during progression. Blood, stool, and urine samples are collected for additional correlative studies. The primary objective of this trial is to identify novel genomic variants and pathways associated with early progression (≤ 12 months) among women with advanced HR-positive breast cancer treated with palbociclib and ET. Secondary objectives include identification of the biomolecular features within the gut (stool) microbiome and exploration of the metabolomics and proteomics of ER-positive MBC. Results from the interrogation of these biospecimens will be critical to gain insights into treatment resistance. Funding is provided by Mayo Clinic Center for Individualized Medicine, TEMPUS, and an ASCO Career Development Award (COS). ClinicalTrials.gov Identifier: NCT03281902.
Open-label, single-arm study evaluating the antitumor activity and safety of niraparib as neoadjuvant treatment in patients with localized, HER2-negative, BRCA-mutant breast cancer

Hyo Han¹, Erika Hamilton², Hanna Irie³, Steven Isakoff⁴, Danijela Jelovac⁵, Andre Liem⁶, Minetta C Liu⁷, Adrianna Milillo⁸, Julie Nangia⁹, David Page¹⁰, James Reeves¹¹, Cesar Santa-Maria⁵, Meghan Duncan¹², Julie R Graham¹², Jian Chen¹², Bruce J Dezube¹² and Laura Spring*. ¹Moffitt Cancer Center-McKinley Outpatient Clinic, Tampa, FL; ²Tennessee Oncology, Nashville, TN; ³Icahn School of Medicine at Mount Sinai, New York, NY; ⁴Massachusetts General Hospital, Boston, MA; ⁵Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; ⁶Pacific Shores Medical Group, Long Beach, CA; ⁷Mayo Clinic Rochester, Rochester, MN; ⁸Memorial Health Care System, Hollywood, FL; ⁹Baylor College of Medicine, Houston, TX; ¹⁰Providence Portland Medical Center, Portland, OR; ¹¹Florida Cancer Specialists-South, Fort Myers, FL and ¹²TESARO, Inc., Waltham, MA.

**Background:** Neoadjuvant chemotherapy is administered to patients with operable breast cancer to downstage the tumor to allow for less extensive surgery and to provide prognostic information about drug efficacy and risk of disease recurrence. Patients who achieve a pathological complete response (pCR) following neoadjuvant treatment have a more favorable outcome than patients with residual invasive disease. Single-agent poly(ADP-ribose) polymerase (PARP) inhibitors have clinical efficacy in BRCA-mutated breast cancer. Niraparib, a potent and selective PARP1/2 inhibitor, is approved for maintenance treatment of patients with recurrent ovarian cancer and has demonstrated strong antitumor activity in in vivo studies with BRCA1-mutant breast cancer. The objective of this study is to evaluate the antitumor activity of single-agent niraparib in the neoadjuvant treatment of patients with localized, human epidermal growth factor receptor 2 (HER2)-negative, BRCA-mut breast cancer.

**Trial Design:** This is an open-label, single-arm pilot study with a target enrollment of 20 evaluable patients. Eligible patients are those ≥18 years old with histologically-confirmed HER2-negative localized breast cancer and either a BRCA1 or BRCA2 mutation (germline or somatic) and no prior anti-cancer therapies for the current malignancy. Patients will receive 200 mg of oral niraparib once daily for 2 months, after which they may either proceed directly to surgery or receive chemotherapy at the discretion of the physician. The primary endpoint is tumor response rate based on the change in tumor volume as measured by breast MRI after 2 months of treatment with niraparib; a response is defined as ≥30% reduction of tumor volume from baseline. Secondary endpoints include pCR rate, tumor response rate based on the change in tumor volume as measured by breast ultrasound, and safety and tolerability. Data will be summarized in a descriptive nature by frequency distributions (number and percentage of patients) for categorical variables and by the mean, median, and standard deviation for continuous variables. Tumor response rate will be tabulated together with its 95% binomial exact confidence interval.

**Funding:** TESARO, Inc., Waltham, MA, USA sponsored the study.
A phase 2, open-label, single-arm, multi-center study of talazoparib for neoadjuvant treatment of germline \textit{BRCA1/2} mutation patients with early-stage triple-negative breast cancer (TNBC)

Jennifer Litton\textsuperscript{1}, Fraser Symmans\textsuperscript{1}, Keerthi Gogineni\textsuperscript{2}, Marc Saltzman\textsuperscript{3}, Melinda L Telli\textsuperscript{4}, Lydia Usha\textsuperscript{5}, Jayeta Chakrabarti\textsuperscript{6}, Iulia Cristina Tudor\textsuperscript{7}, Ruben GW Quek\textsuperscript{7} and Akos Czibere\textsuperscript{8}. \textsuperscript{1}MD Anderson Cancer Center, Houston, TX; \textsuperscript{2}Emory University – Winship Cancer Institute (WCI), Atlanta, GA; \textsuperscript{3}Innovative Medical Research of South Florida, Aventura, FL; \textsuperscript{4}Stanford University School of Medicine, Stanford, CA; \textsuperscript{5}Rush University Medical Center, Chicago, IL; \textsuperscript{6}Pfizer Ltd, Surrey, United Kingdom; \textsuperscript{7}Pfizer, Inc., San Francisco, CA and \textsuperscript{8}Pfizer, Inc., Cambridge, MA.

**Background:** Approximately 15\% of all breast cancers are triple negative and deleterious \textit{BRCA1/2} mutations are found in ~11\% of unselected TNBC. In the phase 3 EMBRACA trial (NCT01945775), the poly (ADP-ribose) polymerase (PARP) inhibitor talazoparib was superior to chemotherapy in prolonging progression-free survival in \textit{BRCA1/2} mutation patients with advanced breast cancer. A recent pilot study (NCT02282345) of 20 patients, explored the feasibility of neoadjuvant talazoparib in \textit{BRCA1/2} mutation patients; pathologic complete response (pCR) was reported at 53\% with 6 months of single agent talazoparib.

**Trial Design:** This phase 2, single-arm, open-label, multi-center study has a Simon 2-stage design. Eligible pts have stage I-III invasive TNBC (ER and PR <10\%), with germline \textit{BRCA1/2} mutations who are suitable for neoadjuvant therapy. Pts will receive talazoparib 1 mg daily for 24 weeks, followed by breast surgery, which should occur within 4 to 6 weeks of the last dose. Ultrasound will be performed serially to assess tumor response. The primary objective is to evaluate pCR after 24 weeks of neoadjuvant talazoparib. Pts will be followed for at least 5 years to assess long term outcomes (event-free and overall survival). After surgery, any further adjuvant therapy will be given at the discretion of the treating physician. Pt reported outcomes will be assessed electronically including the global health status/quality of life, functions, and symptoms using the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaires C30 and BR23. Plasma pharmacokinetic (PK) samples for determination of talazoparib concentrations will be collected at defined timepoints to describe the steady-state PK of talazoparib. Exploratory biomarker research will also take place. Approximately 122 men and women will be enrolled in the study, of which 112 evaluable pts are planned. With 112 evaluable pts and one interim futility look, the null hypothesis that the true pCR rate is 35\% will be tested against a 1-sided alternative. This design yields a 1-sided type 1 error rate of 2.5\% and power of 90\% when the true pCR rate is 50\%. An interim analysis will be performed to evaluate the efficacy of talazoparib after 28 evaluable pts undergo talazoparib treatment for 24 weeks, followed by surgery, and are assessed for pCR by central review. This trial is currently recruiting and is registered at clinicaltrials.gov (NCT03499353).

**Funding:** This study is sponsored by Pfizer, Inc.
PARTNER: Randomised, phase II/III trial to evaluate the safety and efficacy of the addition of olaparib to platinum-based neoadjuvant chemotherapy in triple negative and/or germline BRCA mutated breast cancer patients

Jean Abraham¹, Anne-Laure Vallier², Wendi Qian², Andrea Machin², Louise Grybowicz², Stanly Thomas², Melanie Weiss², Caron Harvey², Karen McAdam², Luke Hughes-Davies², Anne Roberts³, Rebecca Roylance³, Ellen Copson⁴, Karen Pinilla¹, Anne Armstrong⁵, Elena Provenzano², Marc Tischkowitz¹, Emma McMurty⁶ and Helena Earl¹,⁷. ¹University of Cambridge, Cambridge, United Kingdom; ²Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; ³University College London, London, United Kingdom; ⁴University of Southampton, Southampton, United Kingdom; ⁵The Christie NHS Foundation Trust, Manchester, United Kingdom; ⁶Astra Zenecca, Macclesfield, United Kingdom and ⁷NIHR Cambridge Biomedical Research Centre, Cambridge, United Kingdom.

Background: No specific targeted therapies are available for Triple Negative Breast Cancers (TNBC), an aggressive and diverse subgroup. The basal TNBC sub-group share some phenotypic and molecular similarities with germline BRCA (gBRCA) tumours. In gBRCA patients, and potentially other homologous recombination deficiencies, these already compromised pathways may allow drugs called PARP inhibitors (Olaparib) to work more effectively. Aims: To establish if the addition of olaparib to neoadjuvant platinum based chemotherapy for basal TNBC and/or gBRCA breast cancer is safe and improves efficacy (pathological complete response (pCR)).

Methods: Trial design: 3-stage open label randomised phase II/III trial of neoadjuvant paclitaxel and carboplatin +/- olaparib, followed by clinicians’ choice of anthracycline regimen. Stage 1 and 2: Randomisation (1:1:1) to either control (3 weekly carboplatin AUC5/weekly paclitaxel 80mg/m² for 4 cycles) or one of two research arms with the same chemotherapy regimen but with two different schedules of olaparib 150mg BD for 12 days. Stage 3: Patients are randomised (1:1) to either control arm or to the research arm selected in stage 2. End-points: Stage 1: Safety; Stage 2: Schedule selection using pCR rate and completion rate of olaparib using a “pick-the-winner” design. Stage 3: pCR rate. Enrichment design is applied with an overall significance level 0.05(α) and 80% power. A total of 527 patients will be included to detect an absolute improvement of 15% (all patients) and 20% (gBRCA patients) by adding olaparib to platinum based chemotherapy.

Trial Progress: PARTNER has been recruiting in UK since 27th May 2016. IDSMC recommended to continue the trial without change after reviewing the Stage 1 safety data. The recruitment of stage 2 was completed in April 2018 and results to be reviewed by the IDSMC in early 2019. The trial is open and enrolling patients to national and international sites.
Nivolumab or capecitabine or combination therapy as adjuvant therapy for triple negative breast cancer (TNBC) with residual disease following neoadjuvant chemotherapy: The OXEL study

Katia Khoury¹, Claudine Isaacs¹, Margaret E Gatti-Mays², Renee N DoNahue², Jeffrey Schlom², Hongkun Wang³, Christopher Gallagher¹, Deena Graham⁵, Robert Warren¹, Asma Dilawari¹/⁴, Sandra M Swain¹, Paula R Pohlmann¹ and Filipa Lynce¹.
¹Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC; ²National Cancer Institute, National Institute of Health, Bethesda, MD; ³Georgetown University Medical Center, Washington, DC; ⁴Washington Cancer Institute, MedStar Washington Hospital Center, Washington, DC and ⁵Hackensack University Medical Center, Hackensack, NJ.

Background: Long-term follow-up of neoadjuvant studies demonstrates poor clinical outcomes in patients with TNBC who do not achieve pathologic complete response, with only 35% remaining free of recurrence at 10 years. The addition of adjuvant capecitabine in the CREATE-X study prolonged disease free survival and overall survival (OS) in patients with HER2 negative breast cancer with residual invasive disease, with more striking benefit in patients with TNBC. Checkpoint inhibitors have not been approved in breast cancer yet, but recent studies suggest a benefit in combination with chemotherapy and low burden of disease. In the current study, we will evaluate the role of chemoimmunotherapy in the adjuvant setting for patients with TNBC with residual disease after neoadjuvant therapy. We will also investigate the role of the peripheral immunoscore (PIS) in predicting the benefit of immune checkpoint inhibition with or without chemotherapy.

Trial design: OXEL is a pilot open-label three arm randomized study of nivolumab, capecitabine or the combination as adjuvant therapy for 45 patients with residual TNBC after adequate neoadjuvant chemotherapy. Patients enrolled will be randomly assigned to 1 of 3 treatment arms: nivolumab 360 mg iv q3weeks for x 6 cycles; capecitabine 1250mg/m² po bid D1-D14 q3 weeks x 6 cycles; nivolumab 360mg iv q3weeks + capecitabine 1250mg/m² po bid D1-D14 q3 weeks x 6 cycles.

Main eligibility criteria: Patients ≥18 years of age with TNBC and ≥1cm of residual disease in the breast and/or node positive disease; receipt of neoadjuvant taxane +/- anthracycline, or platinum, and having completed definitive resection of primary tumor, with no prior use of capecitabine, fluorouracil or immunotherapy, and with no active autoimmune disease or chronic use of systemic steroids.

Specific aims: The primary endpoint is assessing the immunologic effects of capecitabine, nivolumab or the combination in the adjuvant setting by PIS. Additional endpoints include toxicity assessment, distant recurrence free survival (DRFS) and OS at 3-years, association between changes in PIS and circulating tumor DNA at different timepoints with clinical outcome variables and characterization of the immune contexture in residual tumors.

Statistical methods: The study is designed to assess the change in PIS at 6 weeks from baseline in each arm. The sample size of 15 per arm (45 total for 3 arms) will provide preliminary results. A sample size of 15 per arm will have 85% power to detect an effect size of 1 (the difference of the change in PIS from baseline to week 6 between two arms divided by the standard deviation) at 5% significance level.

Present accrual and target accrual: The Institutional Review Board at Georgetown University Medical Center has approved the study. Clinicaltrials.gov NCT03487666. Enrollment of the first patient is expected in July 2018 with a total of 45 patients planned to be recruited. Recruitment sites are MedStar Georgetown University Hospital, MedStar Washington Hospital Center, Hackensack University Medical Center. This trial is supported by Bristol-Meyers Squibb, P30CA051008-25 from NCI, Inivata and the Nina Hyde Center for Breast Cancer Research.
Neoadjuvant Her2-targeted therapy +/- immunotherapy with pembrolizumab (neoHIP): An open label randomized phase II trial

Heather L McArthur1, Jorge Henrique S Leal1,2, Christina DiLauro Abaya1, Reva Basho1, Hannah Coleman1, Stephen Shiao1, Simon Knott1, Mourad Tighiouart1, Farnaz Dadmanesh1, Armando Giuliano1 and Sunil Verma3. 1Cedars-Sinai Medical Center, Los Angeles, CA; 2CLION - CAM Group, Salvador, Bahia, Brazil and 3University of Calgary, Calgary, AB, Canada.

**Background:** In preclinical models HER2-directed therapy administered with checkpoint blockade is synergistic. Clinically, trastuzumab administered with pembrolizumab-mediated checkpoint blockade in trastuzumab-resistant HER2-positive metastatic breast cancer was safe and demonstrated modest activity. However, because checkpoint blockade can confer improved responses when administered earlier in the course of disease, trastuzumab with pembrolizumab administered in the curative-intent, treatment-naive setting may confer life-long, tumor-specific immunity and ultimately, improve cure rates. Moreover, the potential synergy of trastuzumab and pembrolizumab with paclitaxel may overcome the need for dual HER2-blockade. The neo-HIP study is a randomized, multicenter, phase II, open-label trial to evaluate the efficacy and safety of weekly paclitaxel, trastuzumab plus pertuzumab (THP) vs weekly THP plus pembrolizumab (THP-K) vs a HER2 monotherapy regimen (TH-K) as neoadjuvant treatment in patients with HER2-positive early stage invasive breast cancer.

**Methods:** Patients ≥18 years old with previously untreated, non-metastatic, stage II-III, HER2-positive (by ASCO/CAP guidelines) breast cancer are eligible. Patients with inflammatory breast cancer or bilateral primary tumors are excluded. Adequate organ function and ECOG PS 0-1 are required. Approximately 174 patients will be randomly assigned to 1 of 3 arms with stratification by clinical nodal status (positive vs. negative) and hormone receptor status (positive vs. negative). In arm A, patients will receive T at 80mg/m2 weekly for 12 weeks, H at 8mg/Kg (1 loading dose) and then 6mg/Kg IV every 3 weeks x 3 doses, P at 840mg (1 loading dose) and then 420mg/Kg IV every 3 weeks x 3 doses (THP). In arm B, patients will receive the same regimen as arm A with the addition of pembrolizumab 200mg IV every 3 weeks x 4 doses (THP-K). In arm C, patients will receive the same regimen as arm B, but without pertuzumab (TH-K). Definitive surgery will be 3-6 weeks after the last treatment dose. After surgery, patients in all arms will be treated per the treating physician's discretion. After completion of post-operative chemotherapy, patients will receive radiotherapy per local clinical standard and those patients whose tumors are hormone-receptor positive will receive hormone therapy as per local standard-of-care. The purpose of this phase II study is to identify whether Arm B (THP-K) and/or Arm C (TH-K) demonstrate a clinically significant improvement in pCR rate when compared with Arm A (THP). The primary end point is pCR rate in the breast and axilla (ypT0/Tis ypN0). Secondary end points include pCR rate by ypT0/ypN0 and ypT0/Tis, residual cancer burden index, event free survival, breast conserving surgery rate, safety and overall survival. Exploratory correlative studies will characterize the immunologic responses to the interventions and explore potential predictors of efficacy and toxicity.
KEYNOTE-756: A randomized, double-blind, phase III study of pembrolizumab versus placebo in combination with neoadjuvant chemotherapy and adjuvant endocrine therapy for high-risk early-stage ER+/HER2- breast cancer

Fatima Cardoso¹, Aditya Bardia², Fabrice Andre³, David W Cescon⁴, Heather McArthur⁵, Melinda Telli⁶, Sherene Loi⁷, Javier Cortés⁸, Peter Schmid⁹, Nadia Harbeck¹⁰, Carsten Denkert¹¹, Christian Jackisch¹², Liyi Jia¹³, Konstantinos Tryfonidis¹³ and Vassiliki Karantza¹³. ¹Champalimaud Clinical Centre/Champalimaud Foundation, Lisbon, Portugal; ²Massachusetts General Hospital, Harvard Medical School, Boston, MA; ³Faculté de Medicine Paris-Sud XI, Gustave Roussy, Paris, France; ⁴Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada; ⁵Cedars-Sinai Medical Center, Los Angeles, CA; ⁶Stanford University School of Medicine, Stanford, CA; ⁷Peter MacCallum Cancer Centre, University of Melbourne, Melbourne, Victoria, Australia; ⁸Breast Cancer Program, Ramon y Cajal University Hospital, Madrid, Spain; ⁹Centre for Experimental Medicine, Barts Cancer Institute, London, United Kingdom; ¹⁰Breast Center, Ludwig-Maximilian University of Munich, Munich, Germany; ¹¹Institute of Pathology, Charité–Universitätsmedizin Berlin, Berlin, Germany; ¹²Sana Klinikum, Offenbach, Germany and ¹³Merck & Co., Inc., Kenilworth, NJ.

Background: Although ER+/HER2- breast cancer has a better overall prognosis than other breast cancer subtypes, there is a high-risk subpopulation characterized by high-grade tumors and decreased sensitivity to endocrine therapy, higher responsiveness to chemotherapy and worse prognosis. A large meta-analysis of prospective studies focusing on neoadjuvant chemotherapy (NAC) for treatment of stage I-III breast cancer demonstrated that increased pathologic complete response (pCR) rates at surgery were associated with improved survival. This correlation was observed across triple-negative breast cancer (TNBC), HER2+ breast cancer, and high-grade HR+/HER2- breast cancer. Specifically, patients with a pCR after NAC had a 5-year event-free survival (EFS) rate of 90%, whereas patients who did not achieve a pCR had a 5-year EFS rate of 60%. Therefore, increasing pCR rates after NAC may have a substantial impact for patients with high-risk early-stage HR+/HER2- breast cancer. KEYNOTE-756 is a global, randomized, double-blind, phase III study of pembrolizumab (vs placebo) in combination with chemotherapy as neoadjuvant treatment, followed by pembrolizumab (vs placebo) plus endocrine therapy as adjuvant treatment for patients with high-risk, early-stage ER+/HER2- breast cancer.

Methods: Patients with T1c-2 cN1-2 or T3-4 cN0-2 grade 3 or grade 2 with Ki-67 ≥30%, invasive, ductal ER+/HER2- breast cancer who meet the above criteria will be stratified by lymph node involvement (positive vs negative), tumor PD-L1 status (positive vs negative), ER positivity (≥10% vs <10%), and anthracycline dosing schedule (Q3W vs Q2W), and then randomized 1:1 to receive neoadjuvant treatment with pembrolizumab 200 mg Q3W or placebo in combination with paclitaxel (80 mg/m² QW) for 4 cycles followed by (doxorubicin [60 mg/m²] or epirubicin [100 mg/m²]) plus cyclophosphamide (600 mg/m²) Q2/3W for another 4 cycles. After definitive surgery (± radiation therapy, as indicated), patients will receive adjuvant treatment with pembrolizumab (200 mg Q3W) or placebo for 9 additional administrations, in combination with endocrine therapy, which can be given for up to 10 years. Co-primary end points are pCR rate and EFS. Secondary end points are safety and overall survival. The global study will open in North America and Latin America, Europe, and Asia Pacific in the second half of 2018.
A randomized phase II study of pembrolizumab in combination with carboplatin versus carboplatin alone in breast cancer patients with chest wall disease, with immunologic and genomic correlative studies

Neelima Vidula¹, Andrei Goga², Jimmy Hwang³, Minetta C Liu³, Ben H Park⁴, Rita Nanda⁵, Paula R Pohlmann⁶, Anna Maria Storniolo⁷, Adam Brufsky⁸, Vandana Abramson⁹ and Hope S Rugo². ¹Massachusetts General Hospital, Boston, MA; ²University of California, San Francisco, San Francisco, CA; ³Mayo Clinic, Rochester, MN; ⁴Johns Hopkins University, Baltimore, MD; ⁵University of Chicago, Chicago, IL; ⁶Georgetown University, Washington, DC; ⁷Indiana University, Bloomington, IN; ⁸University of Pittsburgh, Pittsburgh, PA and ⁹Vanderbilt University, Nashville, TN.

Background: Thirty percent of patients with breast cancer may experience chest wall recurrence, which is associated with a higher risk of developing distant metastases and a poor prognosis. Cancer cells may evade immune rejection through the programmed cell death 1 (PD-1) pathway. Pembrolizumab, an anti-PD-1 antibody, binds PD-1 and inhibits its interaction with the programmed death ligand 1 (PD-L1) to facilitate tumor immune rejection. We hypothesize that pembrolizumab may be an effective therapy in chest wall recurrence, given the inflammatory nature, and the high expression of PD-1 in tumors with lymphovascular invasion. Platinum agents may enhance anti-tumor immunity in a synergistic manner, and the combination of pembrolizumab and carboplatin has demonstrated efficacy in advanced lung cancer. In this study, the combination of pembrolizumab and carboplatin is being evaluated in breast cancer patients with chest wall disease.

Methods: This is a randomized phase II study of breast cancer patients with advanced, unresectable breast cancer involving the chest wall, being conducted through the Translational Breast Cancer Research Consortium (TBCRC). Patients may have hormone resistant disease (at least 2 prior lines of hormone therapy), triple negative breast cancer, or refractory HER2+ disease for enrollment. They may have other sites of distant metastases, have received any number of prior lines of therapy, have had prior surgery, but prior chest wall radiation is not necessary. Eighty-four patients at 7 TBCRC sites will be randomized 2:1 to treatment with pembrolizumab 200 mg IV and carboplatin AUC 5 IV every 3 weeks followed by pembrolizumab 200 mg IV alone every 3 weeks (Arm A, n=56) or carboplatin AUC 5 IV every 3 weeks (Arm B, n=28), with an option for patients in Arm B to cross-over to single agent pembrolizumab 200 mg IV every 3 weeks (arm Bx) on progression. Patients will undergo imaging with CT chest, abdomen, and pelvis at baseline and every 2 cycles of treatment for response evaluation. The primary endpoint is the disease control rate in the chest wall and distant sites at 18 weeks of treatment, and this study is powered to determine a 20% difference in disease control rates between arms A and B (hazard ratio of 0.52, α= 0.10, β= 0.20). After 18 patients are enrolled into Arm B, an interim analysis for futility will be conducted to enable early closure of that arm for lack of efficacy. Secondary endpoints in the study are toxicity, progression free survival, and response based on PD-L1 expression and irRECIST. Exploratory endpoints, which will be studied using peripheral blood testing and chest wall tumor biopsies at baseline and after 2 cycles of treatment, include determining associations of response with changes in tumor and peripheral blood immune composition, soluble PD-L1 expression, circulating tumor cells, cell free DNA, and tumor PD-L1 and MYC genomic expression. Ultimately this study promises to improve our understanding of checkpoint inhibition and chemotherapy for chest wall disease, and the underlying mechanism of action. This study is open for enrollment and 2 patients are currently enrolled. (NCT03095352).
A randomized double-blind phase III clinical trial of neoadjuvant chemotherapy (NAC) with atezolizumab or placebo in patients (pts) with triple negative breast cancer (TNBC) followed by adjuvant atezolizumab or placebo: NSABP B-59/GBG 96-GeparDouze

Charles E Geyer, Jr.1,2, Sibylle Loibl3, Priya Rastogi1,4, Sabine Seiler3, Joseph P Costantino1,5, Valentina N Nekljudova3, Patricia Cortazar6, Peter C Lucas1,7, Carsten Denkert1,8, Eleftherios P Mamounas1,9, Christian Jackisch3,10 and Norman Wolmark1,11.

1NSABP/NRG Oncology, Pittsburgh; 2Virginia Commonwealth University Massey Cancer Ctr., Richmond; 3German Breast Group (GBG), Neu-Isenburg, Germany; 4McGee-Women's Hospital of UPMC, Pittsburgh; 5University of Pittsburgh, Pittsburgh; 6Genentech, Inc., San Francisco; 7University of Pittsburgh School of Medicine, Pittsburgh; 8Institute of Pathology, Charité - Universitätsmedizin Berlin, Berlin, Germany; 9Orlando Health UF Cancer Center, Orlando; 10Sana Klinikum Offenbach GmbH, Offenbach, Germany and 11Allegheny Health Network Cancer Institute, Pittsburgh.

**Background:**
TNBC is associated with higher percentages of pathological complete response (pCR) to neoadjuvant chemotherapy (NAC), and women with a pCR have a favorable prognosis. However, Liedtke (2008) and Loibl (2017) found that women with residual disease have a substantially higher risk of recurrence than women with other subtypes of breast cancer. Additionally, Adams (2017) and Schmid (2017) found that therapeutic blockade of PD-L1 binding by atezolizumab has resulted in relevant anti-tumor efficacy.

**Methods:**

**Design**
This is a phase III, double blind, placebo-control trial evaluating neoadjuvant atezolizumab with NAC followed by adjuvant atezolizumab in TNBC. Pts are stratified by region (North America; Europe), tumor size (1.1-3.0cm; >3.0cm), AC/EC schedule (q2w; q3w), and nodal status (positive; negative), then randomized 1:1 to receive atezolizumab/placebo 1200 mg IV every 3 wks concurrently with both sequential regimen of weekly paclitaxel 80 mg/m2 IV for 12 doses with every 3-wk carboplatin AUC of 5 IV for 4 doses followed by AC/EC every 2-3 wks (per investigator discretion) for 4 cycles. Following surgery, pts resume atezolizumab/placebo 1200 mg IV every 3 wks as adjuvant therapy for 6 months. Radiotherapy based on local standards is co-administered with atezolizumab/placebo.

**Eligibility criteria**
Centrally-confirmed ER-neg, PR-neg, HER2-neg invasive breast cancer by ASCO/CAP guidelines. Primary tumor must be stage T2 or T3 if cN0 or cN1 with negative biopsy or T1c, T2, or T3 if cN1 with positive biopsy or cN2 or cN3. LVEF >55% and no significant cardiac history.

**Statistical methods**
Co-primary endpoints are event-free survival (EFS) and pCR breast/nodes. Secondary endpoints include pCR breast, overall survival, distant disease-free survival, safety and toxicity. Trial is an academic collaboration between NSABP and GBG with support from Genentech/Roche.

NCT03281954

**Support:** Genentech/Roche
ALEXANDRA/IMpassion030: A phase III study of standard adjuvant chemotherapy with or without atezolizumab in early triple negative breast cancer

Michail Ignatiadis, Heather McArthur, Andrew Bailey, Jorge-Luis Martinez, Evandro De Azambuja, Otto Metzger, Catherine Lai, Noam Ponde, Theodora Goulioti, Fergus Daly, Aicha Bouhlel, Vasiliki Balta, Veerle Van Dooren, Giuseppe Viale, Marion Maetens, Carter Dufrane, Anh Nguyen Duc, Eric Winer, Richard Gelber and Martine Piccart. 1Institut Jules Bordet, Brussels, Belgium; 2Breast International Group, Brussels, Belgium; 3Frontier Science Ltd, Kincraig, United Kingdom; 4Dana-Farber Cancer Institute, Boston; 5Roche, Basel, Switzerland; 6Alliance Foundation Trials, Boston; 7Istituto Europeo di Oncologia, Milan, Italy; 8Genentech, San Francisco and 9Cedars-Sinai Medical Center, Los Angeles.

Background: Triple negative breast cancer (TNBC) is a subtype with a high risk of relapse in the early disease setting. Because TNBC does not currently have specific targeted agents approved for use in the early setting it is treated primarily with chemotherapy. A growing body of evidence indicates that TNBC is more immunogenic than other subtypes of breast cancer and promising clinical activity has been reported with atezolizumab (an anti–PD-L1 antibody) in Phase 1/1b metastatic TNBC trials. Furthermore, the anti-tumor activity of PD-1/PD-L1 targeting drugs is hypothesized to be enhanced when co-administered with chemotherapy. ALEXANDRA/IMpassion030 will evaluate the efficacy and safety of atezolizumab in combination with standard adjuvant chemotherapy in early TNBC.

Methods: ALEXANDRA/IMpassion030 is a global, prospective, randomised, open-label Phase 3 trial investigating the efficacy, safety and pharmacokinetic (PK) profile of adjuvant atezolizumab plus standard chemotherapy versus chemotherapy alone in early TNBC. In total, 2300 patients diagnosed with non-metastatic operable stage II or III TNBC confirmed by central pathology review will be randomised. TumorPD-L1 evaluation will be performed centrally. Patients will be stratified by type of surgery, nodal status, and PD-L1 status. The adjuvant treatment will consist of weekly paclitaxel 80 mg/m² for 12 weeks followed by dose dense anthracycline (epirubicin 90 mg/m² or doxorubicin 60 mg/m²) and cyclophosphamide 600 mg/m² for 4 doses every 2 weeks or the same chemotherapy regimen (T-EC/AC) given concomitantly with atezolizumab 840 mg every 2 weeks followed by maintenance atezolizumab 1200 mg every 3 weeks until completion of 1 year of atezolizumab. Primary end-point is invasive disease-free survival (iDFS) and secondary end-points include iDFS by PD-L1 and lymph node status, overall survival, safety, patient functioning and health related quality of life (HRQoL). Tumour tissue and blood samples will be collected for biomarker research. The first site was activated in May 4th, and approximately 430 sites are expected to be open globally in 30 countries. This trial is sponsored by Roche and conducted in partnership with the Breast International Group, Frontier Science and Technology Research Foundation, Institute Jules Bordet and Alliance Foundation Trials. Clinicaltrials.gov NCT03498716.
MEDIOLA: An open-label, phase I/II basket study of olaparib (PARP inhibitor) and durvalumab (anti-PD-L1 antibody)–Additional breast cancer cohorts

Susan M Domchek1, Sophie Postel-Vinay2, Seock-Ah Im1, Yeon Hee Park3, Jean-Pierre Delord4, Antoine Italiano5, Jerome Alexandre6, Benoit You7, Sara Bastian1, Matthew G Krebs8, Saiama Waqar1, Mark Lanasa1, Helen K Angell9, Mei Tang1, Christopher Gresty9, Laura Opincar1, Pia Herbolsheimer1 and Bella Kaufman10. 1Basser Center University of Pennsylvania, Philadelphia; 2Institut Gustave Roussy, Villejuif, France; 3Seoul National University Hospital, Seoul, Republic of Korea; 4Samsung Medical Center, Seoul, Republic of Korea; 5Institut Universitaire du Cancer de Toulouse, Toulouse, France; 6Institut Bergonié, Bordeaux, France; 7Hôpital Cochin, Paris, France; 8Centre Hospitalier Lyon Sud, Pierre-Bénite, France; 9Kantonsspital Graubuenden, Chur, Switzerland; 10The Christie NHS Foundation Trust and the University of Manchester, Manchester, United Kingdom; 11Washington University School of Medicine, Saint Louis; 12AstraZeneca, Gaithersburg, MD; 13AstraZeneca, Cambridge, United Kingdom and 14Chaim Sheba Medical Center, Tel Hashomer, Israel.

Background: Olaparib (Lynparza®) is a PARP inhibitor that alters the repair of single-strand DNA breaks. Durvalumab (Imfinzi®) is a monoclonal antibody against programmed cell death ligand 1 (anti-PD-L1) that promotes antitumor immune responses. MEDIOLA (NCT02734004) is a Ph I/II open-label, multicenter study enrolling patients (pts) across several tumor types (small-cell lung cancer, gastric cancer, germline BRCA-mutated [gBRCAm] BC, or platinum sensitive relapsed gBRCAm ovarian cancer). 34 pts with gBRCAm BC received olaparib 300 mg po bid for a 4-wk run-in, followed by olaparib 300 mg po bid and durvalumab 1.5 g IV q4 wks. Encouraging preliminary results support an expansion cohort in a BRCAm popn. Evidence suggests that mutations in other homologous recombination repair (HRR) genes may confer a BRCA-like phenotype, warranting an expansion of the study population beyond BRCAm.

Inhibition of vascular endothelial growth factor (VEGF) has been reported to enhance the efficacy of chemotherapy in TNBC. In addition, VEGF inhibition potentiates PARP inhibitor activity, particularly in pts who do not carry BRCAm. Combinations of immune checkpoint inhibitors and bevacizumab, an anti-VEGF-A antibody, have shown promising results in other tumor types. Thus, MEDIOLA will additionally explore the efficacy and safety of olaparib + durvalumab in combination with bevacizumab in TNBC pts.

Trial design: Pts in the additional MBC cohorts will receive combination olaparib and durvalumab with no olaparib run-in. Pts in the TNBC cohort will also receive concurrent bevacizumab 10 mg/kg q 2 wks. Tumor assessments will be performed at baseline and every 8 wks thereafter.

Eligibility criteria: Pts with histologically confirmed, locally advanced or metastatic HER2-neg BC, who are PARP-inhibitor and immunotherapy naïve. Prior anthracycline and/or taxane therapy in early or MBC is required. Prior platinum therapy is allowed, if there was no disease progression while receiving treatment and at least 12 mths has elapsed since the last dose. Pts will undergo BRCA and HRR mutation testing and will be assigned to a cohort based on their mutation status, as illustrated in Table 1.

Specific aims: Cohort-specific primary efficacy endpoint targets were calculated aiming for superiority to standard of care treatment (Table 1). Other primary outcomes are safety and tolerability. Secondary endpoints are PK, DCR at 24 wks, objective response rate, duration of response, progression-free survival and overall survival. Exploratory endpoints include the analysis of tumor-infiltrating lymphocytes and PD-L1 expression.

Statistical methods: The expansion cohort will have a single-stage statistical design. Bayesian predictive probability design will be used for the analysis of the HRRm and TNBC triplet cohorts.

Accrual: Accrual targets are shown in Table 1. First subject will be enrolled in Nov 2018.

Phase II study of atezolizumab, cobimetinib, and eribulin in patients with recurrent or metastatic inflammatory breast cancer (IBC)

Angela Alexander¹, Angela N Marx¹, Sangeetha M Reddy¹, James M Reuben¹, Huong C Le-Petross¹, Deanna Lane¹, Monica L Huang¹, Savitri Krishnamurthy¹, Yun Gong¹, Dan S Gombos¹, Nimisha Patel¹, Cynthia I Tung¹, Richard C Allen¹, Thomas J Kandl¹, Jimin Wu¹, Suyu Liu¹, Anisha B Patel¹, Andrew Futreal¹, Ignacio Wistuba¹, Rachel M Layman¹, Vicente Valero¹, Debu Tripathy¹, Naoto T Ueno¹ and Bora Lim¹. ¹University of Texas MD Anderson Cancer Center, Houston, TX.

**Background**: IBCs that do not completely respond to chemotherapy often have dysregulated immune pathways, and novel therapies are needed to improve outcomes in recurrent/metastatic disease. One-third of IBCs express the atezolizumab target PD-L1, and cobimetinib increases PD-L1 expression; thus, we hypothesize that atezolizumab and cobimetinib may act synergistically in IBC. The FDA-approved agent eribulin is active in IBC and has anti-stem cell activity and can reverse the IBC phenotype of epithelial-to-mesenchymal transition. Hence the use of eribulin as a chemotherapy backbone in combination with other novel agents is well justified.

**Trial Design**: This single-arm, open-label trial is enrolling patients with recurrent IBC or de novo metastatic IBC that has progressed on at least 1 line of standard chemotherapy. During a 4-week pharmacodynamic window, patients have an upfront biopsy, receive atezolizumab and cobimetinib treatment for 4 weeks, and have a second biopsy. Triple-combination treatment then commences, with standard eribulin dosing. After 4 cycles of eribulin, patients receive maintenance targeted therapy until disease progression or intolerable toxicity.

**Eligibility Criteria**: Patients with metastatic IBC of any molecular subtype must have measurable disease (per RECIST 1.1) amenable to biopsy. Patients with HER2+ disease must have received both pertuzumab and T-DM1. Patients with treated stable brain metastases are allowed. Patients must have recovered from the acute effects of any prior therapies and have adequate hematologic, organ, and cardiac function. Patients with autoimmune diseases or a history of pneumonitis are ineligible.

**Specific Aims**: The primary objective is to determine the overall response rate (ORR) of the combination therapy. Secondary objectives include determining the safety and tolerability, clinical benefit rate, response duration, progression-free survival, 2-year overall survival rate and predictive biomarker analyses.

**Statistical Methods**: The trial will enroll up to 9 patients in its phase I/safety lead-in portion and up to 33 patients total. A Bayesian optimal interval design is used to efficiently determine the maximum tolerated cobimetinib dose in phase I. Patients start cobimetinib at the FDA-approved dose of 60 mg/day with a target toxicity rate is 0.3. Phase II will enroll 24 patients to determine the efficacy of the triple-combination therapy. The historical ORR in metastatic IBC is 10%; our sample size provides 80% power to detect an ORR improvement to 25%.

**Accrual**: The trial has enrolled 7 patients since its start in August 2017.
Phase Ib clinical trial of coPANlisib in combination with Trastuzumab emtansine (T-DM1) in pre-treated unresectable locally advanced or metastatic HER2-positive breast cancer (BC) “PANTHERA”-CTRIAL-IE 17-13

Anees Hassan¹,²,⁷, Giuseppe Gullo³, Seamus O'Reilly⁴, Manuel Ruiz-Borrego⁵,⁶, Sinead Toomey¹, Liam Grogan¹,²,⁷, Oscar Breathnach¹,²,⁷, Patrick G Morris¹,²,⁷, Janice M Walshe³, John Crown³, Deirdre O'Mahony⁴, Alejandro Falcon⁵, Keith Egan⁷, Andrés Hernando⁶, Ausra Teiserskiene⁶, Catherine M Kelly⁸, Linda Coate⁸ and Bryan T Hennessy¹,²,⁷,⁸.

¹RCSI, Dublin 9, Ireland; ²Beaumont Hospital, Dublin 9, Ireland; ³St Vincent's University Hospital, Dublin 4, Ireland; ⁴Cork University Hospital, Cork, Ireland; ⁵Hospital Universitario Virgen Del Rocio, Sevilla, Spain; ⁶GEICAM, Spanish Breast Cancer Group, Madrid, Spain; ⁷Cancer Clinical Trials and Research Unit, Beaumont Hospital, Dublin, Ireland; ⁸Cancer Trials Ireland, Dublin, Ireland and ⁹Mater Misericordiae University Hospital, Dublin, Ireland.

**Background:** The phosphoinositide 3 kinase (PI3K) pathway is important in the oncogenic function of HER2. Aberrant activation of PI3K is implicated in resistance to trastuzumab and other HER2-targeted therapies and is frequent, with up to 22% of HER2 positive breast cancer having a PIK3CA mutation. Copanlisib is a pan-class 1 PI3K inhibitor administered i.v. with low nanomolar activity against both PI3Kα and PI3Kβ. Copanlisib has been shown to re-sensitise trastuzumab resistant cell lines to trastuzumab with synergism seen in some cell lines between copanlisib and HER2 targeted therapy.

**Trial design:** This is a phase Ib open label, single arm adaptive, multi-centre trial of copanlisib in combination with T-DM1. Eligible patients will receive T-DM1 at 3.6mg/kg i.v. on day 1 of a 21-day cycle plus copanlisib. Copanlisib will be administered i.v. according to the dose escalation scheme (dose level 1 is 45mg on days 1 and 8, dose level 2 is 60mg on days 1 and 8, dose level 3 is 60mg on days 1, 8, and 15). Dose level -1 will be 45 mg on day 1 in case dose de-escalation is needed. We will enrol 3 to 6 patients per dose level. All patients in each level must have completed at least the first cycle of therapy before enrolment in the next dose level. Patients not completing the first cycle for a reason other than toxicity will be replaced. Dose escalation and determination of the Maximum Tolerated Dose (MTD) will be based on the occurrence of Dose Limiting Toxicities (DLT).

**Eligibility criteria:** Eligible patients are those with unresectable locally advanced or metastatic HER2-positive BC who previously received trastuzumab and a taxane, separately or in combination. Participants must have adequate organ function and ECOG PS ≤ 2.

**Objectives:** The primary objective is to determine the MTD for copanlisib in combination with T-DM1 in patients with pre-treated unresectable locally advanced or metastatic HER2-positive BC. Secondary objectives include evaluating the safety, efficacy and cardiotoxicity in patients treated with this regimen. Exploratory objectives include examining for predictive biomarkers in tumour tissue and blood or plasma and to examine molecular tumour adaptation to clinical trial therapy.

**Statistical methods:** Patients will be accrued in cohorts of 3 patients according to a standard 3+3 algorithm, with dose escalation and determination of MTD based on the occurrence of DLT, using the usual threshold probability of 33%. The final dose level will be expanded to include a total of 6 additional patients (expansion cohort).

**Present accrual and target accrual:** The trial will start accrual in October 2018. Maximum of 24 patients will be enrolled.
An initial safety study of gedatolisib plus PTK7-ADC for metastatic triple-negative breast cancer

Milan Radovich¹, Jeffrey P Solzak¹, Bradley A Hancock¹, Anna Maria V Storniolo¹, Bryan P Schneider¹ and Kathy D Miller¹.
¹Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN.

Background: The PI3K pathway is dysregulated in the majority of triple-negative breast cancer (TNBCs). Contrary to the theory of oncogene addiction, single agent inhibition of the PI3K pathway in TNBC has had only modest activity. Our group has demonstrated preclinically that when PI3K is inhibited, an immediate compensatory up-regulation of the Wnt pathway occurs. The Wnt pathway is known for its role in cancer metastases and can confer resistance to initial PI3K inhibition. Simultaneous dual targeting of both pathways is highly synergistic against TNBC models in vitro and in vivo.

We have initiated a Phase I clinical trial using Gedatolisib (PI3K/mTOR inhibitor) and PTK7-ADC (Wnt pathway) for patients with metastatic TNBC (NCT03243331). Gedatolisib is a pan-class I isoform PI3K/mTOR inhibitor, and PTK7-ADC is an antibody-drug conjugate against the cell-surface PTK7 protein (Wnt pathway co-receptor) with an Auristatin payload. PTK7 is an attractive second target due to its up-regulation after PI3K inhibition and its known overexpression in TNBC. Further data has shown that the PTK7-payload, Auristatin, is in itself synergistic with Gedatolisib. The combination of using both of these drugs suggests a unique concept of “double synergy”. Where Gedatolisib increases the expression of the target of PTK7-ADC leading to one mechanism of synergy, and the Auristatin payload on PTK7-ADC is synergistic with Gedatolisib providing a second mechanism.

Study Design: This is an open-label, Phase I, dose-escalation study with a 3 + 3 cohort design. The trial will enroll 12-18 patients. 3 cohorts of at least 3 patients will receive Gedatolisib (weekly) & PTK-ADC (q3w) at 110mg+1.4mg/kg, 180mg+1.4mg/kg, and 180mg+2.8mg/kg dose levels.

Eligibility Criteria: This trial enrolls patients with metastatic triple negative (ER-, PgR-, HER2-) or low estrogen expressing (ER and PgR <5%, HER2-) breast cancer. Patients must have received at least one prior chemotherapy for advanced disease and have adequate hematologic, renal, and hepatic function. Patients with previously treated CNS involvement are eligible. Patients with uncontrolled diabetes are excluded, given the potential for hyperglycemia with Gedatolisib. Patients must have disease amenable and consent to biopsy for correlative endpoints.

Objectives: The primary objective is to evaluate the safety of Gedatolisib plus PTK7-ADC. The secondary objective is to evaluate efficacy as determined by objective response rate, clinical benefit at 18 weeks, and progression free survival (PFS). Exploratory objectives will evaluate efficacy in patients with genomic aberrations in the PI3K pathway; and association of tumor DNA, RNA, plasma and circulating tumor cell sequencing with clinical efficacy to identify putative biomarkers.

Correlative Sciences: We are collecting matched pre-/post-treatment tumor biopsies and serial blood samples to determine biomarkers of clinical response to inform subsequent trials. We plan to evaluate: 1) PI3K activity; 2) genomic aberrations in the PI3K pathway; 3) baseline PTK7 expression; 4) PTK7 upregulation after Gedatolisib treatment; and 5) mutations in plasma circulating tumor DNA.

Supported by the BCRF, 100 Voices of Hope, Catherine Peachey Foundation, and Pfizer.
Ixazomib in combination with carboplatin in pretreated women with advanced triple negative breast cancer, an ongoing phase I/II trial (AGMT MBC-10 trial)

Gabriel Rinnerthaler¹, Simon P Gampenrieder², Andreas Petzer³, Sonja Burgstaller³, Daniela Voskova⁴, Dieter Rossmann⁵, Marija Balic⁶, Daniel Egle⁷, Holger Rumpold⁸, Christian F Singer⁹, Edgar Petru⁶, Thomas Melchardt¹, Hanno Ulmer¹⁰, Brigitte Mlineritsch¹ and Richard Greil¹. ¹Salzburg Cancer Research Institute with Laboratory of Immunological and Molecular Cancer Research and Center for Clinical Cancer and Immunology Trials, Paracelsus Medical University Salzburg, Salzburg, Austria; ²Ordensklinikum Linz Barmherzige Schwestern, Linz, Austria; ³Klinikum Wels-Grieskirchen, Wels, Austria; ⁴Johannes Kepler University Linz, Linz, Austria; ⁵County Hospital Steyr, Steyr, Austria; ⁶Medical University Graz, Graz, Austria; ⁷Innsbruck Medical University, Innsbruck, Austria; ⁸Academic Teaching Hospital Feldkirch, Feldkirch, Austria; ⁹Cancer Comprehensive Center, Medical University of Vienna, Vienna, Austria and ¹⁰Informatics and Health Economics, Medical University Innsbruck, Innsbruck, Austria.

Background: Triple-negative breast cancer (TNBC) comprises a heterogeneous group of diseases which are generally associated with poor prognosis. Recently, the PARP inhibitor olaparib was approved as first targeted treatment beyond antiVEGF therapy for the BRCA1/2 mutated subgroup of TNBC. However, cytotoxic agents still remain the mainstay of treatment for this breast cancer subtype. Ixazomib is a selective and reversible inhibitor of the proteasome, which has been mainly investigated as treatment of multiple myeloma. In a preclinical cell line model for TNBC the first-generation proteasome inhibitor bortezomib showed synergistic efficacy with cisplatin. Clinical data are available for carboplatin plus bortezomib in metastatic ovarian and lung cancers showing remarkable antitumor activity (47% and 38% response rate, respectively) and good tolerability. In solid tumors cytotoxic effect of proteasome inhibitors is thought to be mediated through different mechanisms: (1) Inhibition of the Fanconi Anemia and BRCA1 DNA repair mechanism (2) Inhibition of p53 degradation (3) Inhibition of NF-kappa B signaling cascade. Based on this evidence, the phase I/II MBC-10 trial will evaluate the toxicity profile and efficacy of the oral second-generation proteasome inhibitor ixazomib in combination with carboplatin in patients with advanced TNBC. Trial Design: Patients with metastatic TNBC pretreated with at least one prior line of chemotherapy for advanced disease with a confirmed disease progression and measurable disease are eligible for this study. Patients will receive ixazomib in combination with carboplatin on days 1, 8, and 15 in a 28-day cycle. The phase I part of this study uses an alternate dose escalation accelerated titration design. After establishing the maximum tolerated dose (MTD), accrual continues to evaluate the efficacy and safety of the combination (phase II, including 41 evaluable patients). All patients will continue on study drugs until disease progression, unacceptable toxicity or discontinuation for any other reason. Primary endpoint of the phase II is overall response rate, secondary endpoints include safety profile, progression-free survival and quality of life. The MBC-10 trial is accompanied by a broad biomarker program investigating predictive biomarkers for treatment response and potential resistance mechanisms to the investigational drug combination. This trial is open for patient enrollment since November 2016 in six Austrian cancer centers. Accrual is planned to be completed within two years. ClinicalTrials.gov Identifier: NCT02993094
A phase Ib/II clinical trial investigating the efficacy of nitric oxide deprivation and docetaxel in triple negative breast cancer

Andrew W Chung\textsuperscript{1,2,3}, Joe E Ensor\textsuperscript{3}, Jorge Darcourt\textsuperscript{3}, Anna Belcheva\textsuperscript{3}, Tejal Patel\textsuperscript{3}, Jenny C Chang\textsuperscript{2,3} and Polly A Niravath\textsuperscript{3}.

\textsuperscript{1}Texas A&M University Health Science Center, Bryan, TX; \textsuperscript{2}Houston Methodist Research Institute, Houston, TX and \textsuperscript{3}Houston Methodist Cancer Center, Houston, TX.

Triple negative breast cancer (TNBC) is an aggressive disease that currently lacks an efficacious form of therapy. Although chemotherapy is the current standard of care for metastatic TNBC, the 5-year prognosis remains grim with a high rate of disease recurrence. Cancer relapse is thought to be initiated by chemotherapy-resistant breast cancer stem cells (BCSCs). These BCSCs give rise to a diverse clonal population that results in a heterogeneous cancer, which complicates targeted therapeutic strategies. Our previous studies revealed that BCSCs utilize inducible nitric oxide synthase (iNOS)-derived nitric oxide to promote their proliferation, migration, and self-renewal capacity. In an effort to target the BCSC population, we found that iNOS inhibition with NG-monomethyl-L-arginine (L-NMMA) sensitized BCSCs to docetaxel \textit{in vivo} in TNBC xenograft models, leading to decreased BCSC viability and tumor burden. These findings suggest that BCSC resist conventional therapy in a nitric oxide-dependent manner and that combination of L-NMMA with docetaxel will effectively target BCSCs to prevent further relapse. A phase Ib/II clinical trial was conducted to determine the maximum tolerated dose, recommended phase 2 dose (R2PD), dose-limiting toxicities (DLTs), and efficacy of the L-NMMA and docetaxel combination in TNBC patients with chemotherapy-refractory locally advanced or metastatic disease. For the phase Ib portion of the study, a standard Bayesian continual reassessment method is being used to investigate 7 dose levels of L-NMMA (5, 7.5, 10, 12.5, 15, 17.5, and 20 mg/kg) and two dose levels of docetaxel (75 and 100 mg/m\textsuperscript{2}). Sixteen patients have been recruited to date, and based on current pharmacokinetics, pharmacodynamics, and safety data, the RP2D is expected to be docetaxel 100 mg/m\textsuperscript{2} (Day 1) and L-NMMA 20 mg/kg (Days 1-5) every 3 weeks. Two and three patients received 15 mg/kg L-NMMA + 75 mg/m\textsuperscript{2} docetaxel and 17.5 mg/kg L-NMMA + 100 mg/m\textsuperscript{2} docetaxel, respectively. Of these 5 patients, one partial responder completed 8 cycles before discontinuing treatment due to taxane-associated neuropathy. Among the five patients treated at the RP2D, only one taxane-associated DLT occurred. The overall response rate for patients treated at the higher doses was 22.2%. Early results of the phase Ib/II trial indicate the safety, tolerability, and promising activity of the first-in-class pan-NOS inhibitor L-NMMA in combination with chemotherapy in the treatment of chemotherapy-refractory TNBC.
